Fig. 2. Expansion Joints in Floor of Swimming Pool

for the building was let to Godfrey & Hirsch, of St. Louis. The approximate cost was as follows: grading and shaping, $13,000; concrete, $9000; sand beach, $1000; building, $16,000; total, $39,000. The extension of the building will cost about $21,000, making a finished total of $60,000.

The Results of City Planning in Essen, Germany

By Harold M. Lewis*

The city of Essen, Germany, best known as the home of the Krupp Steel Works, and the center of the largest coal-mining and industrial district of Germany, has, in the last few years, come to be recognized as one of the leading cities in yet another development—that of modern city planning. It is especially interesting in this respect, as it is still under the impetus of a rapid growth, which first made apparent the need for a large and comprehensive street plan, and the growth of this new plan and the contrast between old and new methods can be readily observed at this time.

The population of Essen, on Mar. 1, 1914, was 325,259, an increase of 172% over the figures for 1900, which were 118,862. During this period several outlying districts were joined to the city and, further, such additions now under consideration will bring the total to nearly 500,000. In the year 1910, of the wage earners in the city, 92.15% were receiving annual incomes of only 216 to 720 dollars, and therefore the housing plans of Essen must provide for an enormous number of cheap homes. The problem of combining cheapness, attractiveness and healthfulness, however, is being successfully solved. The bettered conditions in the last respect is shown by the fact that in the years 1900 to 1910 the death rate of Essen was decreased from 25.81 to 12.45 per 1000.

Essen is situated on a high plateau, the largest part of which slopes northward to the Emscher River and a smaller section of which drops off suddenly toward the Ruhr River on the south and east sides. The problem of fixing upon a comprehensive and adequate street plan was complicated by several factors. First of all by the topography of the land, which is decidedly rolling and at the outskirts of the city is sharply cut by valleys running in various directions and which must be bridged over in order to afford a satisfactory prolongation of the main traffic streets. A second important factor is the presence of the Krupp Steel Works in the very center of the city and occupying a large site which is cut by comparatively few streets. There are also about fifteen coal mine shafts scattered over the city and the plants connected with these and their immense piles of stone wastes form yet another impediment to a complete street plan. Moreover, the city is covered by a network of railroads to furnish transportation facilities for the products of the Krupp Works and the various coal mines, and in many places subsequent crossings under these railways (they are practically all on embankments) cause long detours.

An examination of a map of Essen shows a very complete system of radiating streets leading toward the center of the city, but as these approach the old section they become almost hopelessly lost, as there are no adequately wide streets cutting across the old part of the city. There are, however, a couple of such streets already planned to relieve the existing conditions. This old section might be described as a series of squares and market places connected by narrow, winding and often hilly streets. It has been found necessary to place one track of the trolley line on Kettwigerstrasse on a back street, and the remaining track runs so close to the sidewalk that a pedestrian cannot safely walk too close to the curb. At the time of the daily closing of the Krupp Works this street presents a scene very similar to Nassau St., in New York City, at the noon hour.

A stranger passing from this section of the city to the new district south of the Central R.R. Station would at once notice a difference. The streets are much wider and many of them are attractively planted with trees and shrubbery. Public parks and lawns, which were noticeably absent in the old part of the city, are everywhere within easy reach. One similarity is apparent, and that is that the streets at first seem to be hopelessly tangled and crooked, but as soon as their arrangement is studied it becomes apparent that this is a carefully planned disorder.

The whole street system is worked out with the primary aim of a characterization of the streets, and there is probably no other city in which this fundamental German idea has been so completely developed. The aim of the planner was to furnish, throughout the city, constantly new and varied vistas, not only in respect to the houses and their relations to the streets, but also in the width and arrangement of the individual streets. The completeness with which this has been carried out is shown by the fact that the range of vision in the streets is, as a rule, limited to 650 to 1000 ft. The main traffic streets are often exceptions to this rule, but every opportunity has been taken to avoid monotonous stretches on these.

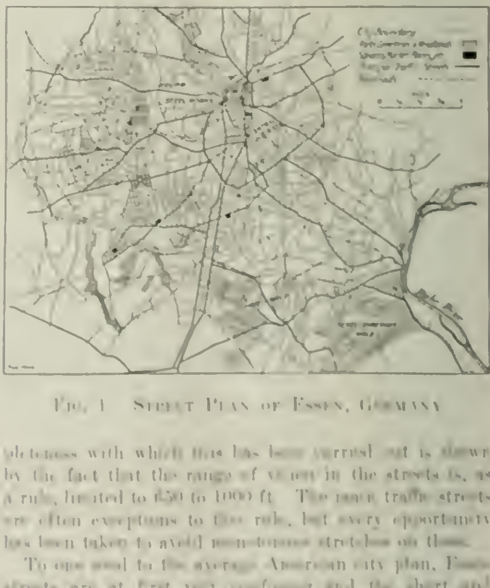

Fig. 1. Street Plan of Essen, Germany

To one used to the average American city plan, Essen streets are at first very confusing and the short and crooked streets perhaps lose some of their attractiveness when they become solidly built up to the sidewalk line with ordinary houses, and the lack of any long views may give a crowding and oppressive effect. A distinct advantage of the irregular system is the readiness with which large open places can be created at the main intersections by the cutting off of sharp corners, and advantage has been taken of this in Essen.

Not only do the streets differ from each other, but in many cases the individual streets are unsymmetrically arranged so as to avoid any chance of monotony. That is, the sidewalk is often a wide promenade on one side and an ordinary sidewalk on the other. Several very attractive streets are arranged with a single line of trees

*Engineer, [illegible]

FIGS. 2-6. SOME STREETS IN THE CITY OF ESSEN

(1. Beethovenstrasse, showing very narrow paved roadway and planting strip on one side. 2. Richard Wagnerstrasse, showing festooned vines in planting strip. 4. Moltkestrasse, an attractive curved street. 5. Kettwigerstrasse, in the old section. 6, Irmgardenstrasse, a typical short street in the new section.)

which are placed along a wide and principal footway. Another attractive arrangement is made with three rows of trees by placing the main footway between two of them on one side. Even the stereotyped system with two rows of trees is varied by surrounding one by a grass plot and the other with mosaic-stone pavement. Richard Wagnerstrasse has on one side an attractively planted parkway about 35 ft. in width between the houses and the main sidewalk, as seen in Fig. 2.

It has been attempted to segregate the residences in small groups each of which shall have its own retail stores. An open market place is also usually provided for each residence section. This plan has been greatly aided by the Krupp Co., which has established throughout the city a series of colonies for its employees. The most interesting of these are Magarethenhöhe, a colony for the Krupp officials, and Altenhof, in which the old and decrepit employees are provided with charming homes, each

designed for a man and wife. These colonies are among the most attractive parts of Essen.

The system of parks in the new part of the city was laid out with a view of placing one of the larger parks within five to ten minutes' walk from any section, and this has been practically realized. The total park area is not large, as it was in 1910 only 7.4% of the total area of the city, or about 191 sq.ft. per inhabitant. Essen is, however, much better off in this respect than this figure indicates, due to the large tracts of woodland just south of the city and along the Ruhr River. This district can be reached in fifty minutes by foot or twenty minutes by trolley from the center of the city and so is readily accessible and is much frequented by the people of Essen. There were in 1910 16.8 sq.ft. of playgrounds for each child in the city.

Essen is primarily a city of low buildings, and the tendency seems to be for the height to decrease rather than increase. This is in part due to the great chance of damage to high or large buildings due to the settlement of the land over the coal mines by which practically the whole city is undermined. Evidences of this settlement can often be seen in the old walls and buildings. The height of buildings in the city is distributed about as follows:

Four stories in height—10% of the total area.

Three stories in height—26% of the total area.

One or two stories in height—54% of the total area.

The group system of buildings has been well developed and has helped greatly in forming variety in the street fronts. Steep tile roofs are usually used, as giving a more attractive appearance and individuality than the monotonous line of flat roofs prevailing in the solidly built up parts of so many cities.

The results have been obtained with the aid of a strict building ordinance, a liberal land policy and a concentration of power under one head. As in most of the German cities the city is divided into several districts according to the use of the land and the regulations for each district are somewhat different. A summary of the restrictions for maximum height and unbuilt areas follows:

	District 1	2	3	4	5
Max. height of buildings	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Unbuilt area [illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
		[illegible]	[illegible]	[illegible]	[illegible]

Ordinarily, the height of a building must not exceed the width of the street it fronts upon, although under certain conditions an additional two meters is allowed.

The great detail with which the plans have been worked out can be illustrated by two examples, which are by no means exceptional. In Messelstrasse, one of the houses in a block of three-story houses was limited to two stories in height so as to afford from a neighboring street a view of a large and handsome school building. Again, in a plan recently made for an outlying section, arrangements have been made with the evangelical church association to build a large and monumental church at the proposed intersection of five main streets.

The entire plan for the new sections of the city and the modifications of the old plan were designed and are being carried out under the direction of Beigeordneter Dr. R. Schmidt, the chief engineering official of the city of Essen, to whom I am indebted for most of the above statistics.

The Teredo in Fresh Water—Contrary to general belief the teredo may exist in fresh water, as the following experience proves. The United States snagboat "Waco" was built about three years ago of long-leaf yellow-pine, with rake planks of oak. Before launching the hull was painted with

FIG. 7. A STREET IN THE KRUPP COLONY OF "ALTENHOF"

FIG. 8. A STREET VIADUCT CROSSING THE PARK

carbolineum. Soon after its completion at Jeffersonville, Ind., the "Waco" started on a trip to the Brazos River in Texas. Altogether the boat spent 2½ months in tide water, including the time working below Mile 19 in the Brazos River. The effect of the tide is perceptible up to this point, although there are no signs of barnacles or teredos in the wharves above Mile 25.

After passing Mile 19 the "Waco" spent the next two years and ten months working her way upstream to Mile 171, from which point she was returned and hauled out for repairs. An examination of the hull planking was made and found to be fairly well honeycombed by the teredo, necessitating the renewal of all bottom planking and the greater portion of the gunwales. Some of the specimens of the teredo that were examined were ⅛ in. in diameter and 18 in. long, all alive and healthy at the time the planks were removed.

The following analysis of Brazos River water taken at Mile 118 shows a high percentage of salt as compared [illegible] those that contained in samples taken from the Guadalupe River.

	Parts per million
Iron and alumina	11.[illegible]
Silica	14.[illegible]
Calcium carbonate	[illegible]
Magnesium carbonate	[illegible]
Sodium sulphate	[illegible]
Sodium chloride	[illegible]
Alkalinity, expressed as sodium bicarbonate	[illegible]

It is possible that the gradual transfer of the "Waco" from salt water to fresh, together with the natural saltiness of the river, has been a factor in preserving the life of some of the teredos that had gotten into its planks.

There is no doubt that the specimens were genuine teredos, as they showed all the characteristic features, and the holes left by them were lined with calcareous matter. [B. C. Mc[illegible] in the "Professional Memoirs" of the Corps of Engineers and Engineer Department at Large, July-August, 1914, p. [illegible]]

The Old Cleveland Trainshed Roof

The remarkable old trainshed roof of the Union Passenger Depot in Cleveland, Ohio, whose demolition was described in our issue of June 11, 1914, pp. 1294-1297, was a relic of early days of iron framing that merited close study by all structural engineers. It was built in the days when combination cast-and-wrought-iron construction was yet in flower. Like many other combination structures, it was highly individual, showing original ingenuity in every part.

A separate source of interest is the fact that, though the safety of the roof was at all times precarious (or at least none too ample) judged by modern standards, the roof stood almost half a century without accident or trouble. Alarm was raised concerning the structure about 40 yr. ago—in 1877—and again in the '80's was it criticized. Besides being doubtful in its iron framing, its expansion and contraction rocked one of the two supporting walls—in default of good roller construction. At one time, too, a storm actually broke some parts of the rod tie-work in the roof. But it suffered no vital accidents, and has remained until taken down, 49 yr. after its construction.

Reproductions of the two old drawings of the roof trussing are shown in Figs. 2 and 3 herewith. So far as can be determined, these drawings were made at the time of construction—one of them undoubtedly before construction, since the roof itself exhibited several departures from the drawing.

General Description

The trainshed was 600 ft. long. The roof trusses, spanning 180 ft. and spaced 12 ft. apart, were of double-pitched outline and looked something like ordinary roof trusses. But they probably were arches, as all the web members, except one strut on each side, were tension rods, forming a sort of spiderweb bracing system that suggests rigid arch-rib action of the rafters or upper chord. The web system includes a main tie-chord, an auxiliary tie or middle chord, and various diagonal tension rods. The strut near the lower third of either rafter was simply butted to its connections at top and bottom; it probably took only the local panel-load, and had minor effect (if any) in bracing the rafter against arch distortion.

The general design is such as to defy stress-analysis. But some approximate calculations lead B. R. Leffler, Bridge Engineer of the Lake Shore & Michigan Southern Ry., to state that the stresses in the truss may have been considerably in excess of 30,000 lb. per sq.in. under dead-load alone. He also states that the weight of iron in the roof is only half of what would be found in a structure of modern design, a fact which itself points to high stresses.

FIG. 1. INTERIOR OF CLEVELAND UNION DEPOT TRAINSHED, LOOKING ALONG THE LINE OF STRUTS

(Except for one strut on each side, all the web-members of the truss are tension members.)

Top Chord or Rib

The rafter or arch rib, 21 in. deep, was made of four wrought-iron bars, 6 in. wide by about 5/8 in. thick, with

[illegible] cross-shaped spreaders or spiders between, held together by pairs of assembly bolts running through from bar to bar. The drawings show only upper and lower flange bars, but in the roof itself every arch-rib had also two web bars (Fig. 4). These were apparently afterthoughts, as noted below. They were held apart by two sets of cast-iron angle or filler blocks in the upper and lower forks of each spider, seated against the middle rib of the spider arms, and notched for two through-bolts.

The spiders in the straight part of the rafter were planed square on the eight abutting corner-faces. Those of the middle part had their radial faces planed to a consistent taper, which made this part of the rafter a circular segment. An obtuse angle was formed at the junction of circular and straight portions, by a filler block at the upper flange, between adjoining spiders, welded to the upper flange bars.

The original plan (Fig. 2) appears to have contemplated using two narrow [illegible] bars each in upper and lower flange of the rib, instead of one 6-in. bar. The two easterly trusses of the trainshed were built this way, but all the other trusses had single 6-in. bars (Fig. 3).

The peculiar trainshed construction used in this roof was apparently used in some other buildings also. Old records of the Lake Shore at hand seem to show this. But no [illegible] are [illegible] below.

The [illegible] for the roof [illegible] were [illegible] to the [illegible] flange of the rib by the [illegible]. Of the two bolts at each cross, one

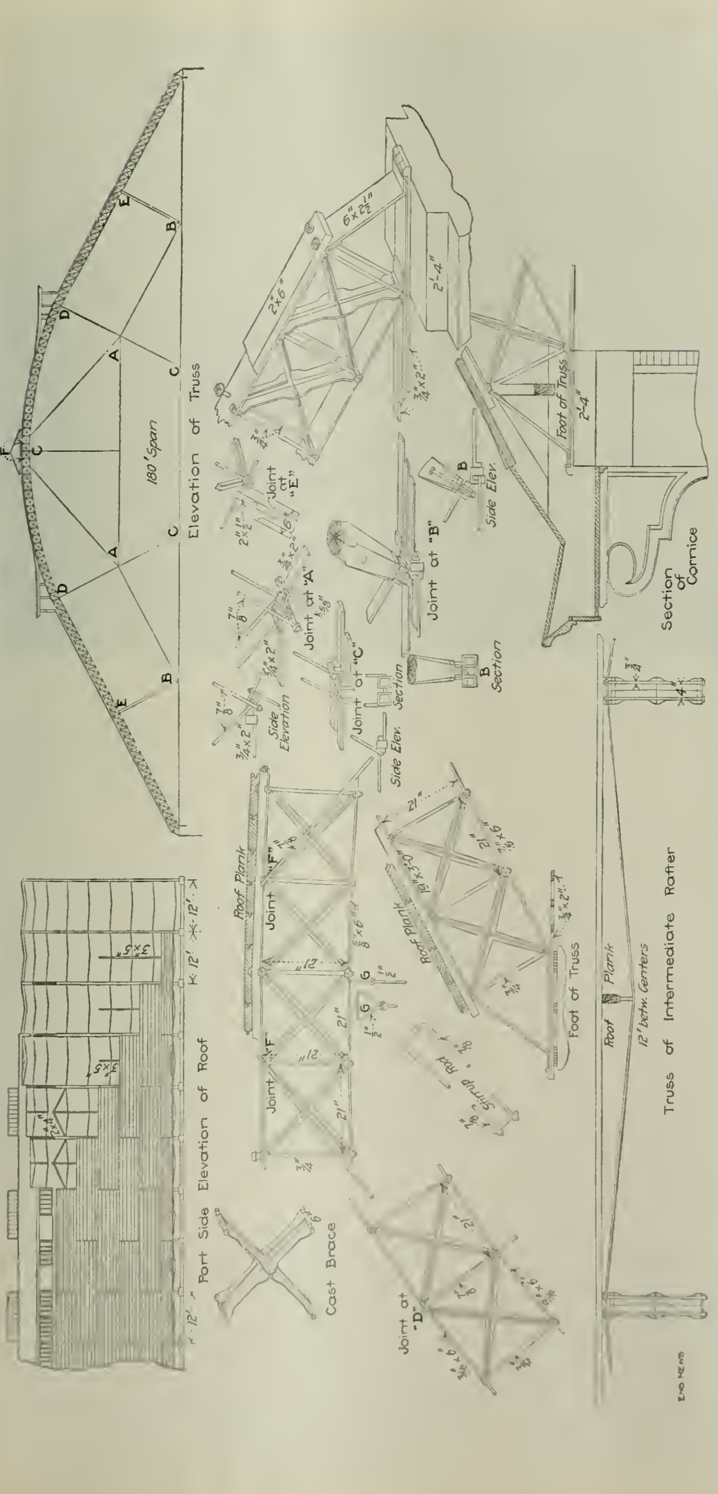

FIG. 3. DRAWING OF ROOF

Bearing title: "Iron roof truss, Union Passenger depot, Cleveland, Ohio."

had its nut raised about 2 in. above the top flange on a gas-pipe spacer, and this spacer passed through the spiking piece, and allowed the nut to secure it in place; the nut of the other bolt was seated directly on the flange bar.

The side bars, as already noted, were probably added after the roof was erected. Their most curious feature was a screw-joint at the beginning of the segmental crown portion. Here the pair of side bars of the lower part is terminated by a block between the bars, facing a similar terminal block of the side bars of the crown section. In the 5 or 6-in. space between the blocks was a right-and-left screw passing through both blocks, its middle part shaped to take a wrench. If these side bars were added some time after construction, to reinforce the ribs, this screw connection may have been used as a means of making the side bars share in the compressive stress carried by the rib.

Each rib was seated on and built into the wall masonry of the south wall of the trainshed, but at the north or lake-side wall was seated on a series of ¾-in. rollers, resting on the stone wall-plate. There was no evidence of motion at the roller bearing, and above the wall-plate the masonry was carried up to meet the roof planking, thus enveloping the arch ribs and tending to prevent expansion motion. This north wall was taken down in the demolition of the roof, and its masonry was found to be quite loose, i.e., not bonded by its mortar, and the horizontal joints of the wall in many places showed the en-

Fig. 1. Interior View toward Demolition Traveler, Cleveland Union Depot

(At the extreme right is the line of web struts corresponding to that seen in the middle of Fig. 1. The [illegible] middle part of the roof has only tie-rods in its web. The form and make-up of the arch rib are shown clearly in the silhouette of the [illegible].)

[illegible] of wall. From this it is believed that the trusses did not move on the wall, but that expansion and contraction of the ironwork was taken up by rocking of the wall.

The [illegible] strut in the web system (see Fig. 1) is shown in Fig. 2 as a 10½-in. [illegible] trussed with four ¾-in. rods. It was built as a [illegible] strut, however, and Fig. 3 shows it so. The latter drawing is therefore evidently of later date than Fig. 2, but, as some details, e.g., the connection of the diagonal rods at the crown, are not quite the same as there shown, it was probably made before the roof was built — as a final construction drawing perhaps.

Tension Members

The lower chord and the auxiliary tie or middle chord were made of flat bars ([illegible]). The splices in these bars were located at the joints of the web system, and were in all cases made as sketched in Figs. 5 and 6. Upset ends were forged, and these were hooked into each other and the joint then secured by slipping a welded square ring over the connection.

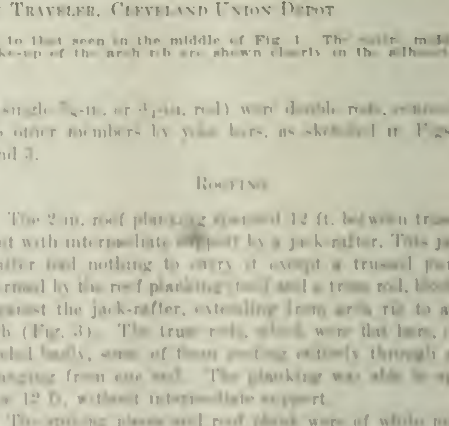
A [illegible] was found at all these joints. The welded wrought-iron ring was backed up by one or two [illegible], [illegible] so the joint [illegible]. The adjoining sketch, Fig. 6, shows such a ring, traced from the object. These must have been applied after the roof was erected, to strengthen the joint against [illegible] due to its eccentricity of pull, [illegible] on the wrought-iron rings.

The [illegible] members (except the crown hanger, a single ⅞-in. or ¾-in. rod) were double rods, connected to other members by yoke bars, as sketched in Figs. 2 and 3.

Roofing

The 2-in. roof planking spanned 12 ft. between trusses, but with intermediate support by a jack-rafter. This jack-rafter had nothing to carry it except a trussed purlin formed by the roof planking itself and a truss rod, blocked against the jack-rafter, extending from arch rib to arch rib (Fig. 3). The truss rods, which were flat bars, corroded badly, some of them rusting entirely through and hanging from one end. The planking was able to span the 12 ft. without intermediate support.

The springing pieces and roof plank were of white pine, the planks were fastened by wrought-iron nails. The covering was slate on tar paper, fastened with copper nails



Figs. 5-6. [illegible] and [illegible] Ring for Reinforcing the Tension Bar Splices, Cleveland Trainshed

FIG. 7. WEST WALL OF CLEVELAND UNION DEPOT

(The narrow masonry piers, and the cast-iron intermediate columns with plain base and cap plates, offer little resistance to a colliding train, yet they stood the full 49 years since 1865 without harm. At some time in that period the north intermediate column was taken out to make room for a crossover; the north pier buckled, and timber centering was put in to support the arch.)

None of the roofing material had been removed during the life of this structure, and at the demolition it was found in excellent condition.

For further details, the drawings, Figs. 2 and 3, can be referred to.

One fact bearing on the action of the roof truss in carrying load is to be noted. About 40 ft. inward of the south wall there was a longitudinal wall inclosing the waiting-room, etc., for the whole west half of the trainshed. The brickwork of this wall extended up to the roofing, and where it came under the bottom flange of the rib the brickwork had been built solid up against the iron. In the demolition the upper part of this wall was torn out. The result was a small but measurable deflection, $\frac{1}{4}$ to $\frac{1}{2}$ in., over the line of the wall, indicating that some of the roof weight had rested on the partition.

History

The front of the station building bears the date 1865, agreeing with the date on the first drawing (our Fig. 2). B. F. Morse, who died a few months ago, was Constructing Engineer for the structure. It is a remarkable coincidence that the train which carried his body to burial went through the trainshed on the very day when demolition of the old shed was begun.

Early records relating to the roof have not been found. A letter from Morse to John Newell, General Manager of the Lake Shore & Michigan Southern, written Mar. 26, 1877, is the earliest, aside from the two drawings here reproduced. Morse had become City Engineer of Cleveland in 1867, soon after completion of the trainshed, and was in this position at the time of writing the letter.

Criticism and Reinforcement

Mr. Morse's letter refers to criticisms of the roof, to a report made by a Mr. Wilson of Philadelphia, and to tests of some tension splices which the latter had made. It also relates that Mr. Morse made a private examination of the roof, and found the stress in the various tension joints to be not over 3 to 4 tons per square inch. He makes some suggestions for reinforcement; one of them shows (by sketch) side bars applied to the two lower panels of the rafter. This suggests that the side bars were added to the roof after 1877, and probably they were put on for the full length of each rafter, as found in the roof just demolished.

Later, in the early '80's, the roof was criticized and its strength declared doubtful, by S. W. Robinson, engineer to the Ohio Railroad Commission, but there is no record that anything was done to meet this criticism.

About 1885, a great north storm, blowing on the lakeside of the roof, broke a number of the crown diagonals on that side, at the same time buckling the corresponding south crown diagonals. The broken bars were replaced, and the roof appears to have suffered no permanent damage.

In recent years, the corrosion began to give trouble at some local points. As already noted, some of the jack-rafter truss-rods rusted through, but no attention was paid to this as the plank safely spanned the 12 ft. between trusses. But four years ago, in 1910, over a

point in the shed where engines of passenger trains stand were frequently and longer than elsewhere, the assembly bolts of the rafters (the bolts passing through from upper to lower flange plates) were found to be seriously weakened by corrosion. All the badly weakened bolts, in fact about one-fourth of all the bolts in the roof, were replaced, one by one, by steel bolts—the original ones were wrought iron. These rafter assembly bolts were important as they prevented the collapse of the rafter, and consequently that of the whole roof.

Last fall it was found that the new steel bolts were corroded almost as badly as had been the wrought-iron bolts, which they replaced, three years before. This fact made it clear that the problem of maintaining the roof was likely to become exceedingly difficult. A specially thorough examination of the roof, extending over two months (and not completed even in that time) further emphasized the difficulties attendant upon frequent close inspection and repair. With further regard to the indeterminate system of the trussing, and the probable high stresses existing in the main members, the engineers when called upon for definite assurances as to the safety of the roof declared the roof unsafe. Plans for its demolition were started at once, and were carried out during May and June, 1914.

Condition of the Iron

The ironwork of the roof shows almost negligible corrosion in its main members. The cast-iron spiders of the rafters are practically free from rust; the flange bars and large tension bars, while rusty, do not seem to have suffered much loss of section. The rafter-assembly bolts were much rusted, as noted above, and similarly the thin flat tension bars of the jack-rafters and the crown hangers of the trusses lost much from rusting. These exceptions, however, form only a small part of the total ironwork of the roof. Considering the severe exposure to locomotive gases, steam and atmospheric moisture, the condition of the roof is remarkable. In those parts of the framework south of the waiting-room partition, i.e., outside the open (train-shed) space, the iron is almost perfectly preserved, being barely tarnished.

The woodwork of purlins, etc., is as well preserved as the iron. The slate and tar-paper covering protected it fully from decay.

The removal of the old roof was wholly a safety measure, as the new Union Station now being planned for will be located half a mile or more to the eastward. The platforms of the old station are being covered by butterfly sheds pending completion of the new station.

The data for the preceding description were given by B. R. Leffler, Bridge Engineer, Lake Shore & Michigan Southern Ry., Cleveland, Ohio, who is in charge of the demolition work and previously was responsible for the maintenance of the roof. The copies of the old drawings were also obtained through his courtesy.

Coal, the Contractor and the Lien Law

An interesting decision was handed down in February by the New York Court of Appeals to the following effect as stated in the syllabus:

Coal sold to a contractor and builder of a state highway and consumed in generating steam in the boilers of road rollers and traction engines used on the contract, is not material furnished in the construction of the highway, within the meaning of the Lien Law and is not therefore the subject of a lien (Sec. 5 of Lien Law).

It happens not infrequently that arguments arise as to just what material should be considered as entering into construction work. In the case under consideration the point to be decided was whether coal sold to a contractor and builder of a state highway and used in the boilers of road rollers and traction engines on a contract, was a material furnished for the construction of the highway, within the meaning and intent of Sec. 5 of the Lien Law, which reads as follows:

> A person performing labor for or furnishing materials to a contractor, his subcontractor or legal representative, for the construction of a public improvement pursuant to a contract by such contractor with the state or a municipal corporation, shall have a lien for the principal and interest of the value or agreed price of such labor or materials upon the moneys of the state or of such corporation applicable to the construction of such improvement, to the extent of the amount due or to become due on such contract, upon filing a notice of lien as prescribed.

The Court held that inasmuch as the coal was not applied directly to the highway or absorbed by it, the price of the coal in question was not a lawful subject for the lien.

In supporting its conclusions the Court referred to other important decisions on this same point. One of these decisions read:

> We are of the opinion that there is a plain distinction between materials so used [coal burned in engines used on work] and materials that enter directly into the work and become a part of it, or those that are consumed by being applied directly to substances to be moved or changed to make a place for the structure or be incorporated into it.—[Sampson Co. vs. Commonwealth, 202 Mass., 326.]

The decision of the Court of Appeals on this point recalls other decisions in this same field. It has been held that materials used in a coffer-dam constructed especially to make possible the building of the dam contracted to be built and which were in effect destroyed by their use in the coffer-dam or subsequent loss were the lawful subject of a lien.

As illustrating distinctions which must be drawn in defining materials used directly on road construction, other decisions of the New York Court of Appeals have held that dynamite used in breaking up frozen earth so that excavation could go forward was material furnished for the improvement of real property, and its furnishing the lawful subject of a lien. On the other hand, the rent of a steam shovel leased to a contractor for use in the construction of a public improvement, is not the lawful subject of a lien inasmuch as the machine after the construction work is completed is in practically the same condition as it was before the work was started.

The decision as regards the attachability of coal used in the operation of a contractor's plant appears to be very fair. Had the decision been otherwise, much confusion would follow, for it might be argued upon the same principle, that oil used in the lubrication of contractor's tools, and even food eaten by laborers and perhaps clothing worn by them, are all consumed in the construction of a building or other structure and hence are lienable materials. While this might not be true, such materials have neither physical nor immediate connection with the structure at any time. They are auxiliaries which make possible the operation of tools, machinery or men, which in their turn act upon the structure. This decision will probably be widely quoted.

Editorials

Commercial and Engineering Opportunities in South America

Never was there a more opportune time to press the introduction of American products in the development of the great engineering, mining and industrial enterprises of our South American neighbors. With all the other industrial countries of the world busy destroying one another, with no safe Atlantic merchant marine but that which plies between the American republics, the time has come for South America to turn to us for many manufactures which cannot now come from Europe.

Particularly timely, then, is the detailed account of the constructional activity of one of the most active of our Southern neighbors, a field which has already been extensively entered by American engineers and manufacturers. We recommend a perusal of the article on another page of this issue, "Recent Railway Construction in Chile," to manufacturers of railway and contractors' equipment. The author, Mr. King, has recently returned from a long business engagement in Chile, and has made his article specific enough to be of much value to live and foresighted American manufacturers.

It should be remembered, however, that Chile is but one of several of our prosperous South American neighbors who can no longer look to Germany, Belgium and England for locomotives, cars, steel and other equipment. When these South American countries once begin the extensive introduction of American products, let the manufacturers see to it that those products will ever afterwards be preferred.

With the right kind of commercial relations more friendly and intimate communication is inseparable, and the opportunity for American engineers to coöperate with their Southern brethren in great wealth producing enterprises must become greater than ever before.

An Object Lesson in City Planning

The average engineer, especially the engineer who has no connection with municipal work, probably regards city planning as a sort of amiable fad, with very little relation to the practical conditions and possibilities of American cities. If any such engineer, however, has the good fortune to visit the cities of modern Germany and view them with his eyes open, he soon realizes that city planning is something of enormous importance and enormous possibilities.

Elsewhere in this issue we publish an interesting account of what city planning has accomplished in the City of Essen, Germany, written for ENGINEERING NEWS, by Harold M. Lewis (son of Nelson P. Lewis, Chief Engineer of the Board of Estimate and Apportionment of New York City). Essen has become world-famous as the center of the great Krupp iron and steel industry. The Krupp works themselves form the nucleus about which the city has grown, and the shafts of numerous coal mines also emerge in the heart of the city.

Most American engineers know pretty well the appearance of the average American industrial town in the coal-mine and steel-making sections of Pennsylvania or Ohio; the long lines of dreary hovels in which the workmen live, the crude tawdriness of the business streets; the heaps of discarded tin cans; the tumble-down shanties and sheds; the barren hills and valleys surrounding. All these are only too familiar. The American who visits Essen, expecting to find there such sights as these, familiar in an American industrial city, has the surprise of his life awaiting him. Mr. Lewis' description and the photographs accompanying his article do faint justice to the beauty of streets and parks and buildings in this German city, where 90% of the workers earn less than $700 a year.

These beautiful results in city planning at Essen are obtained by comparatively simple means. Compare the variety in the street plan of Essen with the monotonous checkerboard regularity governing the layout of streets in almost every American city. Compare the narrow, well paved, well kept streets of Essen and their liberal provision of space for grass and trees, with the streets of the average American city, all laid out to one uniform width, and presenting usually a narrow strip of macadam or paving lined on each side with a broad stretch of weeds. Essen and other progressive German cities show the possibilities from *planning* a city's development, instead of letting it proceed on the plan of Topsy, who "just growed."

A Belief in a Shortage of Engineers

An Arkansas correspondent sends us an editorial in the "Christian Science Monitor," entitled "Why a Shortage of Engineers," containing the statement that "never before has the demand for civil engineers been so far ahead of the supply." Our correspondent remarks that from his own observations in recent travels over the country he found a situation exactly the reverse.

It should be added that the journal referred to based its statement as to the shortage of engineers on the report that the railway valuation work under the Interstate Commerce Commission was proceeding slowly because the U. S. Civil Service Commission had not yet been able to supply enough junior engineers for the work of surveying.

It is evident that the "Christian Science Monitor" has formed an opinion on very limited evidence. Those who are directing the work of railway valuation preferred to go ahead rather slowly at the start and test their methods by actual trial before putting parties at work in all parts of the country. There was at one time, in-

[illegible] some difficulty in securing certain men for special work on the valuation force under the conditions and the salaries offered, but it is a very far cry from such a condition to the conclusion that there is a shortage in the supply of good engineers.

The Cost of Building the Panama Canal

The widely published official figures of the cost of the Panama Canal have possibly given the general public an exaggerated idea of the cost of the canal as a piece of engineering work. The statement has been made that the entire cost of the canal to the United States when completed will be in the neighborhood of $400,000,000, and it is a natural conclusion that the bulk of this expenditure has gone into the work of digging the canal and constructing the locks.

It will surprise many engineers even, we doubt not, to learn from figures published in the last number of the "Canal Record," that up to Mar. 31, 1914, the entire expenditure on the canal in the Department of Construction and Engineering had been only $201,087,000. The total expense up to the same date for all purposes connected with the canal was $322,651,000. The chief items in the account, apart from construction and engineering, were in round numbers, civil administration, $7,000,000; sanitation, $17,000,000; fortifications, $5,000,000, and general items, $90,000,000. Under this latter head are included the payment of $40,000,000 to the French Canal Co. and $10,000,000 to the Republic of Panama. There is also included under this head very heavy expenditures for the reconstruction of the Panama R. R., the construction and repair of buildings and the cleaning up of the cities of Colon and Panama. Of course, all these expenditures were necessary to the canal work, but it ought to be more generally understood that in the actual building of the canal, including the cost of the machinery used in its construction, the entire expenditures have only been, in round numbers, $201,000,000.

Rerailing Frogs Protect Bridges

Derailment of a train is serious enough anywhere along the railway line, but it is most serious when approaching or upon a bridge. For a long time it has been the ideal of bridge engineers to make the roadbed just as safe over a bridge as it is elsewhere, to create structures which will carry the normal roadbed across the opening in such a way that both the operating department and the maintenance department need no other notice than that a bridge is there. Perhaps that ideal may be reached in the future. At present we are still very far from it. Means for protecting bridges from the special danger of a derailed truck or axle on a bridge have therefore been often discussed, time and time again, beginning many years ago.

"Engineering News" only a short time ago (Apr. 30, 1914, p. 991) suggested that in many cases a marked advantage may be secured in the direction of safety by erecting fender or buffer posts along the track or at the approach to a bridge. This introduced a distinctly new element into the discussion. The [illegible] wreck on the New Haven and the [illegible] bridge wreck on the Wabash gave special point to the suggestion. Now comes news that a less radical and more generally known expedient offers such increase of safety as to make its adoption a plain matter of good business.

The danger of derailments on a bridge lies not only in the chance that the projecting car may strike the trusses and thereby break down the bridge, but also in the probability that the derailed truck or axle will tear up the bridge floor. Rerailing frogs, placed in the inner guard-rails on the approach to the bridge, eliminate this danger by catching the derailed wheels and guiding them back to place on the rails. The Pittsburgh & Lake Erie Ry. uses this arrangement at nearly all of its bridges. The experience of that railway, we learn, indicates that the rerailing frogs are effective in taking care of derailed wheels. The track-inspection men report, from time to time, that marks of derailment show on the track, and that they disappear at a rerailing frog: clear evidence that a derailed axle was prevented from doing extensive damage to a bridge, with the chance of wrecking a train.

A single train wreck may easily cost more money than enough to place rerailing frogs at all the bridges of a fair-sized railway system. If one wreck a year is prevented by them, are they not a good investment?

The Utilization of the Catskill Water-Supply in New York City

It is expected that the new Catskill water-supply will be available for distribution in New York City by Jan. 1, 1916. A report has recently been made by I. M. de Varona, who has just been retired as Chief Engineer of the Department of Water Supply, Gas and Electricity, of New York, setting forth a proposed plan for the utilization of the Catskill supply by the city.

Contrary to the popular belief, the volume of the new Catskill supply now developed will be less than that now taken from the Croton watershed. Croton water, therefore, will continue to be used and the Catskill supply will serve to supplement it. The area of the Croton watershed drainage area is 360 sq.mi. The area of the Esopus drainage area, the only part of the Catskill water-supply now developed, is 255 sq.mi. Eventually, however, it will be possible to supplement the supply from the Esopus watershed with water from the Rondout, Schoharie and Catskill drainage areas, with an additional area of 522 sq.mi. This will make a total area available on the west side of the Hudson River of 777 sq.mi.

Mr. de Varona's report, however, deals only with the Esopus water-supply now to be available. The estimated safe yield from the Esopus is set at 250,000,000 gal. per day. This may be compared with the 336,000,000 gal. which is the estimated safe yield of the present Croton supply, and 150,000,000 gal. per day which Brooklyn now receives from its driven-well system on Long Island. The most important feature in connection with the new Catskill supply is that it will be delivered to the Borough of Manhattan at a head of 295 ft. above tide water.

The present Croton supply comes to the city at so moderate a head that large areas of the city located on high ground have to be supplied by pumping the Croton water. The Brooklyn supply being from driven wells, all requires pumping. The first use of the Catskill water, therefore, will be to supply the high areas in all the bor-

oughs and do away so far as possible with the expense of operating pumping machinery. In the accompanying two tables, Mr. de Varona summarizes the water consumption in each section of the different boroughs supplied at a different pressure, and in the second table he indicates the future supply for each of these various services.

Based on the estimated consumption for 1915, the water consumption for the various services in the different boroughs of New York is shown in Table I.

TABLE I.

Borough	Service	Elevation of normal water-level, ft.	Estimated consumption m.g.d.
Manhattan	Tower	336	0.5
	High	280	26
	Intermediate	218	66
	Low (*)	119	173
Bronx	High	290	15
	Intermediate	193	33
	Low (*)	134	22
Brooklyn	High	260	12
	Intermediate	200	16
	Low	172	108
Queens, 1st and 3rd wards	High	250	16
Richmond	High	453	1
	Intermediate	330	3
	Low	228	9

Table II shows the order and distribution of the sources of supply for each service after the introduction of the Catskill supply, the selection being based on hydraulic gradient and cost.

TABLE II.

Borough	Service	Primary source (*)	Secondary source
Manhattan	Tower	Catskill pumped	Catskill pumped
	High	Catskill full pressure	Catskill
	Intermediate	Catskill reduced pressure	Croton pumped
	Low	Croton	Croton
Bronx	High	Catskill full pressure	Catskill full pressure
	Intermediate	Catskill reduced pressure	Croton pumped
	Low	Croton	Croton
Brooklyn	High	Catskill full pressure	Catskill
	Intermediate	Catskill reduced pressure	Catskill
	Low	Catskill reduced pressure	Brooklyn system
Queens	First ward	Catskill full pressure	Catskill or Bklyn. system
	Third ward	Catskill full pressure	Queens system
Richmond	High	Catskill pumped	Catskill
	Intermediate	Catskill pumped	Catskill
	Low	Catskill full pressure	Southfield Blvd. station

(*) Primary source is the supply to be utilized in 1916 for the given service. The secondary source is the supply that will be drawn on when the increased demand necessitates a re-adjustment of the sources of supply.

It will be seen from these tables that Catskill water will be utilized to supply all of Brooklyn, Queens and Richmond, and all of Manhattan and the Bronx, except those areas now on the low pressure. These low-pressure areas, however, at present use about 195,000,000 gal. of water per day, so that they will form an important part of the water consumption. This will leave nearly 150,000,000 gal. a day of the Croton supply and the entire Brooklyn driven-well system available to supplement the Catskill supply whenever increasing water consumption makes it necessary.

It must be remembered that the 250,000,000 gal. estimated as the safe yield of the Esopus watershed is estimated on the basis of what it will yield year in and year out, including seasons of extreme drought. Inasmuch as the city has the large storage of the Croton watershed and the Brooklyn driven-well system to fall back upon in case of emergency, it will be feasible to draw a much larger supply than this from the Catskill watershed without serious danger.

In addition to this, Mr. de Varona recommended, in a report made to the Commissioner of the Department, on Nov. 21, 1913, that pumping machinery be installed to raise the pressure of the Croton supply, especially in those areas of the city where the height of the buildings necessitates the general use of pumps and tanks by the individual consumers. It is estimated that not less than $1,000-000 per year is spent by water consumers in this district for repumping the Croton supply to force it to the higher stories. The additional pressure upon the supply in this district resulting from installing city pumping stations would also increase the efficiency of fire-protection all over this area, which includes many congested-value districts not already covered by the high-pressure fire system.

It may very likely seem that the new water-supply from the Catskills will furnish such an unlimited amount of water that it can be used and wasted *ad libitum*. If this idea prevails, however, it will be a very short time indeed before New York will have to start up the pumping machinery which will be laid aside when the Catskill supply is introduced and only a very few years before the danger of water shortage will again menace the city.

Mr. de Varona presents a table showing the estimated average consumption of Greater New York from 1915 to 1925, assuming that no introduction of water meters and no systematic waste prevention are undertaken after the Catskill supply is introduced. The total available supply from the Esopus, Croton and Long Island drainage areas, with the small amounts from the Bronx and Bryan Rivers and the local water-supplies used in the Boroughs of Queens and Richmond, totals a safe yield of 766,000,000 gal. per day. Mr. de Varona's tables show that in 1920, only four years after the introduction of the Catskill supply, the water consumption of Greater New York, assuming as before that waste goes on unrestricted, will be 775,000,00 gal. per day, or greater than the safe yield of all the supplies now available. If, however, New York City will proceed with the introduction of water meters to restrict its waste, then Mr. de Varona estimates that the combined supplies now available will be sufficient until the year 1925.

This means, however, that in a very few years the city will again have to go to the expense of pumping a large part of its supply. The only way to obviate this would be to proceed with the development of the Schoharie, Rondout and Catskill supplies to supplement the flow of the Esopus. These can be developed at comparatively small expense and the aqueduct from Lake Ashokan in the Esopus watershed to New York City has been made of a capacity sufficient to carry the water from these additional drainage areas. These three additional areas will contribute a safe yield of 234,000,000 gal. a day to New York City. If waste is allowed to proceed, however, and water meters are not introduced, even this additional vast amount of water will be all required by the year 1926, according to Mr. de Varona's figures.

It is clearly evident, therefore, that New York should proceed at once to supplement the flow into Lake Ashokan by driving the Schoharie tunnel. It should also proceed with the introduction of water meters over the entire area of Greater New York. The total cost to the city of the water now supplied to the various boroughs averaged $18.80 per million gallons. The total cost of the Catskill supply from the Esopus watershed will be $97 per million gallons. This cost will be very greatly reduced, however, when the flow through the Catskill aqueduct is increased by the addition of the water from the other Catskill drainage area.

It is entirely clear that New York's great and costly water-supply ought to be carefully conserved. Abundant though it seems to be, the wisdom of proceeding diligently with the introduction of water meters and measures to prevent waste is proved by Mr. de Varona's figures.

Letters to the Editor

Air Valves on Water-Supply Lines

Sir—The discussion concerning air valves on water-supply mains, in your issue of July 30, is interesting and valuable. The writer agrees thoroughly with the main conclusions of Mr. Berry. As a corollary he remembers a case where a pipe some two miles long, extending from a pumping station to a reservoir, was full of water. The gage pressure at the pumping station indicated 120 lb. per sq.in.; no water was being supplied by the main, and the pumps were stopped. A valve near the reservoir was closed and immediately the pressure dropped in the pumping station from 120 lb. down to 105 lb., although the valve was at the same elevation as the water in the reservoir. This illustrates the simple phenomenon that might ordinarily be overlooked, that as soon as a valve is closed tight on a single line, in which no flow of water occurs, the pressure at the low point will immediately drop to that which would be caused by the highest elevation of water between the valve and the gage, less the atmospheric pressure. If the main were absolutely tight, the pressure would doubtless remain at the original amount, but the slightest leakage, which exists in all practical cases, would produce the phenomenon above described.

J. W. LEDOUX,

Chief Engineer, American Pipe & Construction Co.,
Philadelphia, July 31, 1914.

Promoting Safety on Construction Work in Wisconsin

Sir: An editorial in ENGINEERING NEWS of July 16, suggests that greater attention to the safety of workmen on construction jobs will result from New York's new Employer's Liability Law. In Wisconsin, some of the opinions and predictions of that editorial have already been verified by experience.

In Wisconsin, both factory inspection and the administration of the Compensation Act have for three years been carried on by the Industrial Commission. Until recently the time and money available for safety work have been directed toward the prevention of accidents in shops and factories; this year the Commission has started a similar campaign in construction work.

Only a small percentage of accidents can be prevented by law, which is, however, a necessary foundation for further work. The Wisconsin law simply requires that all places of employment shall be made safe; the Commission is to fix reasonable standards of safety. The "General Orders on Safety in Building Construction" (only 30 in number, and very brief) were drawn up by an advisory committee, composed of four building contractors and four labor-union representatives. The orders cover the following subjects: Scaffolds, openings in floors; ladders, elevators, derricks and other machinery; temporary floors on skeleton buildings; piling of material; notes on stepping on nails, and first-aid outfits.

The enforcement of these orders requires inspection. Such inspection—and in fact the entire department—not only must be nonpolitical, but must be free from any violent partisanship as between capital and labor. Inspectors must be men who understand that the success of their efforts consists in arousing the sympathetic interest of the employer in safety, rather than in detecting technical violations of the law.

The Commission's records show that over 80% of building accidents are caused by carelessness. Such accidents cannot be prevented by laws or by mechanical safeguards only.

The Commission has distributed a "Safety First" poster suitable for posting on the job, containing simple instructions to workmen regarding the most common causes of accidents. Every month it sends out copies of typical accident reports, which especially illustrate the disastrous effects of carelessness. These reports also can be posted on the job.

The best way to secure the interest and coöperation of workmen in eliminating carelessness and reducing accidents, is to give the workman an active part in promoting safety. On a small construction job the "safety organization" may consist simply of one man in each gang, appointed as safety inspector to report all dangerous conditions to the foreman. The man chosen for this work must naturally be reliable and observing and should preferably be one whose duties take him about the job. This plan is now being tried out in Milwaukee. On larger work there should be frequent meetings of the different foremen to take up questions involving more than one gang, such as ironworkers dropping tools or rivets on masons below.

On a large job a safety man might well be employed. In large industrial plants the safety man is now recognized to be just as necessary as the master mechanic or the chief electrician. He acts as secretary of the central committee and keeps track of everything on the job which pertains to safety.

SIDNEY J. WILLIAMS, Building Inspector,
Wisconsin Industrial Commission.

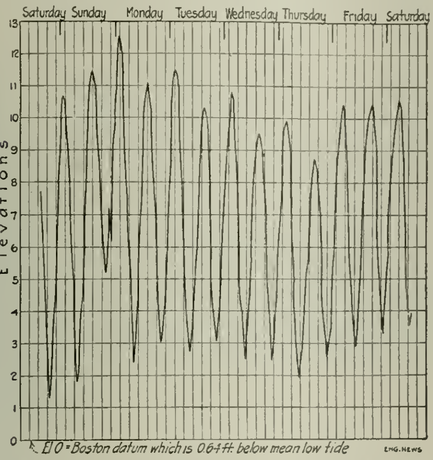
Madison, Wis., Aug. 4, 1914.

Abnormal Tide Fluctuation at Boston

Sir—Although a continuous record of the height of tide-water in Boston Harbor, at the Charles River Dam, is kept by means of an automatic water-stage recorder, the man on duty on the wall of the lock is required to observe the stage of the tide every half-hour and to enter it in a book.

When, one Monday morning, early last March, the lock operator examined the book and found that, during the

previous night, the tide had apparently failed to go down to the normal stage of a low neap tide by 2½ ft., and that after rising 2 ft., it had apparently changed its mind and gone down again more than a foot before finally ris-



TIDE RECORD AT CHARLES RIVER DAM, BOSTON, FEB. 28-MAR. 7, 1914

ing, and that in addition, when it did come in, it rose to the height of a spring tide before receding, he quite naturally accused the observer of inability to read the height on the gage board.

The lock-man maintained that he was right and the dispute was settled by examining the automatic gage record shown herewith, which showed that the peculiar fluctuation had actually taken place.

The explanation is, of course, that a strong easterly wind, by blowing the sea-water in, first prevented the tide from flowing out and that it caused a small rise in the upper harbor before the tide actually turned. A slight subsidence in the wind then permitted an ebb which was soon overcome by the incoming tide which, also on account of the assistance of the east wind, proceeded to rise to a greater height than is usual for neap tides. The wind had stopped by Monday morning and the tidal fluctuations again became normal.

E. C. S.

Boston, Mass., July 28, 1914.

The Cleveland Municipal Electricity Rates

Sir: Responding to an implied invitation to criticize the figures in ENGINEERING NEWS, July 30, upon Cleveland's new municipal electric plant, I beg to ask if the total cost of the power plant of $50 per kw. of capacity means the installed capacity of 25,000 kw., or the commercial capacity to deliver energy to the switchboard for distribution and use? The figure of $50 per kw. would indicate that the former is the case. If so, I submit that it is not good practice to undertake to deliver the installed capacity of the plant, and if I am correct, the cost per kilowatt of the true capacity of the station is in excess of $50, by an amount depending upon the figure which represents such true capacity.

Is there not an error in the figure of 0.52c., which is given as the cost of distribution alone in the case of the Brooklyn plant? If, as stated, the total operating cost of both generation and distribution for the Brooklyn plant last year was 1.49c. per kilowatt-hour, and of this the station cost was 0.79c., the cost of distribution alone should be 0.7c.

There are other criticisms which may be made of the figures used, some of which are noted in the article. There also seems to be an opportunity to criticize the ethics of the proposition that a business having been developed by private capital, a municipality should by competition in such business force rates to a basis determined solely by the cost of construction and operation of the most modern facilities for performing the service.

FRANK SILLIMAN, JR.

Philadelphia, Penn., Aug. 6, 1914.

[The 0.79c. mentioned by our correspondent above should have been printed 0.97c., as noted later on the same page. This leaves the 0.52c. as correct. In regard to the other parts of the letter, it should be noted that the discussion in question attempted only to present, so far as we could ascertain, the tangible basis on which the Cleveland officials based their hopes of financial success with their 1c.-3c. electricity supply.

There are numerous obvious manipulations of the figures there presented, which may be of interest in further examining the chances of success, although it was not considered desirable to make all the possible arrangements. Among such is the proportion of installed station capacity to be considered as a reserve. Further, taking the figures used, assessing fixed charges on peak-load customers only, and assuming initial conditions of supplying only peak-load energy, the estimated cost per kilowatt-hour then will approach the maximum rate imposed.

Beyond this, there may be some problematical capital expenses only hinted at in our discussion, as where it was noted that the private company had attractive rates for off-peak power and that such business would have to be fought for by the municipal department. Such a struggle means investment in "going concern," which the municipality must make—willingly or not. The company now possesses the business and presumably has capitalized a certain cost of building it up. The new plant comes into the field unencumbered by such a capital burden, but also handicapped by lack of its opponent's favorable business; to improve its load the city plant must assume the expense of building up new business. A plant like this cannot altogether work on a basis of original cost, without burdening the taxpayers.

On the ethical side, of course, if a company has really been denied the privilege of amortizing dead capital expenditures and cost of intangibles, it does not seem common justice to let a competitor step into a fully developed industry. But in the absence of specific denial of the amortization privilege, failure to secure the needed sums out of earnings would seem to be chargeable against the ability of the managers. If a company has not been able to secure the desired amortization fund out of its earnings and still to make attractive prices, but hopes to be able to recover sooner or later, then it should frankly state its case to the public before or as soon as destructive competition begins to loom up.—ED.]

The 200,000-Hp. Development of the Mt. Shasta Power Corporation on the Pitt River, California

Brief mention was made in ENGINEERING NEWS, July 16, 1914 of a seven-mile tunnel being built by this company as a part of a hydro-electric power project. The following information has since been secured on the other features of this development.

FIG. 1. GENERAL LOCATION OF PITT RIVER DEVELOPMENT, RELATIVE TO SACRAMENTO VALLEY AND COAST CITIES

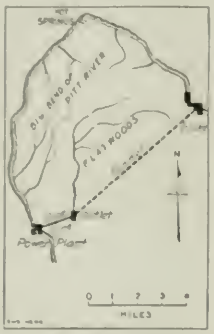


FIG. 2. PRELIMINARY PLAN OF RIVER DEVELOPMENT

The corporation is not given in current lists of public utilities, etc., so that its status has remained hidden to many. It is interesting to note, therefore, that the company was incorporated in California in 1912 by C. L. [illegible], Jos. Haber, Jr., A. M. Moore, and Edgar [illegible], Lilienthal, McKinstry & Raymond being the attorneys. The capitalization was then placed at $10,-000,000.

The location of this proposed plant is on the Pitt River near Redding at the head of the Sacramento valley. Its

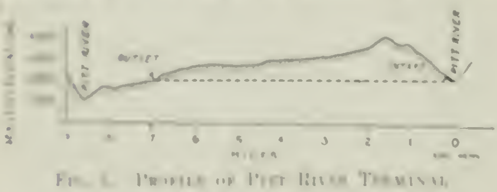

FIG. 3. PROFILE OF PITT RIVER TERMINAL

[illegible] purposes, it is planning to furnish power for the mining [illegible] railroads to the north, and to the [illegible] industries of the cities and towns of the Sacramento Valley as far south as Oakland, a transmission distance of [illegible] miles.

The plan of development involves the construction of a tunnel [illegible] ft. long. From the tunnel outlet the water may be conveyed in a pipe or open conduit and pipe to the power house, a total distance from the intake portal of a little less than one mile. The static head is [illegible] ft. and the minimum discharge of the river taken from daily gage readings for the past six years is [illegible] sec.ft. In 1902 the flow was 2560 sec.ft.; in 1903 it was 2850 sec.ft. The power in the minimum flow is 262,000 hp., and it would require only 76.5% efficiency of turbines and generators to secure 200,000 hp. at the feeders; with ordinary transmission losses, 175,000 hp. should be the possible delivery to San Francisco. The designed tunnel section, 16x19 ft., will carry more than the minimum flow.

Water rights were located in 1906, since when extensive surveys have been made, lands purchased, and riparian rights acquired covering practically the entire length of the river between the intake portal and power house, a distance of about 20 miles. Work has been started on a 7x8-ft. heading at each end of the tunnel and a little more than one mile of these headings has been driven. Air compressors, ventilating fans, electric lights, etc., operated by water power have been installed at each end of the tunnel. The company with W. A. Cooper, San Francisco, as Chief Engineer, is pushing its construction and arranging plans to deliver power to meet certain market demands which it expects.

In accordance with present designs, the Pitt River development promises to be one of the few 200,000-hp. plants; it should show the shortest conduit per horsepower capacity in California, the longest tunnel in this country and the largest in the world for water power.

An Automatic Petroleum-Tank Fire Extinguisher*

An automatic tank-fire extinguishing equipment consisting of standpipes placed around and connected to the storage tank, as shown in Fig. 1, was recently tested with satisfactory results, at the Bayonne, N. J., refinery of the Standard Oil Co.

The first test was run on July 22 in connection with a roofed tank 40 ft. in diameter. The fire apparatus consisted of four standpipes 30 in. in diameter, the same

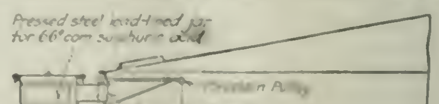

FIG. 1. ERWIN FIRE EXTINGUISHER FOR OIL STORAGE TANKS

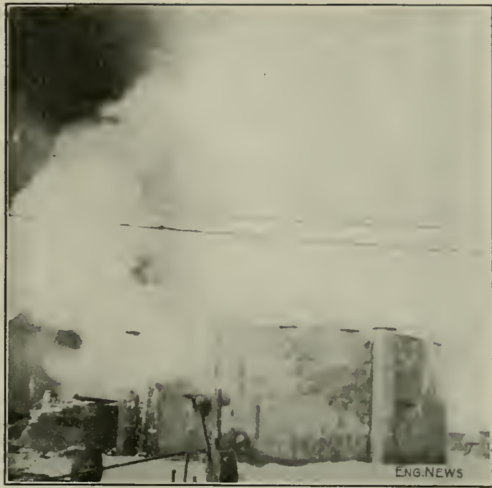
height as the tank, arranged outside and against the tank at intervals of 90 deg. There was a direct outlet into the tank from the standpipe, about 12 in. wide by 8 in.

*Information furnished by Charles S. Swartz, General Manager, Erwin Co., Milwaukee, Wis.

Fire at its height



One minute 30 seconds later

FIGS. 2-3. FIRE EXTINGUISHING TESTS AT BAYONNE, N. J., JULY 22.

deep, at the top of the tank. These standpipes contained about 1 gal. of a solution of sodium carbonate and soap bark per square foot of oil surface. Lead-lined sulphuric acid containers were suspended from the top of the standpipes, and connected to a phosphor-bronze cable containing standard fusible links, controlled by a series of triggers. The cable and fusible links were arranged to permit frequent inspection.

In the test, water was admitted to the tank to within 3 ft. of the top; 3000 gal. of Mexican crude oil and some naphtha were floated upon the water, and a torch applied. When the fuses melted, the acid dropped into the chemical solution in the standpipe and the resulting foam started instantly into the tank through the opening. The fire was automatically extinguished in 9 sec. by a 14-in. layer of foam.

On July 24, another test was run, in which the fire was permitted to gain headway (Fig. 2). The roof and automatic devices were removed, and the standpipes arranged to operate by hand on a 75-ft. cable, so that the acid could be released at will. The water in the tank was lowered 6 ft. It was thought by some that the foam in issuing from the discharge opening would be destroyed to a certain extent, and that its swift delivery across the surface of the oil would be impossible. On the water in the tank, 3000 gal. of Mexican crude oil and 100 gal. of gasoline were floated and ignited. The fire was permitted to rage for five minutes, when one of the standpipes was operated. It made little impression. The remaining standpipes were released 30 sec. later and the fire was extinguished in one minute (Fig. 3).

FIG. 4. APPEARANCE OF FOAM AFTER SEVERE FIRE

A Visible Interstate Boundary Line—As probably almost every reader knows, the city of Texarkana is on the interstate boundary of Texas and Arkansas. An enterprising local newspaper suggests making use of this unusual feature as an advertising asset; it says:

This state line we have running through our city, instead of being a source of contention and misunderstanding, if properly appreciated could be made the basis of a business condition which few other cities of America have the privilege of using.

Some time ago it was suggested that as an advertising feature, it would be a good idea to lay a row or two of white brick up the state line and across Broad street to indicate to visitors just where the line really is located.

In this connection it was suggested by one of the members of the improvement committee this morning that when State Line Ave. is paved, it being understood that the character of paving on both sides would be in conformity, it would be a good idea if a line of different color could be placed in the center of the street on the state line, and extending from the depot to the postoffice.

This recalls the aerial voyage of Tom Sawyer and Huck Finn; after travelling all night there was some question whether they had passed over the State of Illinois, but the point was settled by the green landscape; they hadn't made the Indiana line yet because in all the geographies they ever studied Indiana was pink, and Illinois green.

Progress of Work on the New Buildings of the Massachusetts Institute of Technology

At the time the accompanying photograph was taken, July 31, the concrete foundations of the new buildings of the Massachusetts Institute of Technology in Cambridge, Mass.,* were practically all in place. The amount of this work may be gauged when it is remembered that the sum of the sites of the various buildings is between 2500 and 3000 ft. For these foundations, piles have been driven for all outside and interior walls and for piers. A considerable part of the concrete work for the walls to the level of the first floor was also in place.

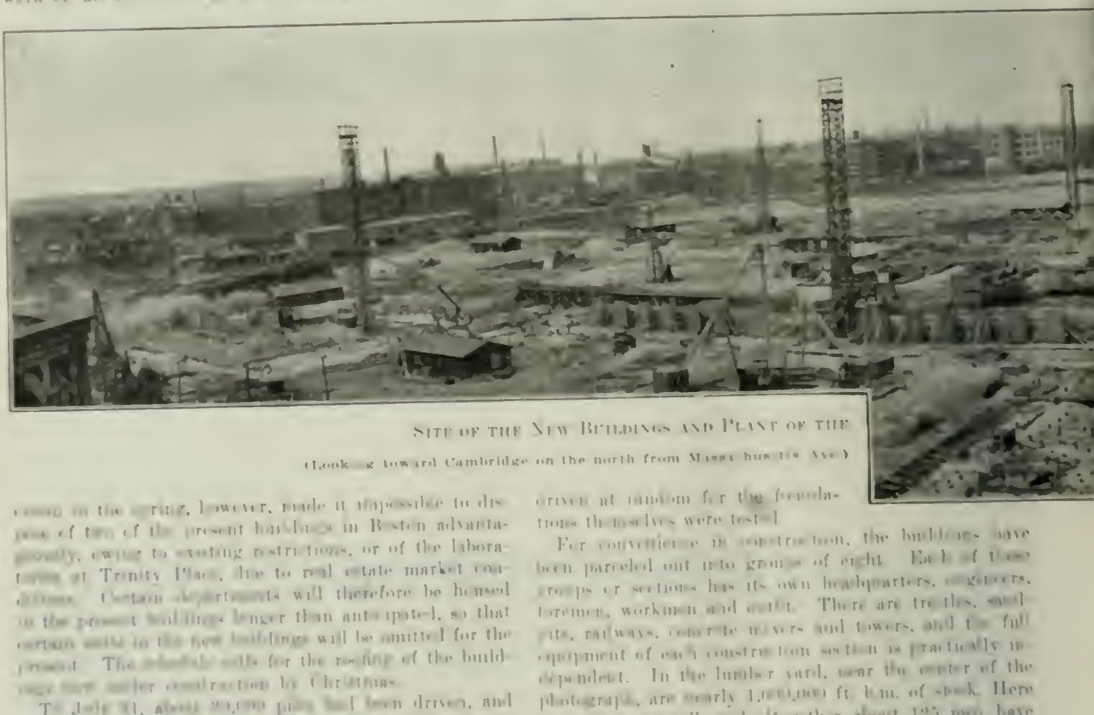
Work was held up for a time by changes in the original scheme of construction, which was to carry on the work on all the buildings simultaneously. A court decision in the spring, however, made it impossible to dispose of two of the present buildings in Boston advantageously, owing to existing restrictions, or of the laboratories at Trinity Place, due to real estate market conditions. Certain departments will therefore be housed in the present buildings longer than anticipated, so that certain units in the new buildings will be omitted for the present. The schedule calls for the roofing of the buildings now under construction by Christmas.

To July 31, about 20,000 piles had been driven, and 3000 more are to be placed for the library-building foundations. About half of all the piles are 50-ft. hard pine and the other half are oak, 35 ft. long. Each pile is designed to carry a load of 10 tons.

The new buildings are on made land, and preliminary to construction, extensive tests and investigations were carried out to determine its bearing power. The determination of the character of the subsoil was undertaken by Prof. W. O. Crosby, a graduate of the Institute, who was consulting geologist for the Catskill aqueduct, New York. He made a systematic subsoil survey by means of 64 borings. Prof. Crosby's report shows that in the vicinity of the present land a tongue of gravel extended into an old glacial lake. The Institute grounds are largely clear of peat, which was apparently extensively formed on neighboring areas.

Incidental to the work of construction, the contractor, the Stone & Webster Engineering Corporation, also made a series of investigations, including about 73 additional borings to a depth of 80 ft. Besides these about a dozen other borings were made in the vicinity, outside of the Institute grounds. At present, 12 other borings are being made within the foundation lines for the new library building, to determine the areas of hard driving.

Besides soil borings a series of tests were made on the bearing power of piles, 68 tests in all. Ten concrete piles were tested to loads up to 100 tons each. Wood piles were tested up to loads of 15 tons each. Only wood piles were adopted for construction. Some of the piles are driven to 55 ft., but the average depth of the glacial drift is from 12 to 30 ft. In addition to the tests already noted, 8 piles driven at random for the foundations themselves were tested.



SITE OF THE NEW BUILDINGS AND PLANT OF THE

(Looking toward Cambridge on the north from Massachusetts Ave.)

For convenience in construction, the buildings have been parceled out into groups of eight. Each of these groups or sections has its own headquarters, engineers, foremen, workmen and outfit. There are trestles, sand pits, railways, concrete mixers and towers, and the full equipment of each construction section is practically independent. In the lumber yard, near the center of the photograph, are nearly 1,000,000 ft. b.m. of stock. Here there is a sawmill, and altogether about 125 men have been kept busy making forms for concrete work. A mile of railway track makes every facade approachable for freight.

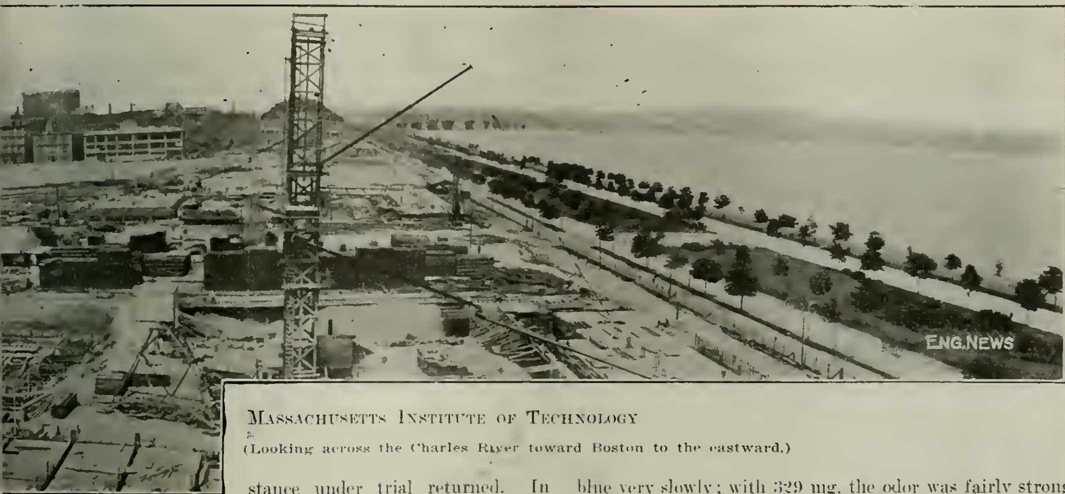
*For a description of the plans and scheme see "Engineering News," Nov. 20, 1913, pp. [illegible]

Further Studies of the Deodorizing Effects of Ozone

The published reports of Drs. F. O. Jordan and A. J. Carlson (See ENGINEERING NEWS, Nov. 27, 1913), which were unfavorable to the general use of ozone in ventilation and therapeutics, naturally raised a storm of criticism from more or less interested parties. Some of this was mere assertion, but there has been also the very desirable result of a careful scientific scrutiny of

the procedure of the investigators named. One of the most interesting and illuminating counter-investigations is that made by J. C. Olsen and W. H. Ulrich, of the Brooklyn Polytechnic Institute and reported in a paper at the Troy meeting of the American Institute of Chemical Engineers, June 19, 1914.

The original investigators (Jordon and Carlson) experimented with a considerable number of odorous substances and reached the broad conclusion that ozone masked but did not destroy odor. Their method of procedure consisted of exposing the substance, giving off odor until the smell was noticed in a small closed room. Then a commercial ozone generator was operated until a strong counter-odor was produced. Observations were made from time to time of the smell in the room and it was observed in many cases that the ozone odor gradually disappeared and that the odor of the peculiar substance under trial returned. In some cases the ozone was introduced again and the observations repeated.



MASSACHUSETTS INSTITUTE OF TECHNOLOGY

(Looking across the Charles River toward Boston to the eastward.)

Olsen and Ulrich criticized the earlier investigators for apparently neglecting to consider that any destruction to be found would be an oxidizing process and one in which a definite amount of oxygen would be required to oxidize a definite amount of odor substance, and for not knowing whether or not they had supplied sufficient ozone at any time to oxidize more than a fraction of the odor substance in the air. The counter-investigation was made to consider these factors.

They took up first hydrogen sulphide, 34 parts of which would require 48 parts of ozone for oxidation. They found, with 7.6 mg. of hydrogen sulphide liberated per cubic meter of room atmosphere, that no odor was noted and lead-acetate paper turned brown very slowly. A faint odor was detected with 15 mg., a distinct odor with 61, and a strong odor with 211. In comparison with this they found that the odor of ozone was marked when there was present only 1 mg. per cu.m., the limit of observation being 0.1 mg. A concentration of 1 mg. ozone would have masked the odor of 61 mg. hydrogen sulphide and by the action of the ozone less than 1 mg. of the 61 would be oxidized—leaving sufficient hydrogen sulphide unattacked to give the characteristic odor.

Atmospheres of hydrogen sulphide and ozone were combined with respective concentrations of 25 and 35.6 mg. per liter, under which conditions there should be just enough ozone to oxidize the hydrogen sulphide. The ozone odor was very pronounced at first, but after it had disappeared there was no odor of hydrogen sulphide. A slight acidity of the residual atmosphere was detected on exposure of blue litmus paper. Some oxidation was reported in check trials with atmospheric oxygen.

Observations were also made with ammonia; of this, one part would be oxidized by about four parts of ozone. With 10 mg. per cu.m. no characteristic odor was noted and no action was found upon litmus paper. With 21 mg. there was very faint odor and reaction; with 82 mg. the odor was quite distinct and the red litmus turned blue very slowly; with 329 mg. the odor was fairly strong and the litmus turned blue slowly; with 1000 mg. the odor was strong and reaction rapid. Atmospheres of ozone and ammonia were mixed in concentrations of 35.6 and 125 mg. per cu.m., respectively. As the action was slow, 24 hr. was allowed for it. Some oxidation was found, though not the destruction of the full 8.5 mg. theoretically expected. (Foreign investigators have reported finding no reaction between ammonia and ozone.)

Studies were made with oil of cloves. The amount of ozone necessary to oxidize the vapor of oil of cloves could not be calculated, but the investigators believed that it would require several times more than equal weight. It was found that as little as 66 mg. oil evaporated per cu.m. of atmosphere resulted in a strong smell. On mixing the oil-of-cloves atmosphere and ozone, with concentrations of 36.6 and 33 mg. per cu.m., respectively, it was found that first there was a distinct smell of ozone, but this gradually disappeared and was replaced by a sweet odor which had no resemblance to the original cloves. This was interpreted as meaning that the strong smelling constituents were partially oxidized. The reaction, however, was not entirely regular. The formation of the sweet aromatic residue was repeatedly observed, though at times the original odor of cloves persisted.

The First Large Ship Through the Panama Canal

The official opening of the Panama Canal to the commerce of the world took place Saturday, Aug. 15, with very little pomp or ceremony.

On Aug. 7, the "Cristobal," a 9600-ton steamship of the Panama R.R. Co., made the passage from the Atlantic to the Pacific in $11\frac{1}{2}$ hr., and returning in $8\frac{1}{2}$ hr.

The "Cristobal" is a steel twin-screw steamship of 9606 gross tons and 6195 net tons burden. It is $489\frac{1}{2}$ ft. long and 58 ft. in beam, drawing 25 ft. of water.

The passage was made without accident other than some minor difficulties with the towing locomotives.

The Steamship "Cristobal" in Culebra Cut, Aug. 7, 1914; 9600-Ton Steamer, $489\frac{1}{2}$ Ft. Long, 56 Ft. Beam

Tugs, barges and dredges had been passed through the canal before, but this was the first large steamship.

On Aug. 15, the official party, including Col. George W. Goethals, Governor of the Canal Zone, and about 75 officers made the trip from the Atlantic to the Pacific in the "Ancon," of the Panama Railroad Co., a sister ship of the "Cristobal." The passage of the Gatun locks was made in 70 min., and the whole trip took 9 hr.

The Canal is now open to all vessels not drawing more than 30 ft. of water; this includes war vessels of the European nations now at war, but no warship of a belligerent nation may remain longer than 24 hr. within the limits of the canal.

The principal work remaining to be done is the deepening and widening of the channel through Culebra cut.

NEWS NOTES

An Old Wooden Bridge Collapsed just after an automobile had passed over it, at Pickering, Ont., on Aug. 6. The structure was called Maxwell's Bridge. Its span is given as 100 feet.

A 50-Hp. Boiler Exploded at a shop in Unicorn, Penn., at 10:30 p.m., Aug. 6. It was lifted from its brick setting and hurled through a wall into a field across the road, a distance of about 130 ft. The crown sheet was thrown about 50 ft. away. The brick stack and the rear of the shop were wrecked. Press reports state that the fire had been banked as usual that night, at which time the steam pressure was about 30 lb.

A Gate Accident on the Welland Canal—An unusual accident occurred at Lock 12 of the Welland Canal, on Aug. 9, which stopped transportation for about 24 hours, according to the acting superintending engineer, at St. Catharines, Ont. The steamer "Winona," of the Montreal Transportation Co., upbound to Port Colborne for grain, had just entered the lock; one footgate had been closed and the other was about to be closed when the canal linemen, who are hired by vessels navigating the canal, opened wide the valves in the upper gates. The strong current was stopped by the steamer and crashed against the closed gate, [illegible] with it [illegible]. This sudden [illegible] caused a surge in the lock, which carried the vessel [illegible] against the headgates [illegible]. The rush of water from Lock-12 reach carried them [illegible] away and [illegible] the steamer into the reach below, [illegible] the footgates. The canal banks at the head of lock 11 were badly [illegible]. The ship was not damaged. Four piles were installed before traffic was resumed. The damages were estimated at $5000.

The Greater Winnipeg Water Supply project, for bringing water from Shoal Lake, 96 miles [illegible] of the city, is [illegible]. The entire right-of-way for the aqueduct, 97

miles, has been cleared of timber and the work for its drainage is proceeding rapidly, while about 40 miles of grading has been done for the construction railway over the route and about 20 miles of track have been laid. Plans and specifications have been completed for the construction of 85 miles of the gravity-flow concrete aqueduct, which will extend from Indian Bay to the storage reservoir site southeast of Transcona, a few miles from Winnipeg. Pipe lines will run from this reservoir to the city. Bids for the aqueduct work will be opened Sept. 19. The total cost of the project is estimated at $13,000,000, and the construction work will occupy probably five years. The project is under the direction of the Greater Winnipeg Water District. S. H. Reynolds is Chairman of the Commissioners; W. G. Chase is Chief Engineer; James H. Fuertes, New York City, is Consulting Engineer. An outline of the project as recommended by a board of consulting engineers consisting of Rudolph Hering, Frederic P. Stearns and James H. Fuertes was printed in "Engineering News" of Sept. 25, 1913.

A Telephone Block System is to be installed by the Southern Ry. on the Atlantic Division, between Macon, Ga., and Ooltewah Junction, Tenn., 225 miles. The present telegraph block system consists of one telegraph wire. The telephone block is to consist of two wires, this arrangement being effected by utilizing the present telegraph block wire and a telegraph message circuit. Each office on this block circuit will be equipped with two bells, one for the north block and one for the south block, with the telephone so installed that it can be connected with either set. The lines will be so arranged at the offices that when a block office is closed the line can be cut through. The wires used for the telephone block will be used also for a telegraph circuit from Atlanta to Macon, and for another circuit from Atlanta to Ooltewah Jct., into Chattanooga, Tenn. In order to take care of the heavy Florida traffic last winter, the telephone block system was put in operation between Macon and Jesup, and was found so satisfactory that it has now been decided to extend the system. The management has also authorized the installation of a Simplex telephone block circuit between Monroe, Va., and Greensboro, N. C., 120 miles. The work is under the direction of W. H. Potter, Superintendent of Telegraph.

PERSONALS

Mr. R. C. Harris has been appointed Resident Engineer of the Alberta division of the Canadian Pacific Ry., at Calgary, Alta.

Mr. J. T. Brown has been appointed Resident Engineer and Superintendent of Bridges and Buildings of the Canadian Pacific Ry., Alberta division, at Cranbrook, B. C.

Mr. George Stahl has been appointed City Engineer of Milwaukee, Wis., succeeding Mr. J. A. Mesiroff, who resigned some time ago to become Consulting Engineer of the Western Engineering & Construction Co., of Milwaukee.

Mr. Donald F. McLeod, Assoc. M. Am. Soc. C. E., former City Engineer of Saranac Lake, N. Y., recently of New Glasgow, N. S., Canada, has been made City Manager of Lakeland, Fla.

Mr. A. G. Kinyon, formerly Locomotive Fuel Engineer of the Clinchfield Fuel Co., Spartansburg, S. C., has been appointed Superintendent of Locomotive Operation of the Seaboard Air Line Ry., with headquarters at Portsmouth, Va.

Mr. H. J. Saunders, Assoc. M. Am. Soc. C. E., formerly Consulting Engineer with offices at Valier, Mont., has been appointed Office Engineer, Division of Valuation, Interstate Commerce Commission, Western District, with headquarters at San Francisco, Calif.

Mr. Arnold Pfau, M. Am. Soc. M. E., Consulting Engineer of the Allis-Chalmers Manufacturing Co., Milwaukee, Wis., one of the foremost designers of hydraulic turbines, is being detained in Switzerland, where he went to visit his old home. Mr. Pfau is a native of Switzerland and is eligible for army service there.

Mr. W. E. Thomas, Assoc. M. Am. Soc. C. E., former Resident Engineer of the Flushing improvement of the Long Island R.R., New York City, is now District Manager at Charlotte, N. C., for Weston & Brooker, Inc., of Columbia, S. C., designers and builders of sanitary sewerage systems and sewage disposal works.

Mr. Frederic A. Delano, M. Am. Soc. C. E., whose appointment as a member of the Federal Reserve Board was noted in our columns of last week, has resigned as President of the Chicago, Indianapolis & Louisville Ry., to accept the appointment. He is to be Vice-Governor of the Board and will have headquarters at Washington, D. C.

Mr. R. W. Creuzbaur, M. Am. Soc. C. E., Consulting Engineer, New York City, has been appointed Engineer of the City of Elizabeth, N. J., to supervise the city's part in the grade-crossing elimination and improvement work of the Pennsylvania R.R. and Central R.R. of New Jersey in that city. Mr. Creuzbaur will devote only a portion of his time to this work.

Mr. King Lo, a resident of Canton, China, is studying highway work as an official representative of the Chinese Government in the main office of the New York State Highway Department, Albany, N. Y. Mr. Lo is a graduate of Rensselaer Polytechnic Institute. His education and practical experience are at the expense of the Home Department of the Chinese Republic.

Mr. Roger L. Morrison, Jun. Am. Soc. C. E., of the road department of the United Gas Improvement Co., of Philadelphia, Penn., has been appointed Professor of highway engineering at the Agricultural and Mechanical College of Texas, succeeding Mr. R. J. Potts, resigned, as noted in our personal columns of July 9. Mr. Morrison is a graduate of the University of Illinois, class of 1911, and of the Columbia University course in highway engineering.

Mr. E. J. McCaustland, M. Am. Soc. C. E., formerly Professor of municipal and highway engineering at the University of Washington, Seattle, Wash., President and Sanitary Engineer of the Washington State Board of Health, has been appointed Dean of the Faculty of Engineering at the University of Missouri, succeeding Mr. Howard B. Shaw, who has resigned to become Chief Engineer of the Missouri State Public Service Commission, as noted elsewhere.

Mr. Howard B. Shaw, Assoc. Am. Inst. E. E., formerly Professor of electrical engineering and Dean of the Faculty of Engineering at the University of Missouri, has been appointed Chief Engineer of the Missouri State Public Service Commission. Mr. Shaw is a graduate in civil engineering of the University of North Carolina, class of 1890, and received the degree of A. M. at Harvard University in 1894. For two years, he was an Assistant in the electrical engineering laboratory of the Lawrence Scientific School, Harvard University, and since 1896 he has been connected with the faculty of the University of Missouri.

Mr. George W. Boschke, who resigned as Chief Engineer of the Oregon-Washington R.R. & Navigation Co. on May 1, has been appointed Engineer in charge of the San Francisco, Calif., offices of Twohy Bros., of Portland, Ore., railway contractors. Mr. Boschke began his railway engineering experience in 1886 with the Southern Pacific Co. He had charge of the construction of various lines in Texas, and in addition to his connection with the Southern Pacific Co., was Engineer in charge of construction of the Galveston, Tex., seawall. He was Chief Engineer of the Oregon-Washington R.R. & Navigation Co. from 1905 until May 1, 1914.

Mr. David B. Steinman, Jun. Am. Soc. C. E., former Professor of civil engineering at the University of Idaho, has been appointed Special Assistant Engineer of the New York Connecting R.R. Hell Gate Bridge, New York City, to temporarily succeed Mr. O. H. Ammann, M. Am. Soc. C. E., who has returned to his native country of Switzerland to serve in the army, as noted in our issue of last week. Mr. Steinman is a graduate in civil engineering of Columbia University, class of 1909, and received a Ph. D. degree there in 1911. For a short time he was connected with engineering staffs of the Board of Water Supply and the Public Service Commission in New York City, and since 1910 has been Professor of civil engineering at the University of Idaho.

Col. Merritt H. Smith, M. Am. Soc. C. E., whose appointment as Chief Engineer of the Department of Water Supply, Gas and Electricity was noted in our personal columns of July 9, was the guest of honor of 700 enthusiastic engineer and contractor friends at a dinner at the Biltmore Hotel, New York City, Aug. 13. Although the weather was unusually hot, the hotel accommodations were taxed to the utmost. The guests included Mayor John Purroy Mitchel, all three members of the Board of Water Supply, the Borough President of Manhattan, and other prominent city officers. Mr. J. Waldo Smith, Chief Engineer of the Board of Water Supply, was toastmaster. Many old-time members of the Board of Water Supply engineering staff, now prominent in the public works of other cities, journeyed to New York to attend; and the meeting was more of the nature of a college alumni feast than anything else. Col. Smith has been one of the most popular members of the engineering corps of the Board of Water Supply, and has done much to inspire the feeling of good fellowship and the esprit de corps for which this engineering staff has been famous.

OBITUARY

John P. Holland, famous as the inventor of the Holland submarine boat, died at his home in Newark, N. J., Aug. 12. He was born in Paterson, N. J., 73 years ago. His first submarine boat was built in 1877 and launched in the Passaic River in 1878.

Charles T. Healy, a well known land surveyor and civil engineer of Los Angeles, Calif., died at his home in that city Aug. 3, aged 85 years. He went to California in the pioneer days, 60 years ago, and for many years was engaged in land surveying and civil engineering. He is said to have surveyed many of the original plots in Los Angeles and Long Beach.

Joseph J. Cox, a prominent Kansas contractor, died Aug. 4 at his home in Lawrence, Kan., after an illness of more than six months. He was born in Seymour, Ind., Oct. 6, 1853. In 1870 he moved with his parents to a farm near Lawrence, Kan., where he was married in 1872. Subsequently he went into contracting and during the long course of his business life completed many important structures.

Charles Webster Danforth, New York Manager of the Pittsburgh Steel & Iron Co., Pittsburgh, Penn., died Aug. 9, in the Grand Central Station, New York City, while about to start on a vacation. He was born in New Haven, Conn., and was a graduate of Sheffield Scientific School, Yale University, class of 1896, in civil engineering. He was formerly with the American Bridge Co., of Pittsburgh.

Donald M. Philbin, recently General Manager of the Great Northern ore properties in Minnesota and formerly General Superintendent of the Lake District of the Great Northern Ry., died Aug. 6, at his home in Duluth, Minn., after an illness of over a year. He was born in Montreal, Que., in 1857, and at 17 years of age began his railway experience as a clerk in the construction department of the Chicago & Northwestern Ry. From 1877 to 1886 he was in charge of the ore docks of the Chicago & Northwestern Ry. at Escanaba, Mich., and for two years in charge of the ore docks of the Milwaukee, Lake Shore & Western R.R. at Ashland, Wis. In 1890 he was appointed Division Superintendent of the Duluth, South Shore & Atlantic Ry., and from 1893 to 1896 was General Manager of the Duluth, Missabe & Northern Ry. Subsequently he was an operating officer of lines which became a part of the Great Northern Ry.

Edward C. Johnson, recently Commissioner of Public Works of Los Angeles, Calif., died Aug. 2, at his old home in Belfast, Maine. He was a graduate of the Massachusetts Institute of Technology, and for several years was on United States Government Survey work in the West. He first came into public notice in Los Angeles during the investigation of the Los Angeles Aqueduct, when he was appointed a member of the investigating committee as an engineering expert. Following his work here he was appointed a member of the Harbor Commission and upon the resignation of Gen. Adna R. Chaffee from the Board of Public Works, a few years ago, Mr. Johnson was appointed to succeed him, and as such had charge of the aqueduct work. For the last eight months he had been in failing health, and some weeks ago returned to his home in Maine and resigned his office in Los Angeles shortly afterward. Mr. Johnson is survived by a widow and a daughter eight years old.

Alfred P. Trautwein, M. Am. Soc. M. E., Vice-President of the American Welding Co., Carbondale, Penn., died Aug. 5 at his home in Scranton, Penn. He was born in New York City in [illegible] and graduated in mechanical engineering at Stevens Institute of Technology in 1876. He went to Carbondale in [illegible] as Consulting Engineer of the Hendrick Manufacturing Co. Later he organized and was President of the Carbondale Machine Co. He also aided in organizing the Carbondale Chemical Co., the Carbondale Instrument Co., the American Welding Co., and numerous other enterprises. He was a member of the Engineers' Club of Philadelphia and a Past-President of the Scranton Engineers' Club. He was also a Past-President of the Engineering Society of Northeastern Pennsylvania. Mr. Trautwein was a trustee of Stevens Institute and a director and trustee of many other business, educational and philanthropic institutions. He is survived by a widow and four daughters.

[illegible] Oestreich, M. Am. Soc. C. E., Senior Assistant Division Engineer, Public Service Commission, First District, New York, died Aug. 11 at Atlantic City, N. J., aged [illegible] years. He was born in New York City and attended the public schools and New York University. He joined the engineering staff of the old Rapid Transit Commission as Assistant Engineer at the beginning of the New York City subway work in 1900, and ever since then continued in the employ of the city. He had charge of construction of the section of the present subways on Lafayette St. and 4th Ave., between Great Jones and 19th St. Later he had charge of important construction on the Centre St. loop. Recently he had been in charge of sections of the Fourth Ave. subway in Brooklyn. Mr. Oestreich was married on June 10, 1914, to Miss Stella B. Eccles, of Trenton, N. J., and went to Atlantic City on his honeymoon. While there he contracted blood poisoning from a scratch on his face. He was a prominent member of the Brooklyn Engineers' Club and of the Municipal Engineers of the City of New York.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN ASSOCIATION OF RAILROAD SUPERINTENDENTS.
Aug. 20-21. Annual meeting in New York City. Secy., E. H. Harman, Room 101, Union Station, St. Louis, Mo.

AMERICAN PEAT SOCIETY.
Aug. 20-22. Annual meeting at Duluth, Minn. Secy., Julius Bordollo, 17 Battery Place, New York City.

AMERICAN BOILER MANUFACTURERS' ASSOCIATION.
Sept. 1-3. Annual convention in New York City. Secy., J. D. Farasey, E. 37th St., and Erie Ry., Cleveland, Ohio.

AMERICAN MINE SAFETY ASSOCIATION.
Sept. 7-10. Annual meeting in New York City. Secy., H. M. Wilson, Bureau of Mines, Pittsburgh, Penn.

AMERICAN FOUNDRYMEN'S ASSOCIATION.
Sept. 7-11. Annual meeting at Chicago, Ill. Secy., A. P. Backert, Cleveland, Ohio.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.
Sept. 9-11. Annual convention at Buffalo, N. Y. Secy., Will P. Blair, 832 B. of L. E. building, Cleveland, Ohio.

NATIONAL ASSOCIATION OF PORT AUTHORITIES.
Sept. 8-10. Annual convention in Baltimore, Md. Secy., Wm. Joshua Barney, 29 Broadway, New York City.

ROADMASTERS AND MAINTENANCE OF WAY ASSOCIATION OF AMERICA.
Sept. 8-11. Annual meeting at Chicago, Ill. Secy., L. C. Ryan, Sterling, Ill.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION.
Sept. 8-11. Annual convention in Nashville, Tenn. Secy., A. P. Dane, Reading, Mass.

NEW ENGLAND WATER-WORKS ASSOCIATION.
Sept. 9-11. Annual convention in Boston, Mass. Secy., Willard Kent, Narragansett Pier, R. I.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.
Sept. 15-18. Convention in Atlantic City, N. J. Secy., Clayton W. Pike, Electrical Bureau, Philadelphia, Penn.

ILLUMINATING ENGINEERING SOCIETY.
Sept. 21-25. Annual convention in Cleveland, Ohio. Secy., Joseph D. Israel, 29 W. 39th St., New York City.

RAILWAY SIGNAL ASSOCIATION.
Sept. 22-24. Annual convention in Bluff Point, N. Y. Secy., C. C. Rosenberg, Times Building, Bethlehem, Penn.

ATLANTIC DEEPER WATERWAYS ASSOCIATION.
Sept. 23-26. Annual convention at New York. Secy., Addison Burke, Philadelphia, Penn.

American Boiler Manufacturers' Association—The 26th annual convention will open at 10 a.m., Sept. 1, at the Waldorf-Astoria Hotel, and close with an executive session Friday morning, Sept. 4. There will be four business sessions and probably a trip to Coney Island Wednesday evening. The annual banquet will be held at 7:30 p.m., Sept. 3. The secretary is J. D. Farasey, East 37th St. and Erie Ry., Cleveland, Ohio.

Illuminating Engineering Society—Among the papers to be presented at the annual meeting in Cleveland, Ohio, Sept. 21-26, are the following: "Factory Lighting," Hogue and Dicker; "Planning for Daylight and Sunlight in Buildings," Marks and Woodwell; "The Effects of Room Dimensions on Efficiency of Lighting Systems," Ward Harrison; "Illumination of Light Shafts," S. H. Sharp; "The Locomotive Headlight," J. L. Minick; "Physiological Effect of Light on the Body," E. C. Titus.

American Foundrymen's Association—At the annual meeting to be held Sept. 7-11, at Chicago, the following papers will be presented: "The Second-Story Foundry," G. K. Hooper, Detroit; "Molding Sand Tests," Dr. Richard Moldenke, Watchung, N. J.; "Test of Malleable Cast Iron," Enrique Touceda, Albany, N. Y.; "The Electric Furnace in the Steel Foundry," W. L. Morrison, Welland, Ont.; "Some Defects in Steel Castings and Remedies for Them," John Howe Hall. The Secretary is A. P. Backert, Cleveland, Ohio.

Engineering Literature

CONTENTS

CORRESPONDENCE

Continuation of Title-Page Date Discussion

Sir—I have read with interest Dr. C. T. Hutchinson's letter published in your issue of July 16, in which he denounces the use of the term "Second Edition Revised" to designate the current issue of my book on "Electric Power Conductors."

The book under consideration has 324 pages, exclusive of the index. In anticipation of the exhaustion of the first edition, 14 new pages of electrotype were made and 29 pages had their electrotype altered or corrected, a total of 43 pages, or 13⅓% of the entire number of pages in the book. This percentage reduces to 12 if the 4-page rubber specification is omitted. I said in the preface that "nearly 10%" of the pages had been more or less altered. It will thus be observed that I understated the proportion rather than overstated it as intimated by Dr. Hutchinson. Nevertheless, I do not think that the minor alterations would have justified calling the book a second edition, but I do believe that the changes on about 20 of the pages were ample warrant for doing so. The book, altered as described above, was issued as a second edition at the suggestion of the publisher and with my approval. There was ample respectable precedent for this action and none that I know for any other course.

If the book had been sold as a reprint of the first edition, a great deal of confusion would have resulted in making references. For example, if an engineer were to order wire insulated in accordance with the specification in the first edition of "Electric Power Conductors," and if both editions were known as first editions, the manufacturer would be at a loss to know what to supply, and the purchaser would not be sure of getting what he wanted.

I am in sympathy with Dr. Hutchinson in deploring the uncertainty incident upon the use of the word "edition." The whole trouble is that the word "edition," and its various qualifying terms, do not mean the same thing to different people. Thus, it is evident that to Dr. Hutchinson, the term "Second Edition Revised" means what the publishers usually call "Entirely Rewritten."

I believe that Dr. Hutchinson could have employed his talent to better advantage if he had taken the trouble to write a constructive letter suggesting a series of terms to describe the different varieties of revisions of a book. If such a letter had been written and followed up by an effort to have its recommendations adopted by the publishers as standard, Dr. Hutchinson would have rendered a distinct service.

Wm. A. Del Mar.

70 East 45th St., New York City, July 30, 1914.

REVIEWS AND NOTES

A New Edition of Whipple's Microscopy of Drinking Water

Reviewed by Desmond FitzGerald*

THE MICROSCOPY OF DRINKING WATER—By George Chandler Whipple, Gordon McKay Professor of Sanitary Engineering, Harvard University and the Massachusetts Institute of Technology. With a Chapter on "The Use of the Microscope," by John W. M. Bunker. Third edition, rewritten and enlarged. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. xxi + 409; 73 illustrations; 25 plates. $4, net.

More than one water-works engineer will figuratively toss his hat into the air and shout "Hurrah!" at the appearance of a third edition of Whipple's book; firstly, because the book has proved itself already of real practical assistance in water-supply practice; and secondly, because this new edition is a demonstration of the popularity of a good scientific treatise on the microscopy of drinking water; in fact, the day is fast approaching when no manager of a water-supply system can afford to be without it, and the day is already here when libraries which are looking around for standard treatises, welcome it to their shelves.

In addition to pointing out the connection between odors and tastes in water and the life histories of its organisms, Prof. Whipple tells us all about different methods of treatment to cure the troubles that attack water-supplies.

The new edition is a book of about the same size as the previous edition, but a brief examination shows that it contains a considerable amount of new material, to keep abreast with the times. There has been a slight rearrangement, by which the space formerly given to bibliog-

*Consulting Engineer, Brookline, Mass.

[illegible] is reduced, and 86 more pages of printed matter added. The plates are now slightly colored as once suggested by ENGINEERING NEWS.

The book is divided into two parts, part one discussing sanitary problems, and part two dealing with a more technical classification of microscopical organisms. The first part has been expanded from thirteen to eighteen chapters, in order to embrace a fuller discussion of different treatments of water-supplies. The question of stripping of reservoir sites is discussed and the use of the microscope is made easier by a special chapter, written by an expert, Dr. John W. N. Banker.

There is nothing left to be desired at the present time in any of the chapters which deal with the collection of samples, methods of examination, limnology, and seasonal distribution of organisms.

In regard to soil stripping, the reviewer thinks that not enough attention has been paid in the public discussions of the subject to the importance of discriminating more fully in the local conditions as regards the desirability of stripping the sites of reservoirs. Even in very large reservoirs, he believes it will eventually be found advantageous to carry out certain modifications of the principles of shallow-flowage treatment and stripping; such, for instance, as were applied to Basins 2 and 3 of the Boston Water-Works System in 1881, 1882 and 1883. There, for a comparatively small expenditure, thousands of stumps were removed which were found to be in a particularly offensive condition of change, shallow-flowage places were filled with loam and mud, removed from adjacent areas, and a better quality of water secured.

The Hopkinton and the Sudbury basins were the only ones of the Boston system where all organic matter was removed from the bottom and sides of the reservoirs and the shallow places filled. In small supplies and small reservoirs, where the incoming water has but little time for improvement by storage, it is especially desirable to consider shallow-flowage treatment and at least partial stripping, and under some conditions, it is desirable to treat the reservoirs to a certain extent even if filtration is to be added. Owing to the fact of the enormous differences existing in local conditions the services of a competent expert are generally required.

All water-works engineers will welcome the chapters on [illegible] growth of organisms in water pipes, and the fine plates and classifications of algae and other growths. Prof. Whipple has done a good life's work already in popularizing the use of the microscope in the solution of important sanitary problems connected with public and private water-supplies. It now only remains for him to show in detail how a large water-supply system like that of the Metropolitan District of Boston is guided almost daily by the studies in its laboratory of the condition of the various reservoirs and the life of the organisms, and how that information is made available in the practical management of the supply.

The [illegible] Steel Co., Chicago, Ill., is rolling six specially slender I-beam sections, which have greater resistance of bending in proportion to the weight than standard I-beams. A little book just issued lists them, and also gives a table covering the standard I-beams. The new shapes are 24, 21, 18, 15, 12 and 10 in. deep, and range 4 to 7 lb. lighter than the American standard section. The addition of a 21-in. section in place of the usual 20-in. I-beam makes the progression of depth more uniform.

These shapes are naturally intended mainly for application in buildings where web thickness and provision of extra thickness against rusting are not usual factors.

Physics for Engineering Students

MECHANICS AND HEAT—By William Ballantyne Anderson, Associate Professor of Physics, Iowa State College. New York and London: McGraw-Hill Book Co., Inc. ("Physics for Technical Students.") Cloth; 6x9 in.; pp. xi + 349; 153 text illustrations. $2, net.

Prof. Anderson here presents the classic elements of physics, though only partially by strictly classical methods of teaching. The volume may be called "elementary" in the sense that it is adapted to first classes of collegiate grade, though it is too advanced a text by which to introduce the subject to a young student for the first time.

The application of natural laws is made real by practical applications at every turn, though the book is not of the "natural-philosophy" variety so much in favor at the present for teaching rudimentary physics. The author, however, does not use the inductive method of reasoning from observed particular phenomena to general laws, but seems to prefer that familiar scheme, which multitudes of teachers are breaking away from, of giving definitions, broad statements and, finally, applications. The author voices the familiar complaint that engineering students lack grasp of fundamental principles of physics; but he does not strike at the root of the evil—the failure of the much tried deductive methods of teaching science to approximate natural mental processes in the investigative mind. The need for improved equipment of engineering students is seen, but the author aims to secure it by overhauling old practices and appending practical application and problems. That makes the teaching text better than some older ones by just as much as it departs from them. It can probably be used with marked success on students who have some previous knowledge of natural phenomena and general laws gained by inductive processes of instruction. But the greatest attainable success, it would seem, is to be secured by pursuing to the limit the procession from particular facts to general laws, for that is what every engineering investigator must do in after life. This text is not in harmony with such a plan.

The book starts with fundamental dimensions and measurements and presents vector quantities; it discusses rectilinear and rotary motions, leading up to general concepts of force, energy and power. Then elementary machines are presented at the end of Part I. Part II concerns itself with the properties of matter—at rest and in motion. Part III includes thermometry, calorimetry, general heat phenomena, meteorology and heat engines.

A GLOSSARY OF ROAD TERMS—By H. Percy Boulnois, M. Inst. C. E., Borough Engineer of Portsmouth, City Engineer of Liverpool, Deputy Chief Engineering Inspector of the Local Government Board. London: St. Bride's Press, Ltd. Cloth; [illegible]; pp. 71. Two shillings net.

Readers of British engineering journals are often puzzled as to the meaning of some of the technical terms used. For instance, "boning" is leveling by eye with crossheads called "boning rods"; "kerb" is a curb; a "[illegible]" is a gulley constructed partly under a "kerb"; a "sump pit" is a "gulley pit," or "catch pit," or in plain American, a catchbasin. There are numerous

other British terms, which we believe the average American reader would need to have defined, if the context did not generally show what our English cousins were writing about. Hence this little book may be of real service to American readers of English highway literature.

A Compendium of Copper Metallurgy

REVIEWED BY PROF. F. W. TRAPHAGEN*

METALLURGY OF COPPER—By H. O. Hofman, Professor of Metallurgy, Massachusetts Institute of Technology. New York and London: McGraw-Hill Book Co. Cloth; 6x9 in.; pp. xiv + 556; 548 illustrations. $5, net.

This second volume in Hofman's new metallurgical series is maintaining the high standard of the first number on "General Metallurgy."

The author has given a very complete review of the subject and the work will serve many metallurgists as a handy compendium on the subject. Matters are discussed in very great detail and the illustrations, in many cases dimensioned, could be used as working drawings. Much valuable information is condensed in the numerous tables.

The more important chapters are those on smelting and on leaching of copper ores and on electrolysis. In attempting to present an exhaustive treatise in which he has fairly succeeded, the author has been compelled to discuss many devices and practices which in some cases are obsolete and in others used only under exceptional conditions.

The experienced metallurgist will be but little embarrassed by this, but the reader of little experience in the metallurgy of copper may have much difficulty in sifting the wheat from the chaff.

One excellent feature introduced in this series is the constant reference to original authority for every important statement. This gives very great value to the work and enables readers to follow up in detail any particular matters in which they may have especial interest.

Numerous typographical errors mar the work. These will, of course, be removed in a second edition, which will be certain to be called for. It is understood that an edition in German is already arranged for and we look for editions in other languages, for the book is especially complete and uptodate.

A final report of the "Committee on Runoff from Sewered Areas," appointed May 1, 1907, by the Sanitary Section of the Boston Society of Civil Engineers, appears in the *Journal* of the Society named for June, 1914. The report describes a number of rain gages and automatic sewage-flow recorders, giving the price of each one available. It also contains text and tables giving the results of rainfall and runoff studies in various cities. There is a bibliography. The report occupies 90 pages. The Committee included George A. Carpenter, City Engineer of Pawtucket, R. I., as Chairman; Harrison P. Eddy, Consulting Engineer, 14 Beacon St., Boston, Mass., as Secretary and six other members.

A paper entitled "Mechanical Treatment of Sewage in Germany," translated from a German article by Dipl.-Ing. Endris, Engineer with the City of Hamburg, Germany, and author of numerous papers on the art of sewage treatment, forms the major portion of a bulletin issued by the Sanitation Corporation, 50 Church St., New York City, bearing the date of May, 1914. Aside from some introductory matter, the paper is devoted almost wholly to the evolution and present design and uses of the Riensch-Wurl screen. This screen has been quite extensively used in Germany, and the company named above proposes to introduce it in the United States.

*Professor of Metallurgy and Assaying, Colorado School of Mines, Golden, Colo.

FIELD MANUAL FOR PLANE SURVEYING AND RAILROAD CURVES—By R. C. Yeoman, Dean of Engineering, Professor of Civil Engineering, Valparaiso University; City Engineer of Valparaiso, and E. A. Tucker, Instructor in Surveying; Assistant in Civil Engineering, Valparaiso University. Valparaiso, Ind.: M. E. Bogarte Book Co. Cloth: 5x8 in. $2.

The new idea in this book is its arrangement and purpose. It is intended to take the place of a text on surveying and to be the field supplement of lectures and assigned reading in standard texts. The size and make up of the pages are similar to a standard field notebook. First comes a double page with sample notes and sketch of an ordinary surveying problem or exercise, then two blank pages for the student to duplicate the problem, or one similar. In this manner the book is divided into seven groups of problems; pacing problems, chaining problems, leveling problems, compass and sextant, transit problems, astronomical surveying and railroad curves. Altogether there are 44 exercises.

There is no criticism of the book, but one may well question the expediency of teaching surveying in this manner. Is it better to tell a young man what you want done and leave it to his initiative and ingenuity to devise the best ways and means, with the help of necessary textbooks and verbal instructions, or to give him a cut-and-dried problem and say, go thou and do likewise? To help train a real engineer we would prefer the former.

POWER AND POWER TRANSMISSION—By E. W. Kerr, Professor of Mechanical Engineering, Louisiana State University. Third edition, thoroughly revised. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. xii+391; 325 illustrations. $2, net.

The changes seen between this, the third, and the previous edition (see these pages for May 14, 1908), are in the nature of making the book uptodate—since it has been widely known as an acceptable teaching text for such technical students (like chemists and some civil engineers) as did not plunge deeply into mechanical engineering, but still required some knowledge of power applications. Some of the changes in illustration evidently have been made to improve the appearance of the pages in the reader's eye.

The most marked peculiarity of this useful compilation of scattered information is its continued silence about electric motors and generators—undoubtedly the simplest and most efficient devices of power transmission. A treatise is not needed on them but something is required for convenience in using this book in class.

INFLUENCE DIAGRAMS for the Determination of Maximum Moments in Trusses and Beams—By Malverd A. Howe, M. Am. Soc. C. E., Professor of Civil Engineering, Rose Polytechnic Institute. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. vii + 65; 42 text figures. $1.25, net.

By systematizing the process of plotting the influence line for any member of a plane truss or frame subjected to moving load, Prof. Howe does a service of great value, particularly to those who—now and in the future—are studying the subject of trusses. The book is written

in a [illegible] short style, which makes it easy to read and [illegible], and it gives us that unusual phenomenon, a small book.

[illegible] bridge engineers at present have a clear idea of the meaning of influence line, they do not make very extensive use of these lines. A simple mechanical rule, by which an influence line can be sketched or drawn in a moment, without analytical study of the frame, is sure to make their use more common. This book should therefore find a large circle of readers and users. The fact that it develops the subject far enough to cover swing spans, arches, etc., makes it worth the study even of the experienced bridge engineer.

A Motorcycle Book and Chart

MOTORCYCLES, SIDE CARS AND CYCLE CARS. A Comprehensive Non-technical Treatise Defining All Forms of the Lighter Self-Propelled Vehicles, Principles of Operation, Construction and Practical Application of Components in Leading American and Foreign Machines. By Victor W. Page, author of "The Modern Gasoline Automobile," "The Modern Gas Tractor," "Automobile Questions and Answers," etc. New York: Norman W. Henley Publishing Co. Cloth; [illegible]. pp. [illegible]; 349 illustrations. $1.50.

LOCATION OF MOTORCYCLE POWER-PLANT TROUBLES MADE EASY—A Complete Chart Outlining the Common Derangements that Interfere with Proper Action of Engine and Auxiliary Systems. Arranged by Victor W. Page, author of "Motorcycles, Side Cars and Cycle Cars," etc. New York: The Norman W. Henley Publishing Co. Heavy Paper. Sent prepaid to any address on receipt of 25c.

Two previous books by this author on the modern gasoline automobile and on questions and answers relating to automobile design were reviewed in these columns on Feb. 13, 1913, and Jan. 15, 1914. The present book is similar in style to the previous volumes but deals exclusively with motorcycles and their recent development into what are known as cycle cars. The book is somewhat more elementary in its treatment than the books relating to automobile work above referred to, but like them is deserving of high commendation for the thoroughness and [illegible] of the treatment given to the subject.

This book should prove a useful aid to the numerous [illegible] who own and use motor bicycles. It is doubtful, however, whether the cycle car will have any such large use in this country as it has secured in France and England. The very low price at which a regular automobile can be procured in this country makes it difficult for the cyclecar manufacturers to compete with them. [illegible]

[illegible]

C. H. [illegible], 1307 E. [illegible] St., Cleveland, Ohio, [illegible] a [illegible] chart of the familiar parallel-scale variety, which is printed on a matt-surface celluloid. The chart can be used by drawing pencil lines across the scales instead of merely laying a ruling edge across, and in this way is considerably more useful or convenient than a chart without this feature. The scales are arranged for both steel and wooden beams; in the case of steel beams they indicate the depth and section directly.

OIL PRODUCTION METHODS.—By Paul M. Paine, Assistant Superintendent, Honolulu Cons. Oil Co., and B. K. Stroud, Petroleum Engineer, formerly Superintendent, Monte Cristo Oil & Dev. Co., Field Superintendent, Universal Oil Co. With a Chapter on Accounting Systems by W. F. and W. B. Sampson, Expert Accountants with Klink, Bean & Co., San Francisco, Calif. Western Engineering Publishing Co. Cloth; 6x9 in.; pp. 240; 216 text illustrations. $3, postpaid.

According to the preface this book has been prepared in response to a demand for a work describing, in a manner that may be understood by the layman, how oil wells are drilled and oil produced. The first two chapters are of general interest, describing the distribution, properties and uses of petroleum and the geological conditions under which it is found. The next two chapters describe drilling equipments and methods, and are of interest to those who have to make drill holes for other purposes as well. The fifth chapter covers the exclusion of water from oil sands, and the other three chapters describe the operation of the wells, handling of the crude oil and an accounting system for the business-like conduct of oil-well operation.

SYMMETRICAL MASONRY ARCHES. Including Natural Stone, Plain-Concrete and Reinforced-Concrete Arches. For the Use of Technical Schools, Engineers and Computers in Designing Arches According to the Elastic Theory.—By Malverd A. Howe, M. Am. Soc. C. E., Professor of Civil Engineering, Rose Polytechnic Institute. Second edition, revised and enlarged. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. xi + 241; 35 illustrations and 6 folding drawings. $2.50, net.

Some important additions make this second edition a distinct modernization. However, the favorable comments by Prof. Wm. Cain, in reviewing the first edition in our issue of Nov. 15, 1906, give as good a characterization of the book now as then. The tables of arches have been supplemented by a table giving arches built within the last ten years. The arch-coefficient method presented by the author in Engineering News of June 2, 1910, forms the 10-page Appendix B; its tables of coefficients will be found of much use. Formulas for unsymmetrical arches are grouped in another appendix, thus serving the occasional need where symmetry cannot be maintained.

The author says that most of his text has been rewritten.

Our attention has been called to an error in the heading to the brief review of [illegible] Congrave's "Rock Excavating and Blasting" printed in our issue of May 21. The book was published by the author and not by the National Fire-Proofing Co. of Pittsburgh, as stated in the review. The material comprising the book, however, had appeared in serial form in a magazine entitled "Building Progress," published by the company named. Mr. Congrave may be addressed at 21½ W. [illegible] St., Philadelphia, Pa.

PROCEEDINGS OF NATIONAL CONFERENCE ON CONCRETE ROAD BUILDING—Held at Chicago, February [illegible], 1914. [illegible] Secretary, [illegible] Chicago. Paper; [illegible].

At the closing session of the National Conference on Concrete Road Construction, held at Chicago last Febru-

ary, it was voted that the full proceedings of the conference should be published. There were presented at that conference the reports of 15 committees, each of which dealt with some especial feature of concrete road work. Each of these committee reports received more or less discussion. There were also half a dozen papers and addresses. All this matter has just been issued in a well printed and well bound volume, which will doubtless receive the careful study of every engineer in any way interested in the subject of the conference. The volume opens with several pages on recommended practice in concrete road building, which were adopted by the conference, as reported by the Committee on Resolutions.

Electrical Insulations

MOLDED ELECTRICAL INSULATION AND PLASTICS—By Emilie Hemming. New York: Ward Clausen Co. Cloth; 5x8 in.; pp. 207; 36 plates and text figures. $3.

Mr. Hemming has succeeded in producing that modern rarity in technical literature, an entirely new book. The literature of electrical engineering, chemistry, ceramics, etc., has scattered through it, of course, a large amount of material relating to modern insulating materials, especially those of the plastic varieties, but so far as we are aware, all the information available on these products has remained scattered until this attempt to present it between the lids of one volume.

The author describes the advances which have been made, particularly in late years, in molded insulations for all sorts of electrical service, and then classifies the products of the present day under nine heads—organic hot-molded, organic cold-molded, inorganic cold-molded, ceramics, rubber compounds, organic plastics, synthetic resins, hardened fibers, molded mica. Before discussing the several classes in further detail, some forty-five pages are devoted to a description of the raw materials which enter into all of these various classes. This description includes the fundamental chemical elements, mechanical properties, etc., of a great variety of materials—asbestos, clay, mica, silica compounds, cement, earths, resins, vegetable fibers, mineral waxes, oils, solvents, rubber, and chemicals such as phenol, formaldehyde, etc.

Then follow details of making and using the classes of materials. All this material is reduced to its simplest and briefest form and should be understood without especially deep knowledge of chemistry, electricity or even of manufacturing processes. In the first group ("Class A, hot-molded organics") is discussed the use of shellac binders (or substitutes) with wood pulp, magnesia, lime, sand and asbestos. In the second group ("Class B, cold-molded organics"), the materials employed are much the same, but solvents take the place of heat in obtaining fluidity. The third group ("Class C, cold-molded inorganics") uses compounds of silica, alumina, lime and magnesia, or hydraulic cements with the same inorganic fillers named. "Class D" covers ceramics; "Class E," rubber compounds; "Class F" organic plastics—celluloid and casein; "Class G," the synthetic resins resulting from the reaction between phenol and formaldehyde; "Class H," vulcanized fiber; and "Class I," mica imbedded in binders.

The physical properties of completed articles are reviewed—life, ease of working, dielectric strength, mechanical strength, resistance to weather and heat, chemical inertness and appearance. Here is restated, under these respective heads, what is related before in discussing the several materials.

There is a long section on the limitations of molding and the attention that has to be given to good design of dies. Some 18 full-page plates illustrate various articles molded from these several varieties of material; accompanying page texts describe their use and note reasons for using the particular materials shown. Finally the results of some definite electrical, mechanical and thermal tests are shown.

How to Cast Steel

THE STEEL FOUNDRY—By John Howe Hall, Consulting Engineer. New York and London: McGraw-Hill Book Co., Inc. Cloth; 6x9 in.; pp. ix + 271; 37 text illustrations. $3, net.

REVIEWED BY WM. R. CONARD*

The author gives a comprehensive description of the various processes of steel founding.

As a book for use in our institutions of learning, it should be of value to both the teacher and the student.

Again, it is of value to the man who is a consumer of steel in that it describes plainly the results obtained by the various processes and the advantages and disadvantages of each process.

It is particularly valuable to anyone entering this branch of industry or investing money in this line in that it gives in addition to the various processes, well considered estimates of costs and similar data which the layman might not know how to figure out. And in the last place, it is of especial value to the man who is actively engaged in the steel business as it brings all of the various methods under one cover, describing them all. The author has apparently endeavored to cover all phases of the industry from the factors which enter into the choice and cost of a given process to the laboratory where the results of the processes are analyzed.

PUBLIC ROADS AND HIGHWAYS COMMISSION OF ONTARIO—Report of 1914. Toronto: Office, Commissioners of Public Roads. Cloth; 7x10 in.; pp. 277; illustrated, and accompanied by six folding maps.

In addition to the regulation highway-commission report, this book is of interest because it contains a compendium of highway organizations in Canada and the United States. There is also a very interesting historical sketch of road development in Ontario. The most important part of the report is perhaps a study of the relation of farm values and agricultural improvement to highway improvement in the Province of Ontario.

A short, popular, but useful and forceful account of the "Salem Conflagration" (Salem, Mass., June 25 and 26, 1914) has been written by Franklin H. Wentworth and published by the National Fire Protection Association (87 Milk St., Boston, Mass; price 10c.). Lessons from the fire are, of course, drawn. A folding map and a few halftone views are included.

A table for estimating the cost of joints in 4- to 18-in. cast-iron pipe has been compiled for distribution by the Leadite Co., of Philadelphia, Penn. It shows for both lead and leadite the pounds of calking material required per joint, and the cost per joint, per foot of pipe and per mile of pipe. The quantities and costs given are based on American Water-Works Association standard

*22 High St., Burlington, N. J.

[illegible] parts. The table has been printed on a [illegible] card, and although issued primarily for advertising purposes, will interest water-works men.

NEW PUBLICATIONS

[As far as possible the name of each publisher of books or pamphlets listed in these columns is given in each entry. If the book or pamphlet is for sale and the price is known by the editor the price is stated in each entry. Where no price is given it does not necessarily follow that the book or pamphlet can be obtained without cost. Many, but not all, of the pamphlets, however, can be secured without cost, at least by including postage. Persons who are in doubt as to the means to be pursued to obtain copies of the publications listed in these columns should apply for information to the stated publisher, or in case of books or papers privately printed, then to the author or other person indicated in the notice.]

ABWASSERREINIGUNGSANLAGEN IHRE LEISTUNGEN UND IHRE KONTROLLE VOM CHEMISCH-PRAKTISCHEN STANDPUNKT—Von Prof. Dr. K. Thumm, Abteilungsvorsteher an der Königl. Landesanstalt für Wasserhygiene in Berlin-Dahlem. Berlin: August Hirschwald. Paper, 6x9 in., pp. 92. 2.80 Marks.

ADDENDUM, BEING THE FIVE CHAPTERS ON MODERN ROAD CONSTRUCTION Reprinted from "Asphalts" 1914 Revised Edition—By T. Hugh Boorman. New York: The William T. Comstock Co., 23 Warren St. Paper; 7x10 in., pp 169-191, illustrated. 25c. if sold separately; incorporated in new edition of book, price of which is $2.

AIR-BRAKE CATECHISM The Only Practical and Complete Work Published Treating on the Equipment Manufactured by the Westinghouse Air Brake Company, Including the ET Locomotive Brake Equipment; the K (Quick-Service) Triple Valve for Freight Service, the Type L High-Speed Triple Valve, the P C Passenger-Brake Equipment and the Cross Compound Pump, The Operation of All Parts of the Apparatus Is Explained in Detail, and a Practical Way of Finding Their Peculiarities and Defects with a Proper Remedy Is Given—By Robert H. Blackall. Entirely revised to date. New York: The Norman W. Henley Publishing Co. Cloth; 4x7 in.; pp. 411. 179 illustrations. $2.

AMERICAN MACHINISTS' HANDBOOK and Dictionary of Shop Terms. A Reference Book of Machine Shop and Drawing-Room Data, Methods and Definitions—By Fred H. Colvin, M. Am. Soc. M. E., Associate Editor of the "American Machinist," author of "Machine Shop Arithmetic," "Machine Shop Calculations," "American Machinists' Grinding Book," "The Hill Kink Books," etc., and Frank A. Stanley, M. Am. Soc. M. E., Associate Editor of the "American Machinist," author of "Accurate Tool Work," "Automatic Screw Machines," "American Machinists' Grinding Book," "The Hill Kink Books," etc. Second edition, thoroughly revised and enlarged. New York and London: McGraw-Hill Book Co. Leather; 4x7 in.; pp. xxvi + 6[illegible]; numerous illustrations. $3.

FLIGHT WITHOUT FORMULAE. Simple Discussions on the Mechanics of the Aeroplane—By Commandant Duchêne, of the French Génie, author of "The Mechanics of the Aeroplane." Translated from the French by John H. Ledeboer, Editor, "Aeronautics," joint-author of "The Aeroplane." New York and London: Longmans, Green & Co. Cloth; 6x9 in.; pp. 211; 84 text figures. $2.25, net.

VOLUME 72 — AUGUST 27, 1914 — NUMBER 9

The Design and Construction of the Bassano Dam: Part I

By H. B. Muckleston*

SYNOPSIS—A part of the immense irrigation system of the Canadian Pacific Railway, southeast of Calgary, is a composite dam consisting of an earth embankment 7000 ft. long and 35 to zero ft. high, an Ambursen hollow reinforced-concrete dam, 750 ft. between abutments, 39 ft. high to the crest, which is divided into 24 openings each 27 ft. long, provided with Stoney gates 11 ft. high; and a reinforced-concrete headwork, at right angles to the dam proper, having five 20-ft. openings, closed by Stoney gates 14 ft. high. The dam is designed to pass 100,000 sec.-ft. of water with 14 ft. on the crest. The dam rests on a stratum of clay, beneath which is sand containing water under slight pressure. The floor of the dam is pierced by weep-holes and iron pipes extend from the bridge level of the dam to and through the clay. A floating timber apron is placed below the dam. Construction was carried on in extremely cold weather. Salamanders beneath tarpaulins supported on horses were used to thaw frozen ground to a depth of 6 ft. for excavation. Concrete work was not stopped until the temperature fell below —15° F. The water and gravel were heated and all forms were double boarded. The sluice gates are protected against frost by housing and by an electric-heating system.

The Canadian Pacific Railway Co. has recently completed, as a part of its great irrigation project, one of the most notable overfall dams now in existence.

The dam, which is located on the Bow River, about one hundred miles southeast of Calgary, is noteworthy not only because of its dimensions and the composite character of its construction, but also because of the unusually great depth of water which it is designed to pass over its crest during floods.

The Irrigation Project

The map, Fig. 1, gives a general idea of the country covered by the irrigation system and shows, besides the main canals and ditches, the location of the principal watershed and drainage lines. It will be noted that much of the greater part of the irrigated area is on the North or Red Deer River slope of the divide, and that consequently only a fraction of the water diverted will ever return to the Bow River. The total irrigable area commanded by the system is, in round figures, some 440,000 acres. The canal system, to reclaim this large area, involved moving some 21,000,000 cu.yd. of excavation in all classes; over 100,000 cu.yd. of concrete were built into the structures on the main, branch and secondary canals; and 9,500,000 ft. b.m. of timber were used in flumes, bridges and the structures on the smaller ditches and laterals. The total mileage of canals and ditches is in excess of 3000. It will be seen, therefore, that the project is exceeded in magnitude by few outside India and by none on this Continent.

The first surveys for this project were made by the writer in 1906. They were confined to securing general information and to making rough estimates of the area which could be irrigated and the cost of the diversion

Spillway or Overfall Portion of Bassano Dam, Canadian Pacific Irrigation Project

*Assistant Chief Engineer, Department of Natural Resources, Canadian Pacific Railway, Calgary, Alberta.

works, based on several assumptions as to crest elevation of the proposed dam. These surveys showed that the project was feasible from an engineering point of view

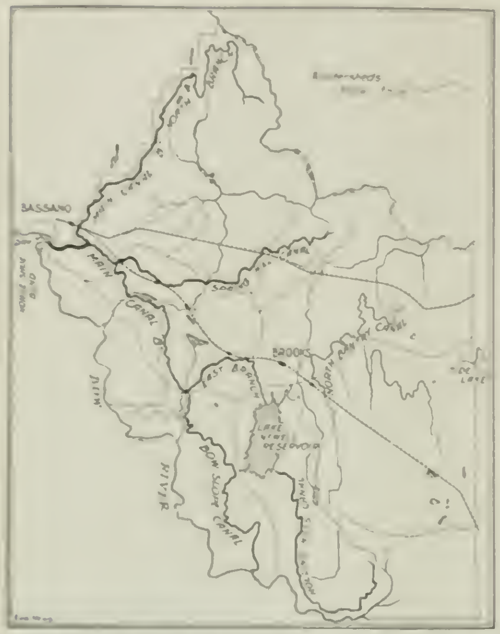

FIG. 1. MAP OF CANADIAN PACIFIC IRRIGATION SYSTEM, EAST OF CALGARY, ALBERTA

and that it could be built within the limit which had been set as to cost. Further surveys were made in 1909, and the crest elevation finally fixed after several alternative preliminary locations of the larger canals and a closer examination of the areas which they commanded.

DESIGN OF THE DAM

It will be noted from the map, Fig. 1, that at the point B (Bassano) the divide between the rivers is very close to the Bow, only 600 ft. away in fact. At this point begins a wide valley known as Crawling Valley, which cuts clearly across the country from the Bow River to the Red Deer. Toward the Red Deer River it falls about 40 ft. in 15,000 ft. in the upper reaches, while toward the Bow the fall is 90 ft. in [illegible] ft. The average depth of this valley is about 70 ft., and its width about 600 ft. As the summit of the pass [illegible] was [illegible] 30 ft. above the river it offered a splendid opportunity to divert water for irrigation, provided it proved feasible to construct a dam of some height across the river valley.

Fig. 2 is a general site plan showing the location of the dam. The left bank of the river, which forms the outside of the horseshoe, is a high clay cut bank or cliff, varying from 150 to 200 ft. in height, with practically no beach whatever at the bottom except in very extreme low water. The right bank or inside of the horseshoe is a gravel beach gradually sloping up to a silt bank at high-water mark. The tongue of land inside the horseshoe slopes gradually up from the toe of the slope to the general bench elevation of the adjoining country. It shows visible evidence that it has been built by the river, as the stream gradually cut its way down and widened the sweep of the curve.

Fig. 3 is a general profile showing the result of the borings put down to determine the character of the foundations. Under the clay at a varying depth is a stratum of unknown thickness composed of a coarse water-bearing sand, not quite free running but weakly cemented. Most of the boreholes were stopped when the sand stratum was reached, but a few were carried deeper in an effort to reach the bottom of the sand, though without any success. It was found that the water in the sand was under a slight pressure, which was measured and found to correspond roughly with the fall in the surface of the river in a distance of about 3000 ft. This was thought to indicate that the overlying clay pinched out somewhere upstream, and three boreholes were put down to ascertain if this was so. It was found that at 2600 ft. upstream from the site the clay was only 2 ft. thick. The theory that the water found access from the river was confirmed by subsequent observations on the pressure head in the sand compared with parallel readings of a gage rod in the river. The similarity of the curve was unmistakable, though there was a lag in phase amounting to 30 hr., for which no satisfactory explanation has yet been offered.

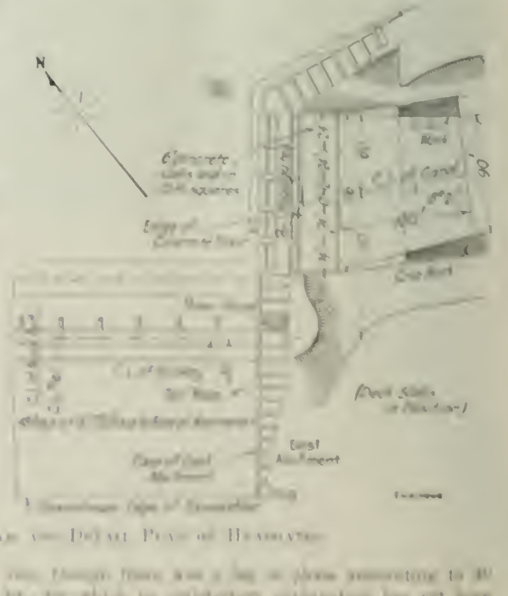

FIG. 2. GENERAL PLAN OF BASSANO DAM AND DETAIL PLAN OF HEADWORKS

The strata under the tongue of land inside the horse-

shoe are similar to those under the river except that the gravel layer is very much thicker and is overlaid by a stratum of silt left behind by the river as it gradually cut its way down.

When the dam was first proposed, very little was known of the hydrology of the river, the few discharge records that were available being unsatisfactory in that they gave little or no indication as to the maximum floods which might be expected. The only refuge, therefore, was a careful series of gagings and a search for flood marks. From these gagings and what flood marks could be found it was estimated that a flood of 100,000 sec.-ft. was possible, and the dam was designed to pass this quantity with 14 ft. of water on the crest. This corresponds to a runoff of 12.5 cu.ft. per sec. per sq.mi. from a drainage area of 8000 sq.mi.

The range in discharge of the river is very wide, varying as it does from a minimum in winter of about 1200 sec.-ft. to the calculated flood discharge above given. Ordinary spring and summer freshets seldom rise much above 30,000 sec.-ft., though considerably larger floods of short duration are not infrequent.

The time factor in flood rises in the Bow is important, variations of 20,000 sec.-ft. in discharge in 10 or 12 hr. being by no means unusual and often coming without much warning. Owing to the narrow valley and steep slope of the river bed the pondage area above the dam is comparatively small, not over 3500 acres, during low stages. It was therefore very necessary that means be provided for rapid working of any crest sluices, and also that the earth dam be given an unusual freeboard above ordinary pool level.

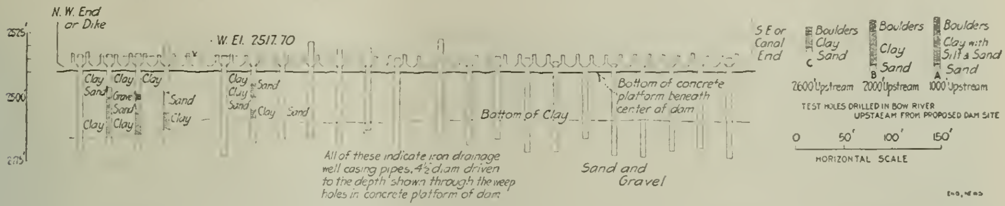

FIG. 3. MATERIAL PENETRATED BY DRAIN PIPES 9 FT. UPSTREAM FROM CENTER LINE OF BASSANO DAM

The dam as finally built consists of two or rather three parts: (1) an earth embankment 7000 ft. long, built on the right bank inside the horseshoe; (2) a reinforced-concrete spillway section, built in the river bed; and (3) a reinforced-concrete canal headwork built at right angles to the spillway and integral with it.

The embankment varies in height from 35 ft. to zero. It was designed to have a top width of 24 ft., with 4 to 1 wet slope and 3 to 1 dry slope, and to have a freeboard at ordinary high stages of 9 ft. The thickness as built is much in excess of what the above dimensions would indicate, as a large surplus of material from the canal cut was wasted over the back of the earth dam, resulting in a top width varying from 40 to 100 ft. The wet slope is protected from erosion by a concrete paving surmounted by a curved parapet wall to prevent any wave wash from going over.

The spillway is 720 ft. between abutments. It is of the typical Ambursen section (Fig. 4). The crest is divided into 24 openings, each 27 ft. long, closed when required by Stoney sluices 11 ft. high. The headworks consist of 5 openings, each 20 ft. wide, closed by Stoney sluices 14 ft. in height.

The general design of the composite structure was determined by the Railway Company's engineers after a careful study of all the conditions above outlined. Having decided that the cellular type of reinforced-concrete construction would best meet requirements for the spillway and headworks, the detailed design of these parts was placed in the hands of the Ambursen Company, who also undertook the superintendence of construction. All drawings were approved by the Railway Company's engineers before becoming effective. Both design and construction were carried out under very complete specifications approved by both the Railway Company and the Ambursen Company.

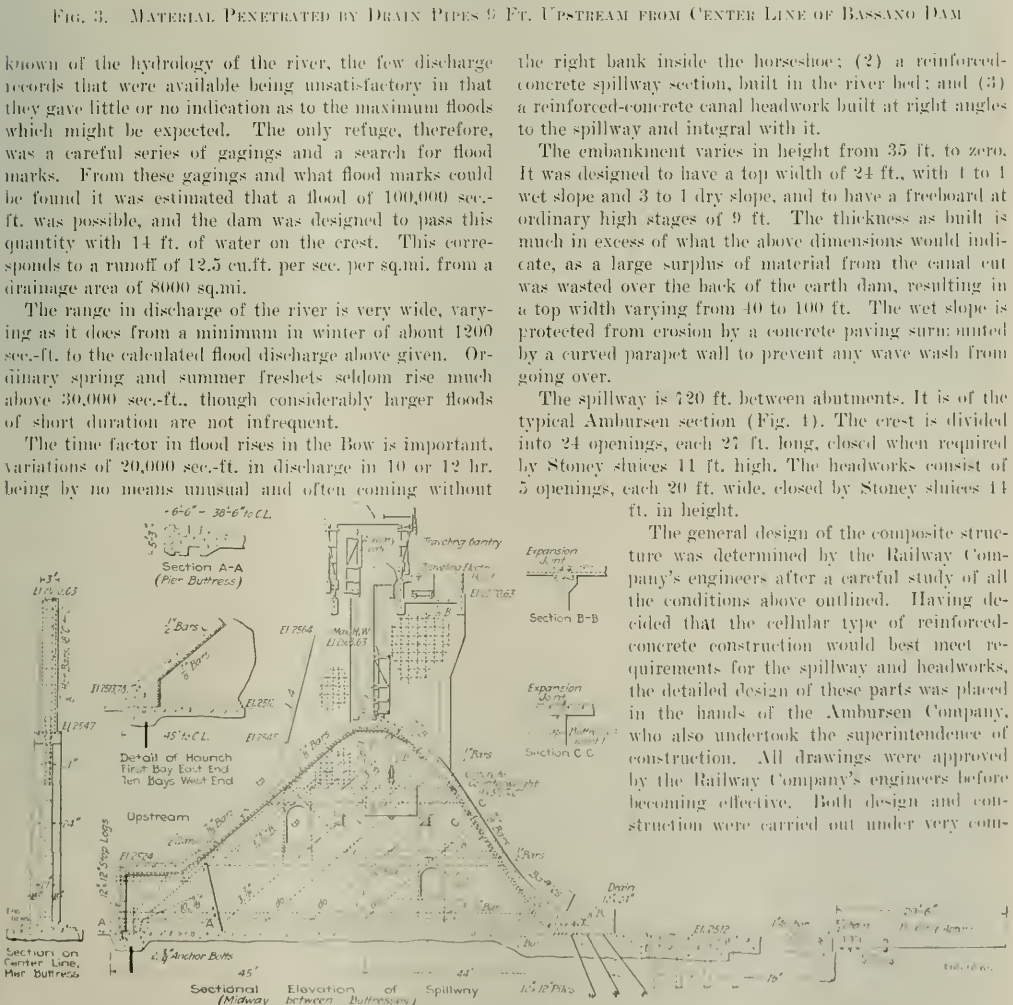

FIG. 4. SECTIONS OF BASSANO DAM

The maximum allowable unit stresses used in the design of all parts of the structure were as follows:

Bearing power of foundations	2.5 tons per sq. ft.
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]

All the above maximum unit stresses are considered [illegible] based on [illegible] due to the greatest external flood head, namely, 14 ft. above [illegible] and no allowance made for effect of ice [illegible].

For all members of the structure the steel is so designed as to take the entire tensile stress without aid from the concrete. For all bottoms, walls, [illegible] steel is inserted in such quantities as will insure against [illegible] cracking due to temperature stresses and vibration.

All cement was tested at the works and [illegible] to conform to the specifications of the Canadian Society of Civil Engineers.

[illegible]

As mentioned above, the water contained in the sand stratum is under pressure, and strong presumptive evidence existed that this pressure was equivalent to the head of a point about 3000 ft. upstream. If the presumption were true the upward pressure on the clay might, under certain circumstances, be more than the superincumbent weight, and accordingly steps were taken to relieve it. This was accomplished by twenty-four 5½-in. [illegible] wells bored through the clay and extended [illegible].

Sluice Gates—Of the sluice gates, a great many different types were considered, the choice finally narrowing down to Tainter gates as against the Stoney free-rolling pattern. The latter were finally decided on, for, while the Stoney involved a considerable increase in cost, it was felt that they would be better suited to the conditions and more certain in operation. The gates are handled from [illegible] and are counterweighted to [illegible] of their [illegible]. The [illegible] is calculated for a loading [illegible].

[illegible]

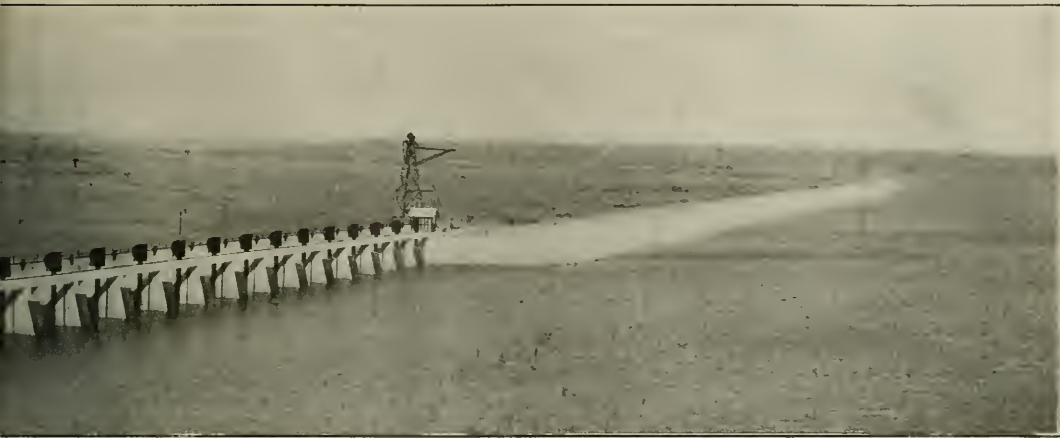

FIG. 6. HEADGATE STRUCTURE, SPILLWAY AND EARTH EMBANKMENT OF BASSANO DAM

PROTECTION OF SLUICE GATES AGAINST FROST BY HOUSING AND ELECTRIC HEATING—One of the problems in the design of the dam to which a great deal of study was given was the effect of the peculiar winter climate on the structure and its operation. One of the salient features of the irrigation project is the large interior reservoir lying south of Brooks—Lake Newell on the map (Fig. 1). It is intended to fill this reservoir during the winter months when the canals are not required for irrigation purposes. This involves very delicate control of the discharge of the canals in order to avoid trouble from ice jams and consequent possible breaching of the canal banks. It will be seen, therefore, that under no circumstances must the crest sluices ever be allowed to become inoperative through frost. To guard against this a very complete system of electric heating for the gates has been installed and special precautions in the way of housing have been taken to insure that all the canal head sluices and two of the crest sluices shall be free from ice at all times.

The effects of ice shove or expansion on the static stability of the dam were very carefully considered and allowed for. It was felt, however, that even so it would be wise to treat the cause rather than the effects, and steps are therefore taken to keep a trench open close above the piers.

Fig. 6 shows across both pages the entire dam and headgate structure at Bassano Dam. On the left is the headgate and stretching away to the far background on the back is the earth embankment.

The construction of the dam will be described in a later issue.

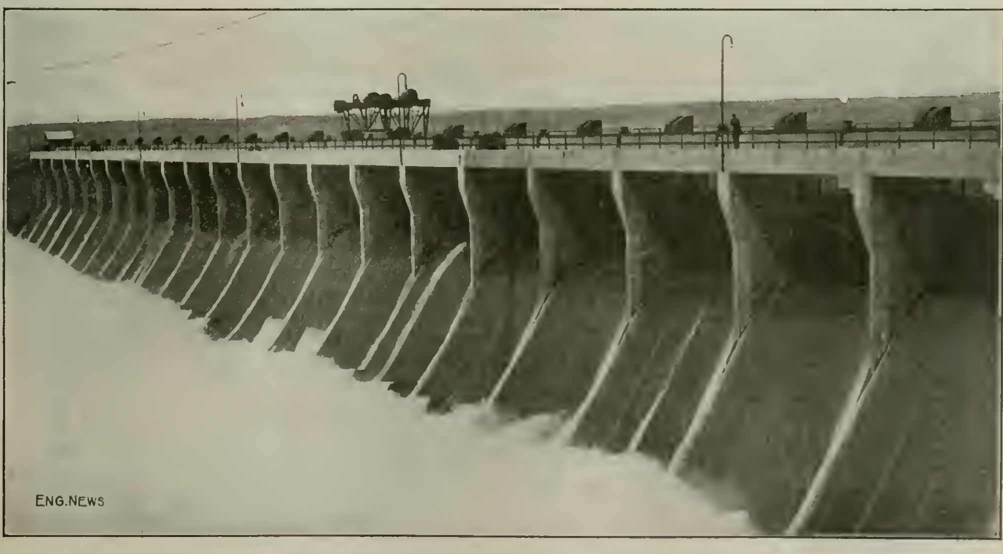

FIG. 7. BASSANO DAM, LOOKING UPSTREAM AFTER COMPLETION

Construction of a Small Sewerage System for Garfield, N. J.

By Russell S. Wise*

The construction of some 30 mi. of sewers for Garfield, N. J., partly in wet ground, the laying of house connections and other features of this work, including record keeping, seem worth putting on record in view of the comparatively little recent information regarding such work readily available to engineers.

Garfield, N. J., a borough in Bergen County, lies about 12 mi. west of New York City. It has an area of about [illegible] sq.mi., and a present population of over 12,000. Topographically, it is broken into three ridges, with the valley of the Passaic River on the west, the Saddle River Valley on the east and south, and the flat land of Saddle River Township on the north.

In designing the sewer system of the borough of Garfield, it was decided at the outset [illegible] to drain to three points on the Passaic River and to discharge a small system into the Saddle River. Four sewage treatment plants were planned; three, each of a capacity of 1,000,000 gal. daily, were to be built on the easterly bank of the Passaic River, and the fourth, having a capacity of 100,000 gal. daily, was located on the north bank of the Saddle River. Those which were to be built along the Passaic River were intended to be abandoned as soon as the auxiliary sewer to be constructed by the Passaic Valley Sewerage Commissioners was in readiness to receive the sewage of Garfield.

The sewerage system, as designed, covered all of the streets, [illegible] and proposed, which were shown upon the official assessment map of the borough. The sewers have, however, been built only in the most populous sections of the borough. Up to July, 1914, about 30 mi. of main sewers have been constructed. Connections from the sewers to the curb have, in all cases, been laid.

The system, which is now considered to be completed, has cost about $[illegible]. Of this sum, a bond issue of $[illegible] was voted by the people to defray the cost of the [illegible] sewers and disposal plants. The remainder of the cost was met by moneys raised from the sale of improvement certificates [illegible] [illegible] at [illegible] and afterwards changed to [illegible] when it was found difficult to dispose of these certificates at the lower rate.

The contract was let to [illegible] & [illegible], of [illegible], N. Y., and the work began July [illegible], 1911.

Trenching machines were used upon most of the work. [illegible] machines [illegible] the most satisfactory work on a good deal of the trenching in the [illegible] sections of the borough was in [illegible] [illegible] with boulders and occasional layers of red shale. The [illegible] [illegible] of this material, boulders and shale, with [illegible] to itself. When sheeting was necessary, the machine's elevating wheel was hoisted to the top of the trench, legs were cleared and placed in position and the [illegible] and the sheet [illegible] without injury to any portion of the machinery, and no loss of time in moving the machine occurred. In [illegible] the machine [illegible] from [illegible] to [illegible] lin.ft. of trench [illegible] ft. in depth per day of [illegible] hours.

In the central portion of the borough, ground water was encountered at a depth of 1 to 10 ft. below the surface, in fine sand and some distance down in a bluish clayey quicksand which resembled thick blue paint. No attempt to lay the sewer pipe in water was made.

In excavating in quicksand, or quaking soils, it was found that laborers, with strong backs, who would stand very still, could skim off the soil in thin layers without causing any appreciable flow of water and the bottom of the trench would be in excellent condition to place a foundation of gravel and sand; whereas, the laborers who moved around and used their feet in digging would soon bring about watery conditions. The trench would cave in and come up under the sheeting almost as fast as it was dug out and so cause trouble and expense in laying the pipes.

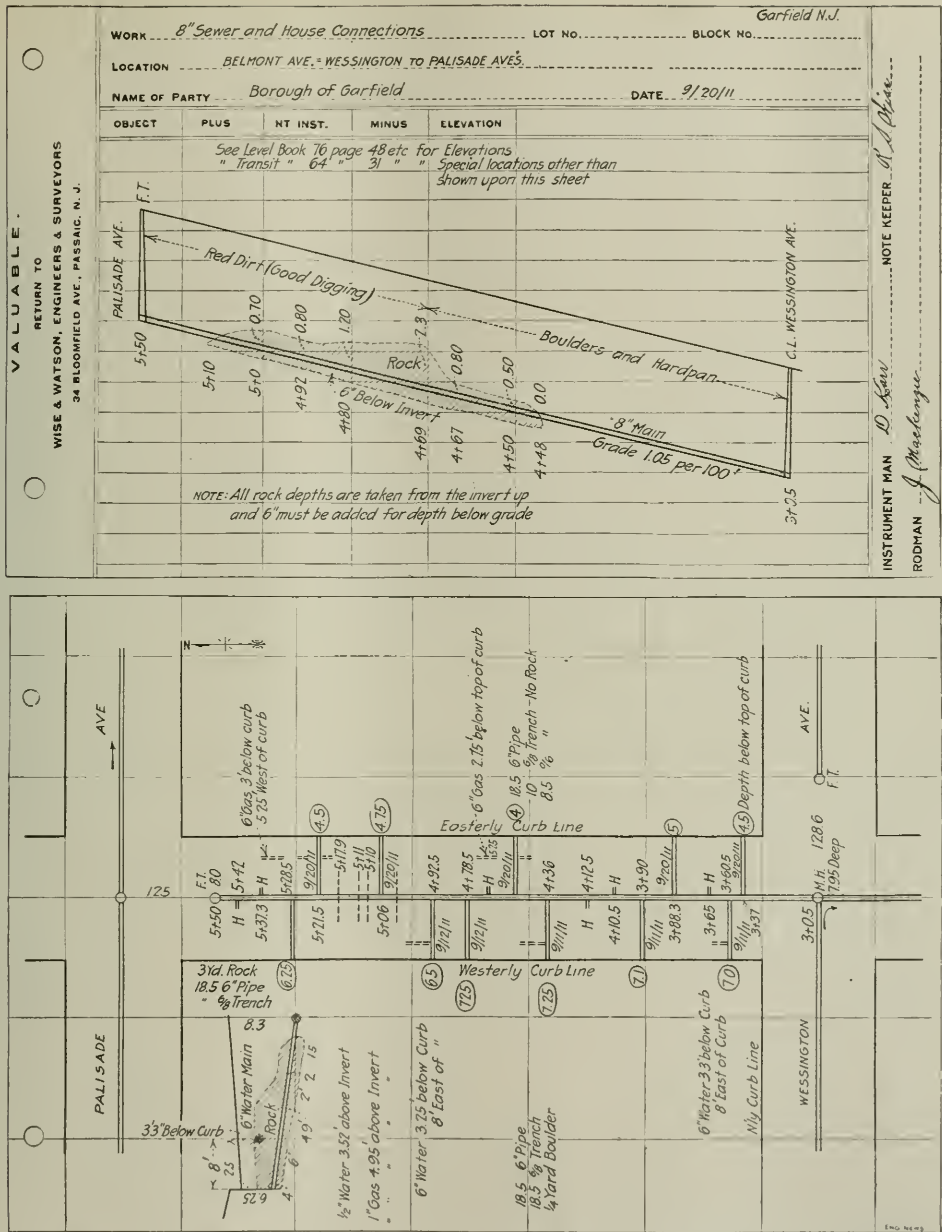
In all quicksand trenches, foundations of gravel, varying in depth from 6 to 18 in., depending upon the nature of the material, were laid. The extra excavation for the foundations was paid for by the cubic yard. The gravel foundations seemed to check the flow of water sufficiently to lay the pipe, and proved very satisfactory. In a few cases, where the gravel foundations did not fulfill the requirements, concrete was placed upon the gravel. This was done by excavating the trench 50 to 60 ft. in advance of the pipe and tamping a comparatively dry mixture of 1:3:5 concrete into the gravel. After leveling the concrete to within 1 in. of the grade of the outer bottom of the bell of the pipe, the concrete was allowed to set 24 hr. The pipes were then laid upon this foundation by raising the grade of the trench with the same mixture. After jointing, as described further on, the concrete was raised to the springing line of the pipe and in some cases was sloped from the springing line to the top of the pipe. The backfilling with dry material then proceeded, covering the pipe about 2 ft., and the balance of the trench was filled with the original material. So far the pipes seem to be in good line and grade.

In sheeting quicksand trenches, a strip of sheet iron about [illegible] in. wide and the length of the sheeting was nailed on one edge of the planks, the sheeting being driven with the sheet iron on the outside of the trench. The sheet iron overlapped every joint and the pressure of the earth outside forced the iron tightly against the sheeting and so made a very nearly watertight sheeting. Where concrete foundations were placed and the sheeting [illegible] to be left in, this proved to be very [illegible].

A special or cloth-wrapped joint was used in all wet trenches. This was made by tying a strip of cloth about [illegible] in. wide and [illegible] in. longer than the length of the circumference of the pipe. The cloth was [illegible] both ends about [illegible] in. wide and one-quarter the length of the cloth [illegible] [illegible] the [illegible] end of the pipe. The pipe was then placed in the trench and after setting true to line and grade and calking the joint with [illegible] [illegible] [illegible] of the [illegible], which was of the [illegible] and [illegible] [illegible], a 1:1 mixture of sand and cement was tightly pressed into the joint and neatly beveled. The cloth was then drawn over the joint and rubbed on the outside with neat cement. With this joint there was little danger of water leaking into the pipe or of the cement being washed from the joint, and at the present time there has been very little ground water noticed in the sewers.

House connections, of [illegible] pipe, were put from the

*[illegible] [illegible] [illegible] [illegible] [illegible] in charge of construction of Garfield sewers.



Final Record Plan and Profile of One Block of the Sewerage System of Garfield, N. J.

sewer to 1 ft. inside of the inner face of the curbs. As the work progressed, each property owner was consulted as to his wishes and the connection placed just where he wanted it. Hubs were placed in front of every 25-ft. lot in addition to those connections run to the curbs. Where there was much vacant property, connections were run to the curb at the rate of about five to the hundred feet of sewer.

Chimneys or standpipes were built on all sewers where the depth was 12 ft. or more below the established grade of the street. They were encircled with a 6-in. shell of concrete extending from a point 6 in. below the outer bottom of the pipe to the bends from which the house connections were run. Wherever it was practicable, in order to serve two opposite houses, the chimneys were topped off with Y's and the cost so divided, for under the

assessment of the costs, the costs of such house connection must be kept separate and assessed upon the property according to its actual cost. The cost of the main sewers is to be assessed in accordance with the usual rule.

The keeping of the records for the house connections was much more difficult than that of the main sewers, as many of them were laid months after the main sewers were laid. During construction of the sewers, the position of the house connections was determined and the station marked on the face of the curb, or where there was no curb, at right angles to the Ys which were placed in the sewers. Besides helping to keep the records correct, this was a great help to the contractor as considerable time would have been lost if the engineer or inspector having the location of the connections was on some other part of the work. Where it was decided to carry the connection to the curb, the letter "C" was marked upon the curb or fence and at intermediate points where Ys only were to be placed for future connections, the letter "H" was marked upon the curb. After these connections had been inserted and approved, the letters were cut in the curb which would enable the plumbers to readily find the pipe. When the connection was inserted, the station was recorded, together with the length of pipe laid, the depth of trenching under the different classifications, the rock, special joints and any special work. From such data the engineer was enabled to prepare the final drawings, showing in detail, block by block, everything which would be required by the assessment commissioners in preparing their report of assessments, also by those in charge of the operation and maintenance of the sewer system. A record was also kept of all underground structures, such as drains, water and gas pipes, which might be useful in other improvements of the streets of the borough. A record plan and profile are reproduced herewith.

The backfilling was done with a backfilling machine, designed and built by Mr. Martin, of the firm of Martin & Miller. The trench was settled with a water jet, the water being furnished by the borough at the rate of $1.10 per 1000 cu.ft., measured by a meter attached to the hydrants. This method effected a big saving to the contractor as they could backfill a much greater length of trench per day than would otherwise have been possible.

Cost of a Damp-Proof Timber Floor

By J. [illegible]*

Engineers are frequently called upon to design and build floors in industrial buildings where water under a head is not encountered, but where protection against dampness must be provided. This applies to basement and ground floors where the practice was formerly to carry such floors on heavy timbering, supported by piers, thus providing an air space and lately usually by laying the floor directly on a concrete base and spiking to strips embedded in the concrete.

Neither of these methods proved ideal. Most recent and successful practice is to introduce a damp-proof construction under the wood surface directly on the ground. If water is present, a system of subsurface drainage is necessary, consisting of open-tile drains and broken stone or gravel on which is placed a foundation of broken stone, gravel, or cinders coated with sufficient tar to bond under light rolling.

Where the ground has sufficient natural drainage and no tile is required, the foundation course is laid directly on the ground. On this foundation is spread a layer of tarred sand in which planks are bedded by ramming and on which the hardwood wearing surface is laid and nailed. A floor of this character provides a rigid foundation for machinery and will support the heaviest materials in storage. Many of these floors are in use in mills and factories throughout New England.

The writer recently built a damp-proof floor of this kind by day labor, on which a careful record of cost was kept. The floor was laid in the basement of a manufacturing building on the natural earth, hardpan and sand, without underdrains, and carrying machinery, rapid steel in racks and square steel piled solid in storage.

The owner, wishing to secure a long-lived floor, purchased kyanized hemlock for the 3-in. underfloor and had two-ply felt and a layer of pitch placed between the plank and top flooring. The ground was prepared by the contractor for the building by rolling or puddling, therefore, the costs given in the accompanying table are for materials and labor above the ground.

The soft-coal cinders used for the foundation course were purchased from the railroad and delivered in cars on a siding from which they were shoveled directly into the basement where used. Materials were delivered and the work performed in the winter, so that storage in the basement obviated the necessity of heating the cinders when mixed with the tar. Tar was purchased from the local gas works and 13 gal. used per cu.yd. of cinders.

The cinders were spread, rolled and tamped to a thickness of 4 in., the shrinkage from measurement in cars to place was 56%. Sand and tar were heated outside the building and mixed in the basement. This mixture, while warm, was spread over the cinders and screeded off 1½ in. above the bottom of the plank; planks being laid to grade for screeding. Into the sand while still warm, the 3-in. planks were firmly bedded by ramming.

For specially prepared tars, 30 to 40 gal. per cu.yd. of sand are specified. On this work the greatest amount of tar that the sand could be made to contain, without making a soft, wet mixture, was 33 gal. per cu.yd., the same kind of tar being used in both cinders and sand. The writer has knowledge of floors where the tar has come up through the joints in both plank and top floor due, no doubt, to an excess of tar in the sand.

The difference in volume of sand in place and in carts, due to compression and to inequalities of surface of cinder layer was 45%. The plank was 3-in. kyanized hemlock, planed one side to a uniform thickness of 2¾ in. and not less than 8 in. wide, random lengths, square edged and saw butted. End to break joints and the planks were set driven tightly together. There was no loss of plank in cutting.

Over the plank were placed two layers of felt and one of pitch. The felt weighed 14 lb. per 100 sq.ft. and was laid to break joints one-half the width of the sheet; no pitch was allowed to come in contact with either plank or top floor. The loss in area of felt due to lapping was 11%.

Over the felt and at right angles to the plank was laid a maple floor 1⅛ in. thick. This flooring was square edge, 3 in. wide, and nailed with 10-penny finish nails through the top every 8 in. on alternate sides.

*18 Chapel St., Somerville, Mass.

The waste and shrinkage due partly to laying, but mostly to manufacture, was 40%; in other words, while the market price of the flooring was \$45 per M. the shrinkage in manufacturing that must be paid for, plus a small loss by waste in laying, brought the cost up to \$63 per M. Builders are familiar with shrinkages in manufactured lumber, but engineers, not having occasion to use it so frequently, are not so familiar and are surprised when as for instance, they purchase 5-in. V-sheathing for building a field office, to find that it covers a width of only 3¼ in. and that the Western rules for inspection of hard pine allow ⅛ in. less than the Eastern, which in turn allow an ⅛-in. or more, less than full dimension for square timber and plank.

Referring to the accompanying table, the quantities in Column 3 are the quantities purchased in the market, as for instance, 4 in. of cinders in place amount to 0.151 cu. yd. measured in cars, or 36% (in Column 6 of table) more than the place measurement and similarly for sand, felt and top floor, there being no loss in laying the 3-in. plank.

In this work, two distinct classes of labor or trades were employed, roofers in this case and carpenters, and though they worked together, their organizations were separate. For this reason, the combined items for superintendence is high and that for superintendence of roofers unnecessarily so. Reducing the item for superintendence of roofers and using untreated plank and leaving out the felt and pitch between plank and top floor, the cost would be reduced as shown in Column 7 of the table.

COST OF DAMP-PROOF FLOOR

1	2	3	4	5	6	7*
Materials and labor	Thickness of material in place	Quantity per sq.yd.	Unit cost	Cost per sq.yd.	Per cent of waste and shrinkage	Cost per sq.yd.

Australian Ironbark Pins in Pin-Keyed Joints

By H. D. Dewell*

The following account of the tests of two bolted and keyed timber joints using Australian ironbark (Red) may be of interest, as supplementing the tests described in Engineering News of Mar. 19, 1914.

The joints tested were as shown in Fig. 1, the pins being lathe-turned. The properties of the red Australian ironbark are given by a trade publication as follows:

	Lb. per sq.in
Modulus of rupture in bending (54x6x4 in.).........	17,600
Tensile strength	22,000
Compressive strength (12x3x3 in.)..................	9,500
Shearing strength (6x6x2 in.)......................	2,100

This wood has a straight grain, contrasting in this respect with the Hawaiian Ohia. The timber also has a much higher specific gravity than the Ohia.

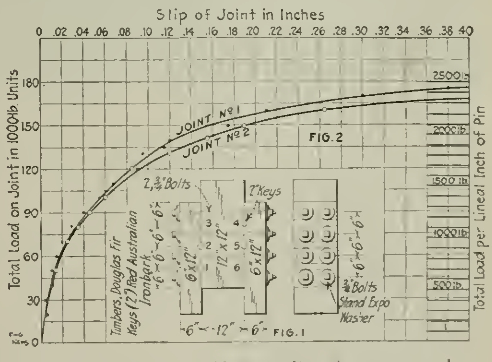
Referring to Fig. 1, pins 2 and 5 were placed with the grain vertical, pins 1, 3, 4 and 6 with the grain horizontal. The bolts were ¾ in., with standard Exposition washers (see the article above referred to). The following table gives the result of the tests:

COMPRESSION TESTS OF TWO PIN-KEYED JOINTS WITH IRONBARK PINS

(Six 2-in. pins 12 long, per joint.)

Load thousand lb.	Slip, in inches: Splice A	Splice B	Average	Remarks
JOINT 1				
10	0.0	0.0	0.0	
20	0.01	0.0	0.005	
110	0.08	0.06	0.070	
120	0.10	0.08	0.090	
130	0.11	0.08	0.095	Pin 2 slight crack
140	0.12	0.12	0.120	Pin 5 slight crack
170	0.30	0.30	0.300	Pin 1 slight crack
180	0.58	0.58	0.580	Max. load.
Load JOINT 2				
30	0.01	0.0	0.005	
40	0.02	0.0	0.010	
50	0.03	0.0	0.015	
140	0.20	0.11	0.155	
150	0.23	0.15	0.190	
160	0.31	0.22	0.265	Pin 2 cracked
168 (Max.	0.58	0.49	0.585	Pin 2 sheared

Fig. 2 shows the load-deformation curves. While the curves show no very definite yield-points, the values of 1875 lb. and 1600 lb. per lin.in. of pin have been taken as representing the elastic limit of the two joints. The



Pin-Keyed Joints for Test of Red Australian Ironbark Pins, and Curves of Results

working value of these pins in design was taken at 800 lb. per lin.in. of pin, representing a factor of safety of 2 on the yield-point.

The failure of the joints was due primarily to the crushing of the Douglas fir. While both the maximum load and the yield-point load per unit length of pin were less than those shown in the Ohia pins (6 in. long) of the previous tests, an extended series of tests alone would determine the relative efficiency of the two timbers.

The above tests were made for the Panama-Pacific International Exposition by the civil-engineering laboratory of the University of California and were used in connection with the framing of the timber portion of the Main Entrance Tower.

*Chief Structural Engineer, Panama-Pacific Exposition, San Francisco, Calif.

Chicago Bridge Work by Day Labor

By Harry J. McD[illegible]*

SYNOPSIS—The employment of the day-labor system for municipal construction work is on the increase, and in Chicago this system has been adopted with success on extensive sewer work and some bridge work, while it has been decided to adopt it also for one of the new waterworks tunnels. The following article describes the construction of seven fixed bridges over the north branch of the Chicago River by day labor.

During the year 1913, the city of Chicago constructed several fixed bridges by day labor. The term "fixed bridge" is used by the city to designate all types of bridges other than those constructed over the navigable parts of the Chicago River. There are seven fixed bridges over the west fork of the North Branch of the Chicago River within a distance of four miles, and this article relates to the construction of these bridges at their respective locations by the use of day labor. Fig. 1 is a view of the Central Park Ave. bridge.

The bridges are all similar for one of the locations, and are of the plate-girder deck type with concrete substructures. Excavation for the substructures was made through loam, gravel and stiff blue clay to a depth of at least 8½ ft. below low water to allow for a possible future dredging of this stream.

The superstructure design is shown in Fig. 2. The main girders are 73 ft. 8 in. long, with the floor system designed to carry the heaviest city traffic. The roadway is 24 ft. between curbs, paved with 4-in. creosoted-wood blocks on 3-in. creosoted subplanking laid tight on 4x6-in. creosoted stringers spaced 1 ft. [illegible] in. c. to c. The two 8-ft. walks are of reinforced-concrete flat-slab construction. The sidewalk railing on the bridge is of ornamental cast construction, and joins the concrete parapet walls carried on the wing walls of the substructure.

The wing walls of the substructure end in a circular return and come to within 2 ft. of the property line. All streets are 66 ft. wide. The esthetic treatment of both the substructure and superstructure was recommended by the Chicago Plan Commission, and the resulting structure is quite effective in appearance, as shown in Fig. 1.

The Commissioner of Public Works* is the executive head of the city of Chicago for work of this class. The City Engineer† is the executive of the Bureau of Engineering, and one of its departments is the Division of Bridges and Harbor,‡ under which division this work was done. The field organization consisted of an engineer (the writer) acting as general superintendent; an instrument man as timekeeper and material clerk; a foreman of carpenters, cement mixers and laborers and in charge of substructure construction, and a foreman of bridge and structural-iron workers in charge of erection of the superstructure. The rates of wages per hour (union scale) were 80c. for foremen, 72½c. for hoisting engineman, 65c. for carpenters, and 40c. for laborers.

Contracts were made in the usual manner for furnishing and delivering the superstructure steel and creosoted

FIG. 1. BRIDGE AT CENTRAL PARK AVE., WEST FORK OF THE NORTH BRANCH OF THE CHICAGO RIVER

(Typical of seven bridges built by day labor under the Department of Public Works, Chicago)

lumber at each bridge site. Steel, stone, gravel, cement, reinforcing steel and lumber were delivered to the bridges under requisition made on the city's yearly contract for these supplies. Smaller supplies, such as nails, wire, bolts, etc., were secured through the city purchasing agent.

Material costs under the contracts were as follows: cement, $1.[illegible] per bbl. net; torpedo sand, $1.70 per cu.yd.; stone or gravel, $1.65 per cu.yd.; lumber (average) $[illegible] per M ft. b.m.; superstructure steel, 2.01c. per lb. An additional charge of 3c. per bbl. on cement and 10c. per cu.yd. on sand, stone, or gravel was made for each mile or fraction thereof beyond a defined territory.

The plant consisted of a 10-ton stiff-leg derrick with a 50-ft. boom, a 16-hp. steam-hoisting engine, four 1-yd. self-dumping steel buckets, a steam pump, a gasoline-driven concrete mixer of 8-ft. batch capacity, and the other necessary smaller equipment.

The average depth of excavation was 16 ft. below the curb grade, and each pit was sheathed tight to blue clay, due to the water-bearing gravel and the proximity to the river. No extraordinary conditions were encountered. Excavation of the blue clay was laborious, however, as

*Assistant Engineer, Department of Public Works, Chicago.

*L. E. McGann, Commissioner of Public Works.
†John Ericson, City Engineer.
‡Thos. G. Pihlfeldt, Engineer of Bridges and Harbor.

it could only be loosened in small chunks by the use of mattocks. Keeping the clay water-soaked was found advisable.

Cost and Progress of Work

The substructures at N. 40th Ave. and N. 48th Ave. were started during the fall of 1912, but all work was suspended before the end of the year. Work was again started May 9, 1913, and three other substructures (at Central Park Ave., Kedzie Ave. and 56th Ave.) were completed during the year. The substructure at Forest Glen Ave. was 90% completed on Dec. 31, and was entirely completed Jan. 29, 1914.

The superstructure steel for N. 40th Ave. was delivered on the site July 2, the erection completed Aug. 12 and the roadway opened to traffic Sept. 1. Erection of 48th Ave. superstructure was started July 31, completed Sept. 3, and the roadway opened to traffic on Oct. 1.

The next superstructure steel arrived Oct. 21, and was erected at Central Park Ave. and this bridge opened to traffic on Dec. 20.

The steel for the Kedzie Ave. superstructure arrived on Dec. 4, erection was completed Dec. 27, and the roadway opened to traffic Feb. 14, 1914. Erection of the superstructure at 56th Ave. was started Dec. 29, completed Jan. 28, and the roadway opened to traffic Feb. 26. At Forest Glen Ave. the delivery of the steel was started Feb. 9, but was tied up until Feb. 20 by a strike on the company furnishing the material. Erection was completed Mar. 12, and the roadway opened to traffic on Apr. 7, 1914.

The old structure at Kedzie Ave. was a wrought-iron through-truss bridge, 63 ft. long and 36 ft. wide over all, that had been used at another location. This truss was "house moved" to Foster Ave. and erected on timber bents set on concrete foundations. Its present location is an unimportant thoroughfare and it is expected that it will serve 10 yr. or more at this, its third place of usefulness. While being moved, the truss was carried on two sets of 12x12-in. timbers, 6 ft. c. to c., placed symmetrically to the center of the bridge. Using wood rollers on a timber runway and a crab, this 35-ton truss was moved 1300 ft. and set up on bents for $383.50.

For excavation, backfill, coffer-dam, sheathing and pumping, the cost on the several jobs varied from $1.23 to $1.55 per cu.yd. The substructure concrete (1:3:6) varied in cost as follows:

Labor for handling sand, stone and cement to mixer, mixing and placing in forms, $1.291 to $1.108 per cu.yd. Part of this variance in the cost of labor was due to the uneconomical method necessary in handling the material, as it was compulsory to keep the narrow roadways open and the material was scattered along the side of the road for a distance of 600 ft. from the bridge on each side of the river.

Material cost $3.778 to $4.558 per cu.yd. of concrete. This variance was due to difference in length of haul for delivery.

Forms, including labor and material, cost $1.580 to $1.986 per cu.yd. of concrete.

The erection of the steelwork was done without the aid of power machinery and all riveting was by hand. The cost varied from 0.75 to 0.77c. per lb.

The creosoted wood-block pavement with sub-planking and sleepers cost for material $4 per sq.yd.; the labor for placing averaged 81½c. per sq.yd. for roadways without car tracks and $1.40 on the roadway with car tracks.

The widths of the roadways leading to the bridges were in most cases about 18 ft. and these were widened to meet the approaches of the new bridge at a cost varying from 74.7 to 95.1c. per cu.yd.

Advantages of Day-Labor Work

It is only natural to inquire as to the advantage of doing this class of municipal construction work by day labor. The two important elements to consider are time and cost.

The old adage that "large bodies move slowly" is applicable to any corporation of the size of the city of Chicago. This is as it should be, for it is absolutely necessary that every precaution be taken to safeguard the city's interest by each of the several different departments having jurisdiction in the making of contracts. In contract work, considerable time elapses between preparing the plans and specifications, awarding the contract and starting the work, due to the different steps and procedures. A great portion of this work and time is saved with the day-labor system as the Commissioner of Public Works instructs the City Engineer to proceed with certain work, and the latter similarly instructs the Engineer of Bridges and Harbor, so that within a short time substructure work can be started. At the same time, detailed plans and specifications can be prepared and a contract entered into for furnishing the superstructure, which (with an ordinary condition of the steel market) can be obtained by the time it is needed.

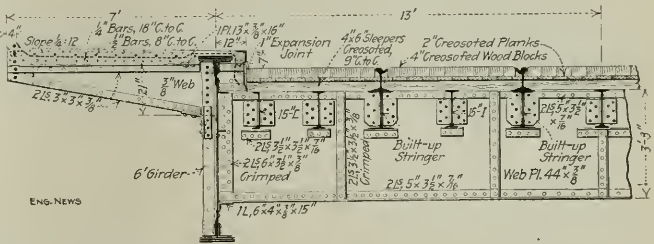


Fig. 2. Half Cross-Section of Plate-Girder Bridges over the West Fork of the North Branch of the Chicago River

It is not uncommon for the low bidder on some new work to be busily occupied with his equipment in an attempt to finish other contracts. This condition is the cause of a continuous fight on the part of city officials in an attempt to get the contractor to start the new work with such an organization as will guarantee the completion at the time specified. With the work being done by the city direct, the man in charge realizes that his own welfare is at stake if the proper progress is not made.

The cost of supervision in day-labor work is eliminated. The engineer and instrument man in charge of day-labor work would have the same relative positions in contract work. The two inspectors on contract work who supervise the proportioning of the concrete aggregates and the

placing of the same are eliminated. Also the inspectors on the erection of the steelwork and the laying of the roadway and sidewalk pavements.

Another source of saving is the middleman's profit in handling the superstructure material. Another advantage as regards cost is due to the fact that when contracts are let for small jobs of this size, the low bidder is frequently a small contractor poorly equipped or new at the business, and although the city may get the benefit of a low bid, the contractor is working at a disadvantage and if at a small margin of profit, his whole aim is to work as cheaply as possible, and little attention is paid to the time it takes him to complete the work. This results in a general dissatisfaction to those living adjacent to the work and an increase in the cost of supervision.

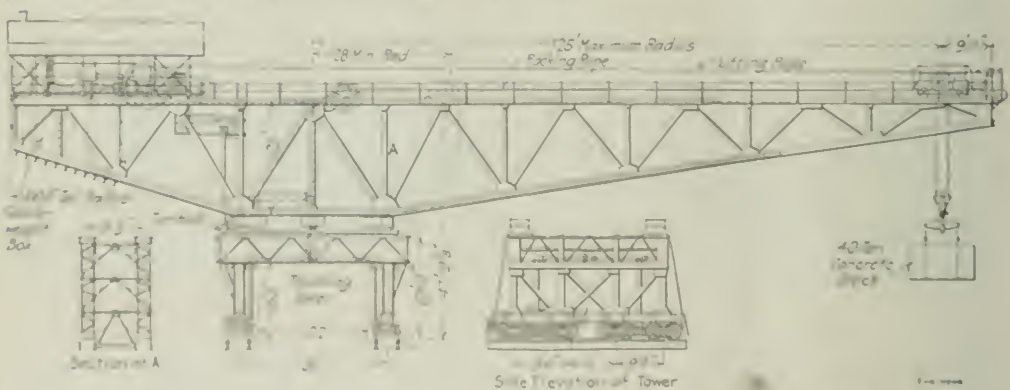
Anyone connected with municipal contract work appreciates the dread of having to encounter extras. In day-labor work, there is no worry about extras. Even with the utmost precaution in preparation of plans and specifications, unforeseen conditions frequently arise and upset the best calculations. Operation under day labor permits changes to be made during construction, when the necessity occurs, without the accompanying troublesome negotiations required on contract work.

There is one important condition absolutely necessary to successful prosecution of this class of work and it is the willingness to retain only such men on the payroll as are capable of doing justice to the work assigned them. In this respect, the writer cannot give too much credit to his superiors for their support. There is an idea that municipal employees are not compelled to render equal service to that required by a contractor. When such a condition is found, it is due usually to the man in charge. The writer has not [illegible] to have an inefficient man [illegible] on the payroll but was expected to dismiss all such men immediately.

Revolving Cantilever Crane for Harbor Construction Work

The revolving and traveling cantilever crane shown in the accompanying cut belongs to a type of machine used very extensively by English engineers and contractors in the construction of breakwaters and other harbor work in various parts of the world.

This crane has a pair of trusses 11 ft. 3 in. apart, 185 ft. 6 in. long, with a working arm of 125 ft. and a tail or counterweight arm of 60 ft. 6 in., the latter carrying the engines and boiler and a counterweight box. The trusses are mounted on a live-ring turntable 31 ft. diameter on the top of a tower consisting of a heavy girder frame on a pair of side trusses. The crane travels on two tracks of standard gage, spaced 30 ft. c. to c., but instead of single rails for the tracks there are double rails carrying 36-in. wheels which have wide flat tires with central flanges riding between the rails. There are four four-wheeled trucks on each track, or 32 wheels in all. Each pair of rails is secured to a bed-plate on a pair of I-beams.



Traveling and Revolving Cantilever Crane for Setting Concrete Blocks on Harbor Work at Fishguard, England

(Stothert & Pitt, Builders, Bath, England)

The main engine has cylinders 11x18 in. It operates the hoisting cable, the cable for racking the trolley along the boom, the swinging gear and the propelling gear. The latter consists of bevel-gear drives to four countershafts (between the trucks), from which the axles are driven by chains. It has an 8-part hoisting tackle, with a vertical travel of 60 ft., and can hoist 40 tons at 8½ ft. or 7 tons at 18 ft. per min. The trolley has a travel of 97 ft., and can run at 22 ft. or 45 ft. per min. with the above loads. The crane can travel at 32 ft. per min. with a 40-ton load, and can make a complete revolution in three minutes. The box in the short arm contains about 100 tons of pig iron for a counterweight.

This crane is to be used in setting stone and concrete blocks for the harbor work of the Great Western Ry. at Fishguard, on the Welsh coast, for which Topham, Jones & Railton are the contractors. It was built by Stothert & Pitt, of Bath, England, and was tested with 50-ton loads after completion.

Our information and drawing are from *The Engineer*, of London.

The Lime Product of the United States in 1913 was [illegible]

Some Remarkable Photographs of a Large Blast

The accompanying five illustrations show in a remarkable manner the progress of a large blast of 125 tons of black powder. The illustrations on the right are taken from one side of the hill to be removed and the two lower pictures on the left are taken from the opposite side.

The upper picture represents the ground surface before the explosion. The second picture was taken at the instant of the explosion, before the explosive gases had fully commenced to break through the earth crust. The third picture on the right shows the broken surface after the blast. The two lower pictures are self-explanatory and give a very fair idea of the amount of rock removed.

The blast was a part of the construction work on the Prince Rupert, B. C., terminal of the Grand Trunk Pacific Ry., done last winter by Foley, Welch & Stewart, Contractors, of St. Paul, Minn., and Vancouver, B. C. For the photographs we are indebted to Wm. T. Donnelly, Consulting Engineer, New York City, who is building a large dry dock at Prince Rupert, a description of which was given in ENGINEERING NEWS, Jan. 4, 1912, p. 1.

The general character of the shore of Prince Rupert is bold and rocky and the railway entrance required some heavy grading. The Grand Trunk Pacific Ry. reaches the coast by the Skeena River valley, about 15 miles to the south, and, crossing to Kaien Island, where is located Prince Rupert, at its southern end, closely follows the shore to and along the water front of the city. Where four years ago was a complete wilderness is now a thriving city and seaport of several thousand inhabitants and many business institutions.

The Hydraulic Dredge "Niagara" and Its Work in the Saginaw River

One of the heaviest and most powerful hydraulic dredges of moderate size is the "Niagara" designed primarily for work in the hard material beneath the Saginaw River between Bay City and Saginaw, Mich.

dredging equipment, which was developed by the Bucyrus Co. The hull (built by the Manitowoc Ship Building and Dry Dock Co.) and other machinery, is of interest secondarily.

The cutter head (Fig. 3) is unusual. It is a six-bladed type 100-in. diameter, and of nickel-chrome steel. The blades carry socket-fitted teeth, three on one blade and four on the next. The cutter shaft is 11½ in. in diameter at the cutter end and 10 in. at the other. The gearing at the top of the dredging arm is mounted on a cast-steel bedplate for rigidity. The suction arm is a 77,000-lb. plate girder (see Fig. 1). The A-frame, braced beams, etc., have all been made correspondingly heavy. The pump is extra heavy (of nickel-chrome steel) weighing 71,000 lb. exclusive of engine. The casing is unlined. The engine is a 1000-hp. triple-expansion marine type

Fig. 1. Forward End of Dredge "Niagara"

This work is being done by the U. S. War Department and contract was let to G. H. Breymann & Bro. of Toledo. One of the two sections was sublet to the Duluth-Superior Dredging Co., of Duluth, owners of the "Niagara."

The channel which is being improved extends from the 18-ft. curve in Saginaw Bay to the junction of the Tittabawassee and Shiawassee Rivers, a distance of 21½ miles. This channel is to be 200 ft. wide at the bottom and 18 ft. in depth. The total excavation amounts to over 4,000,000 cubic yards, of which [illegible] cu.yd. is included in Section 1 which Breymann Bros. did [illegible] of the work with [illegible] dredges [illegible] that part of the channel from Bay City to Saginaw Bay. The Duluth-Superior Dredging Co. is working two 20-in. hydraulic dredges, the "Niagara" mentioned before and the [illegible]. The former is being used on the hard material at the lower end of [illegible] and the latter [illegible] Saginaw, working from the middle [illegible] toward the upper end of the section.

The material encountered in Section 2 consists largely of sand and clay for a distance of about [illegible] miles. For the remaining [illegible] miles it is very hard [illegible] clay, or hardpan, with a large quantity of stones of various sizes. Therefore the "Niagara" was designed for digging this material and the construction and [illegible] provided with [illegible]

The greatest interest in the "Niagara" lies in its

Fig. 2. After End of Dredge "Niagara"

(built by Marine Iron Works of Chicago); it has a speed of 200 r.p.m. and can pump the dredged material through a 5000-ft. pipe line 10 ft. above water.

The cutter engine is a double-cylinder 12x15-in. type of heavy construction for 200-lb. boiler-gage pressure. The cutter gears are large and extra heavy. The spuds (Fig. 2) are of ¾-in. steel pipe, lap-welded, 39½ in. in diameter and 67 ft. long. They carry cast-steel points.

The hull is 135 ft. long and 11 ft. deep, with 43-ft. beam. There are two longitudinal bulkheads from end to end and three transverse. Coal bunkers are in the side compartments below deck and abreast of the boilers. To minimize vibrations, the engine and pump foundations are built on high floors across the hull. The ladder well forward is made of ⅝-in. shell plate and heavily braced. Trolleys over the engine and pump facilitate inspection and repair. Over the machinery and boilers is a two-story steel deck house. The lower house has the kitchen, dining room and crew's washroom. The upper house has the officers' washroom and bath and sleeping quarters for 36 men. The operating room is forward and elevated; the many large windows give the operator unobstructed view of the work.

The general plan of operation is similar to any other hydraulic dredging job. The material excavated from the channel is pumped on to the bank of the river to form a levee upon which is to be built a road connecting the cities of Saginaw and Bay City.

The "Niagara" started digging June 5, 1913, and dug until it was laid up for the winter on Dec. 23. During this period it worked 3018½ hr., and was delayed for various reasons, 1008½ hr. All but 193 hr. of the time charged to delays was consumed in shifting pipe lines and in the other normal operations which necessitate stopping the pump. Of this 193 hr., the major portion was due to the wearing out of the pump casing and parts

Fig. 3. Cutter Head of Dredge "Niagara"

of the suction and discharge pipes which pass through the hull, due to the unusually hard character of material pumped.

During this working season, the dredge excavated a channel 14,600 ft. long to a depth of about 17.5 ft., with an average width of 235 ft. The maximum depth of cutting was 7.4 ft., and the total amount of material removed, 910,000 cu.yd., of which 730,323 was pay material, the remainder being taken outside of specified channel lines.

The dredge "Enterprise" dug 940,000 cu.yd. between Apr. 22 and Dec. 13.

Washington, D. C., Street-Cleaning Methods

By J. W. Paxton*

SYNOPSIS—This is the third of the series of articles describing Washington municipal street-cleaning methods. The previous articles appeared in Engineering News *of July 9 and Aug. 6. This article describes the office methods of planning and keeping in touch with the field work.*

Office Methods

Unit of Work Done—In order to obtain unit costs, it was necessary that a measure of the street-cleaning work done should be established. It was hoped that a unit could be found in which elements of the area swept, amount of dirt collected, length of haul, etc., would be combined in a proper proportion, but this still seems impracticable.

Former contractors were paid by the 1000 sq.yd., and as this unit was generally used elsewhere, it was thought advisable to adopt it for purposes of comparison. However, suburban street cleaning more than any other, brings out the faults of such a unit based on area alone. When a street is very dirty or washouts occur, most of the effort is expended in loading and hauling, and at times only 1000 or 2000 sq.yd. are cleaned per day, while under favorable conditions the area may run as high as 50,000 sq.yd.

Street Intersections—Formerly in making payment to the contractor, it was necessary to have accurate and official information of the areas of streets and alleys, which was obtained from the Surface Division of the Engineer Department. For purposes of computation, it was necessary to divide the area of each street into small sections, the most convenient being the areas between cross streets and the intersections common to two or more streets (Fig. 1). This information, together with the kind of pavement, is arranged on white cards 5x8 in. in size, ruled for four rows of three columns each; the column heads are "limits," "area" and "pavement" (kind of).

Street intersections carry the traffic from at least two

*Superintendent of Street Cleaning, Washington, D. C.

FIG. 4. PART OF A SURFACE DIVISION MAP, SHOWING METHOD OF DIVIDING STREETS INTO STREET CLEANING AREAS

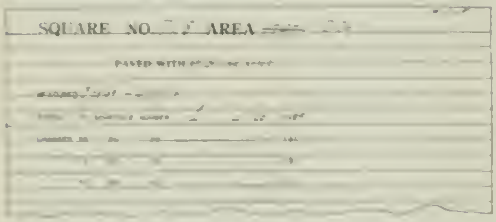


FIG. 5. FRONT FACE OF ALLEY CARD

[illegible] it is reasonable to suppose that they need twice the amount of cleaning. As a matter of fact, they are cleaned twice as often as the remaining portions [illegible] in showing the area cleaned, they are so credited.

ALLEY MEASUREMENTS—For alley measurements, a 3x5-in. index card has been arranged, which shows on the face, the square number, area and kind of pavement, date measured, and the number of the schedule on which the alley in each square appears (Fig. 5). On the reverse side is a sketch of the alley (Fig. 6). This sketch is not drawn to scale but is valuable in showing exactly what is included in the measurement given.

FIG. 7. [illegible]

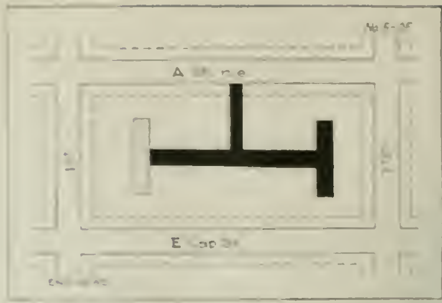

FIG. 6. REVERSE SIDE OF ALLEY CARD

In many cases, a number of private alleys open on a general public alley, but are not cleaned. From time to time, these private alleys are made public and they are added to the schedule. In the illustration shown, the area originally cleaned is solid; the cross-sectioned portion was condemned and added to the schedule nearly four years later, so the face of the card shows both the original and new areas.

SCHEDULES—Each foreman, other than those of the hand patrol and alley gangs, is furnished with a schedule (Fig. 7), printed on green paper 8½x14 in., on which the areas of the streets are printed. The foreman checks off the portions of the streets as they are cleaned, fills in the spaces for information in regard to equipment, quantities of dirt removed and water used and returns the schedule to the office, where the total area is figured and credited to his gang.

It is not practicable to print the schedules in the order in which the streets are to be cleaned, as delays for any reason would disarrange any regular route. Regular intervals must exist, however, as far as possible, between the cleaning of each street.

The schedules for alley cleaning differ from those for surface-street cleaning, only in the fact that they are printed on white paper and the square numbers and boundaries replace the names of the streets. The squares are arranged in [illegible], and must be cleaned in the given order. The [illegible] area is entirely cleaned each day, so no schedules are required.

Schedules are made up in the office, [illegible] covered with sheet celluloid, [illegible] and then printed on a [illegible]. Of the final maps which result from this study, one is kept of the hand-patrol areas and [illegible], one of all machine-broom and flushing territory, a third of the suburban and [illegible] territory, and a fourth of the alleys. A [illegible] map is also kept on which the kind of sweeping given each street is shown at a glance.

All schedules are considered as orders to the foreman. If temporary or permanent changes are to be made, a [illegible] form, properly filled in describing these changes, signed by the Superintendent or one of his assistants, is issued to the foreman, who uses this form as his authority until [illegible], or until new schedules are issued on which the correction has been made.

GARBAGE RECORDS—Information is often desirable as to the dates on which certain streets or alleys have been

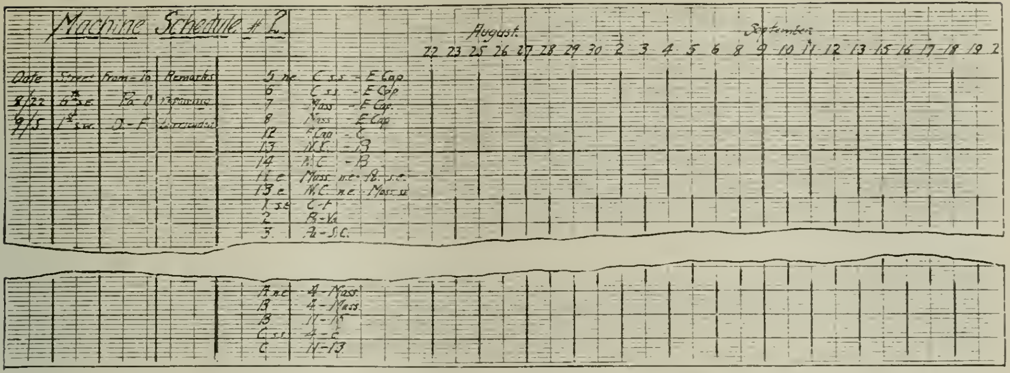

FIG. 5. GRAPHICAL METHOD OF KEEPING TRACK OF STREETS CLEANED, AND OF SEEING THAT SCHEDULED ATTENTION IS GIVEN TO EACH

cleaned, or streets washed or oiled. Previously this necessitated a long search of old schedules, but a simple graphical method of keeping this record has been devised, which is also useful in showing at a glance whether streets have received regular attention for extended periods.

On the machine schedule (Fig. 4), Second St., S. E. from Pennsylvania Ave. to Virginia Ave. is checked, indicating that it was cleaned on Sept. 5. This is shown in the graphical method devised to keep track of streets cleaned (Fig. 5) by a vertical line opposite the street and under that date. From machine schedules of other dates, similar information is plotted, showing this street was also cleaned Sept. 8, 10, 12 and 15. One such plot is kept for each street-cleaning gang, whether machines, alley, suburban, or washing; each plot usually running for three months.

Apparent errors on the part of the foremen in checking streets cleaned are very likely to be caught up in making this profile. A printed correction slip has been adopted to call to the attention of the field force any such errors which may appear, this slip being made up by the clerk who keeps the profile, and it is sent out to the foreman who then writes an explanation on the slip and returns it to the office.

The area cleaned, dirt removed, equipment employed and water used, as reported on these schedules, is posted daily on the Work Summary Sheet (Fig. 6). From the Time Reports (described in the article in ENGINEERING NEWS, July 9, 1914), the number of men employed and the hours worked are obtained semimonthly and this information likewise entered on the form, Fig. 6, giving a complete record of the physical work performed, etc. The hand-cleaning foremen, not having schedules, the dirt collected is reported by them on the Sack Report (Fig. 7).

FIG. 7. REPORT OF DIRT COLLECTED ON HAND PATROL

One-Inch Sheet Asphalt on a Concrete Base—The California State Highway Department is surfacing a part of the main coast road south from San Francisco with 1-in. of sheet asphalt laid on a 5-in portland cement concrete base. This section of road is in the suburbs of San Francisco and is designed to carry a moderately heavy city street traffic, about 75% of which is motor vehicles. The old roadway was built of waterbound macadam, 12 ft. wide and 6 to 12 in. deep. The new pavement is 24 ft. wide with 8-ft. earth shoulders. The maximum gradient is 4%. The foundation is 1:3:6 concrete; after the foundation is thoroughly set it is painted with a hot liquid asphalt mixture composed of one part by volume of asphaltic cement to two parts of engine distillate. The asphaltic cement is first heated to about 325° F., and when it is cooled to 250° F. the distillate is added and mixed in. This mixture is poured on the concrete surface from buckets. The consistency of the paint coat is made to vary with the porosity of the concrete surface. On this binder coat is laid the 1-in. course of asphalt mixture composed of sand, limestone dust and asphaltic cement. This is heated and put on at a temperature as close to 325° F. as possible. The very thin layer cools so rapidly that it is necessary to follow the hot hand rollers with a 5-ton or 8-ton steam-roller just as soon as can be done. The binder paint coat was a late addition to the specifications. It was found that the 1-in. surface on the asphaltic paint binder moved or melted very little under the roller as compared with that laid directly on the dry concrete. Although the economy of this type of construction is yet to be proved it has thus far given every assurance of being well adapted to conditions. [Information taken from an article by E. B. Rine in the "Iowa Engineer."]

Construction Camp for the Town of Torrance, Calif.

By Ralph Bennett*

In the construction of localized works of considerable magnitude, such as long tunnels, power houses, dams and similar structures remote from cities of considerable size, it is necessary for the employer to make provision on a considerable scale for the relatively permanent residence of large numbers of men. These towns, or camps as they are commonly called, should be as inexpensive as is consistent with proper housing.

A camp, whether temporary or permanent, should be located on gently sloping ground which will provide satisfactory drainage.

The most important requisite is water. Provision should be made for securing a supply which will be ample and uncontaminated during the entire duration of the work. Water should come to the camp under sufficient pressure for ordinary tank use and should be supplied through pipes 3 or 4 in. in diameter so that one or two fair-sized fire streams can be used. There should be a 2-in. hose outlet with 100 ft. of $1\frac{1}{2}$-in. cotton factory fire hose located to cover every building.

As a matter of fire protection, as well as of convenience, all buildings should be wired for electric lights, and the use of lanterns should be restricted to those classes of work which require portable outdoor lights.

*Consulting Engineer, Los Angeles, Calif.

Fig. 1. General Layout of Construction Camp for Town of Torrance, Calif.

Tents are not of sufficient durability and do not afford a comfortable enough shelter for use except in summer camps. The construction for permanent camps need not necessarily be of heavy material. It should in fact be of as light material as is consistent with necessary rigidity. The buildings should be of cheap lumber and should involve the least possible amount of labor. The salvage material should be of value for other work.

The accompanying illustrations show a series of buildings designed by the writer for the use of the Dominguez Land Corporation's employees in the construction of the town of Torrance (see Fig. 1 for general layout).* The buildings are intended to be occupied intermittently during a period of several years by a force of from 40 to 100 men. Their construction is believed to contain some features of merit. The designs involve the use, without cutting, of stock sizes of material for nearly all portions of the buildings.

The structures composing a permanent camp are usually a cook house, dining room, one or more bunk houses, a stable for horses and a commissary or company store. To these there is frequently added a wash house and sometimes a number of cottages for married men.

Cook House and Dining Room—In the cook house, the item of most particular interest is the roof and window arrangement. A shed roof is considerably cheaper to build than any other style. In the design shown (Fig. 2), necessary stiffness is secured for both the roof and the building by the use of a simple nailed truss under every rafter. The window openings are practically continuous, are screened on the outside and have the sash mounted against the inside of the boarding without frames. These sashes can be leaned back during the summer or pulled up to close the openings, as the climate warrants. This side of the cook house should preferably face the east or northeast in order to obtain the early morning sunlight without becoming overheated during the afternoon. The high windows furnish an even light on all tables and produce satisfactory ventilation with but little draft. In a cook house larger than the one shown there should be a door opposite each runway. All doors must be of ample size and arranged to swing out. All openings must be screened.

*Previous articles on this new town may be found in "Engineering News" of Oct. 16 and Dec. [illegible], 1913, and Jan. [illegible], 1914, the latter under the title "[illegible] Methods in Locating and Planning a New Town."—Ed.

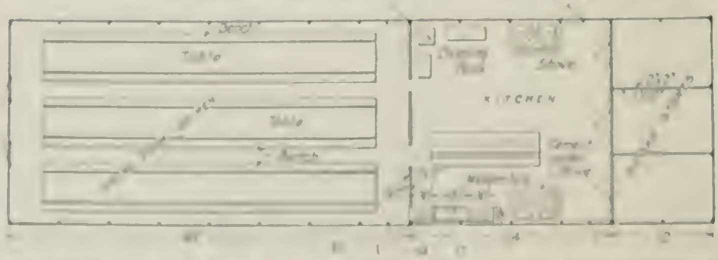

Fig. 2. Cook House and Dining Room, Torrance Construction Camp

The main stove should be of ample size and should be set on a concrete or brick or rock base large enough to be safe from accidental ignition. Distillate-burning stoves are now universally used on the Pacific Coast. They are more economical, even in the woods, than wood or

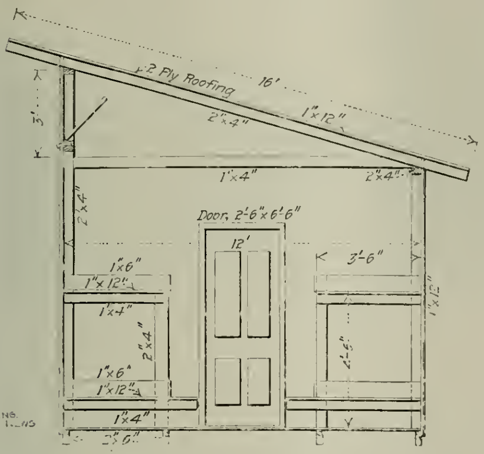

Fig. 3. Cross-Section of Bunk House, Torrance Construction Camp

coal stoves, the fire produces a better heat and the cooking is more even. The stove should have a water-back with large storage-tank.

The larger the sink and drainboard the less trouble there is in retaining flunkeys. The tables should be covered with white oilcloth. White enamel ware appears to give better service than any other style of table furnishing. Benches and tables should be substantial. The tables should be 4 ft. wide. This class of furniture is thoroughly satisfactory for camp use.

If, as is now frequently the case, the management provides and occasional lecture or moving-picture show, this, high-ceiling room is quite satisfactory.

Bunk House—The bunk house (Fig. 3) is in its general arrangement typical of a large number of bunk houses in use in California. The use of a shed roof with high windows furnishes better light and air than does the old-style peak roof. In this particular house the bunks are unusually commodious and are provided with a continuous seat alongside of each lower bunk in preference to a single central bench. Steel bunks are sometimes substituted for the wooden frames. They have the advantage of being vermin-proof, but the disadvantage of leaking loose straw and other material more or less continuously. Except in very severe climates, no stove should be permitted in a bunk house. If there is a very considerable number of employees, the construction of a number of medium-sized bunk houses is much to be preferred to the use of a single large building. The loss in case of fire is less and the men are better satisfied in that they can separate by nationalities and trades.

Certain classes of employees, such as cooks, stable men, foremen and superintendents, require separate houses in any case. Shed-roof buildings of the same type can be used but subdivided crosswise into the necessary number of apartments.

Loafing Room, Bath and Wash Room—A combined loafing room, bath and wash room should be constructed in a camp housing less than 100 men. In larger camps these can be separated to advantage. The stove here should have a water-back to supply water for the shower baths and for washing the mens' clothing. There should be with it a tank of very considerable size. If the employer furnishes small wash tubs in place of the traditional 5-gal. oil cans, the men will appreciate them. For washing the face and hands, there should be a row of faucets located out of doors in the sun above a wooden trough equipped with graniteware wash basins.

Sanitation—The sanitation of the camp and minor policing should be in charge of a sweeper or sweepers who would clean up daily, supply necessary wood and start the wash-house fire before the end of the day. He should keep all buildings locked during the day and when unoccupied.

Ample supplies of disinfectant should be allowed and there should be a periodical whitewashing of the entire property.

Night shift employees should be, so far as is possible, segregated into a separate bunk house.

Water closets equipped with first-class plumbing should be installed in any camp where the duration of the work will warrant it. They are more sanitary and agreeable in every way than the best possible sinks, and have the very great advantage that they can be so screened as to minimize the possibility of fly-transmitted infection.

The most serious foe of health in the camp is the fly. Flies live on garbage and breed in manure. Manure should be hauled away daily and garbage should be kept covered. A number of fly-traps similar to the one shown by Fig. 4 should be located around the camp and emptied very frequently. The trapped flies can be stunned by dashing distillate or gasoline into the cage and can then be shaken out and burned.

Stables—A camp of any size employs a large number of horses and they, with their feed and equipment, occupy a stable of considerable magnitude. The preferred arrangement of camp stables places the mangers lengthwise of the center line with the feed on one side and the animals on the other. Center-post construction will be

Fig. 4. Fly Trap for Construction Camp

more economical here than a single-span shed roof. If the stalls are on the south side of the building and are somewhat sheltered from the prevailing wind, that side of the stable can be left almost entirely open. The depth back of the animals should be ample for a convenient

runway. The harness of work animals is almost always hung on a bracket opposite the animal, but there should be a locked harness room for storing and repairing spare equipment. The bigger the corral and the more use there is made of it, the less trouble there is in maintaining the health of the animals. A great many horse diseases are communicated by dirty water in drinking troughs. Series troughs should not be used on account of this possibility. Small short individually filled troughs emptied and cleaned daily are much to be preferred.

Most of the miscellaneous wagons used by a modern camp are of the type known as heavy farm wagons. These can now be had all steel with roller bearings at a less price than in any other form and require not over two-thirds as much tractive power and require but very little maintenance or upkeep.

Gasoline Tractors for Southern Road Work

By G. B. Buchanan*

While gasoline power has been in use on Northern and mid-Western road work for several years, its introduction into the Southern States, and especially the southeastern tier of coastal states is very recent. One of the first tractors to be purchased by a county for use on the roads of Virginia was bought by Caroline County last year. Some observations of its work, cost and economy should interest road builders in other parts of the South.

Conditions of Work—A tractor for use on Southern roads must have a broad range of uses. County road work heretofore has been done generally in a crude, slipshod way, with mule teams and hand labor. The roads are narrow, curves sharp and grades steep. There are few culverts, and in many cases the bridges are too weak to carry tractors. Many portions of the roads run through timber so that any effort to widen them necessitates much clearing.

Type of Tractor—Several designs of tractor were investigated, but the type finally selected was a combination kerosene-gasoline, 50-25-hp. tractor made by the Ohio Tractor Co., of Marion, Ohio, costing $3000. A 25-15-hp. tractor was first received and tried out, but its drawbar pull was found too light for the heavy grades encountered—often 8 to 10%—and, also, the loose sand of the river valleys made it impossible to move the tractor with the extra weight put on the frame for rolling purposes. As stated above, conditions in the South Atlantic States differ from conditions in the mid-Western prairie sections, for which the gasoline tractor apparently was designed.

While the tractor developing 25 hp. on belt and 15 hp. on drawbar pull met requirements as a roller and tractor for light pulling, it was seen that there would be so little rolling done and so much heavy pulling needed that the 50-25-hp. engine would be more suited to the present needs of the county. Developments have fully justified the selection made.

The motor is an opposed-cylinder, heavy-duty type, burning kerosene in several grades, or gasoline. It has been found that more tractive power is developed on gasoline. While this costs more, it has been proved that 1 bbl. of gasoline will last as long as $1\frac{1}{4}$ bbl. of kerosene, as well as produce more power. The conditions being such that there is no way of telling what kind of work will develop during the day's progress it has seemed better to burn gasoline. The fuel tank holds a full barrel, which has lasted variously from 7 to 10 hr., running on heavy to light work.

Grubbing—Heretofore, grubbing has been done by hand labor. It was thought the tractor could be used for pulling the stumps, but after a few successful efforts the gears were badly smashed. Damage to gears amounting to $150 was made on a tree stump which could have been blown up with less than a dollar's worth of dynamite. It is still believed, however, that applying belt power to a windlass-rigged stump puller will prove successful.

Comparison of Cost with Mule Power—The tractor has been used in all traction work formerly done by mules, besides being used for some belt power, for which mules, of course, could not. The tractor regularly hauls in grading two large-sized Buckeye blade graders. These are of a much heavier type than commonly used in the

*Secretary, Board of Supervisors, Caroline County, Va.

Fig. 1. Type of Gasoline Tractor Used by Caroline County, Va.

Fig. 2. Kind of Road Conditions; Tractor Climbing an 8% Grade

FIG. 3. TYPE OF BRIDGE WHICH MUST BE REPLACED WHERE TRACTORS ARE TO BE USED

FIG. 4. NEW REINFORCED-CONCRETE BRIDGE; TWO 26-FT. SPANS; COST $2200

South, and to each six mules are regularly hitched. The graders are also set very much deeper than is possible for any mule team to handle. A cross-section area about 50% greater is cut by the tractor-drawn tool.

METHOD OF USING GRADERS—One grader is hitched with an angle coupling so that it runs in the ditch. The steering gear is locked to hold it in this way. This does away with the need for a steersman, who is needed on mule graders. The blade of this grader is sunk obliquely to the required depth, varying from 6 in. over the blade depth in soft land to a cut of about 12 in. in hard clay or packed gravel. There is practically no rock near the surface in this county. Gravel is used exclusively as surfacing material on improved roads.

The second grader is hitched to a double-length pole, so as to follow the first grader and catch the dirt thrown from the ditch and push it farther toward the crown. Usually this lands the earth dug from the ditches in the right place, and it is seldom necessary to make more than two trips over a section of road to bring the crown to the desired height.

Work has been done in which no less than ten trips of the mule-drawn graders were not equivalent to two trips of the tractor outfit. Another great advantage in using the tractor is that the angle hitch for the ditch grader allows the motive power to travel in the center and hard part of the road. Where the ditches are low and swampy, as much of the valley and low-lying roads in this section are, mules have frequently mired in the mud; or it was impossible to use machine graders at all, so ditches had to be dug by hand at great expense.

COMPARATIVE COSTS—There is some work tractors cannot profitably do, such as light hauling for patching ruts and filling from borrow pits with scrapers. In all other lines, however, this tractor has proved the economy of motor power over mule power.

It is, of course, difficult to arrive at a definite cost price per cubic yard for moving dirt from ditch to crown in road-grading work. But as close a calculation as it has been possible to make indicates that this tractor has moved such earth, in a particularly easy situation for mules, for 2.8c. per cu.yd. By mule power the cost has been 3.2c.

FIG. 5. GRADER AND TRACTOR OUTFIT

FIG. 6. ROAD GRADED WITH TRACTOR AND GRADERS

our county, which means a saving of 9.4c. per cu.yd. These figures cover labor, fuel, lubricating oil, etc., for tractor and [illegible] costs, labor, [illegible], for mules, but not depreciation charges.

[illegible] work has [illegible] for mules, [illegible] with no stumps and moderately soft soil, the tractor cost will show more favorably than a seasonal average, in which [illegible] were called upon to perform all kinds of work.

[illegible] on the [illegible] steep grades [illegible] the [illegible] road administration has permitted, the [illegible] cost will [illegible]. I believe it safe to say that were a seasonal average computed it would show a saving of at least [illegible] per cu.yd. in favor of the tractor.

Because its newness to Southern road officials, and the consequent large amount of "trial motions" they required for other hauling, Mr. Tractor has moved at least 100,000 cu.yd. of road material in Caroline County in the past year, which would indicate a saving of $1000 over the same work done by mules.

The depreciation of the tractor may be figured at $800, while a maintenance account (not fuel or oil, but repairs, etc., to engine itself) of close to $400 has been incurred. However, the largest item of this was for broken gears resulting from [illegible] and this, of course, had better be charged to "experiment" than bona fide maintenance.

It would seem that it has cost $1200 in overhead charges to operate the tractor for a season, but it has effected a saving of approximately $1000 in actual operation costs on grading. In addition to this should be mentioned the belt power supplied, and some hauling economy. On the whole, taking into consideration the fact that the tractor revolutionizes road work wherever it is introduced, and that some time is always needed to adapt the new apparatus to old conditions, the evidence is all in favor of the gasoline tractor's economy.

Irrigation by Pumping Underground Waters in Nevada—The [illegible]

[illegible]

Recent Improvements in the Wire Drag Used by the United States Coast Survey; Its Possible Use as a War Machine

The long wire drag or sweep as developed and used by the United States Coast and Geodetic Survey in hydrographic surveying was quite fully described in Engineering News of Dec. 1, 1910, as most of our readers will probably recall. Since then several improvements have been made in its manipulation, which add much both to its effectiveness and efficiency.

Three wire drag parties are now at work on the coasts of the United States, one near Portland, Me., one in Buzzards Bay and the other on the West coast in Alaska. The importance of this work in effectively and finally verifying charted depths and in discovering uncharted shoals and menaces to navigation is being more fully appreciated, and Congress is even now being urged to pass a special appropriation of $200,000 for work in Alaska, where too frequent shipwrecks on uncharted rocks have shown the inadequacy of the ordinary sounding method on a rocky bottom.

The accompanying illustrations show the present method of handling a wire drag 6000 to 11,000 ft. long. The drag—longer, heavier and stronger than that formerly used—requires larger and more powerful towing boats. The boat shown is a gasoline power tug, about 70 ft. long and 15 ft. beam, especially rigged for a season's work.

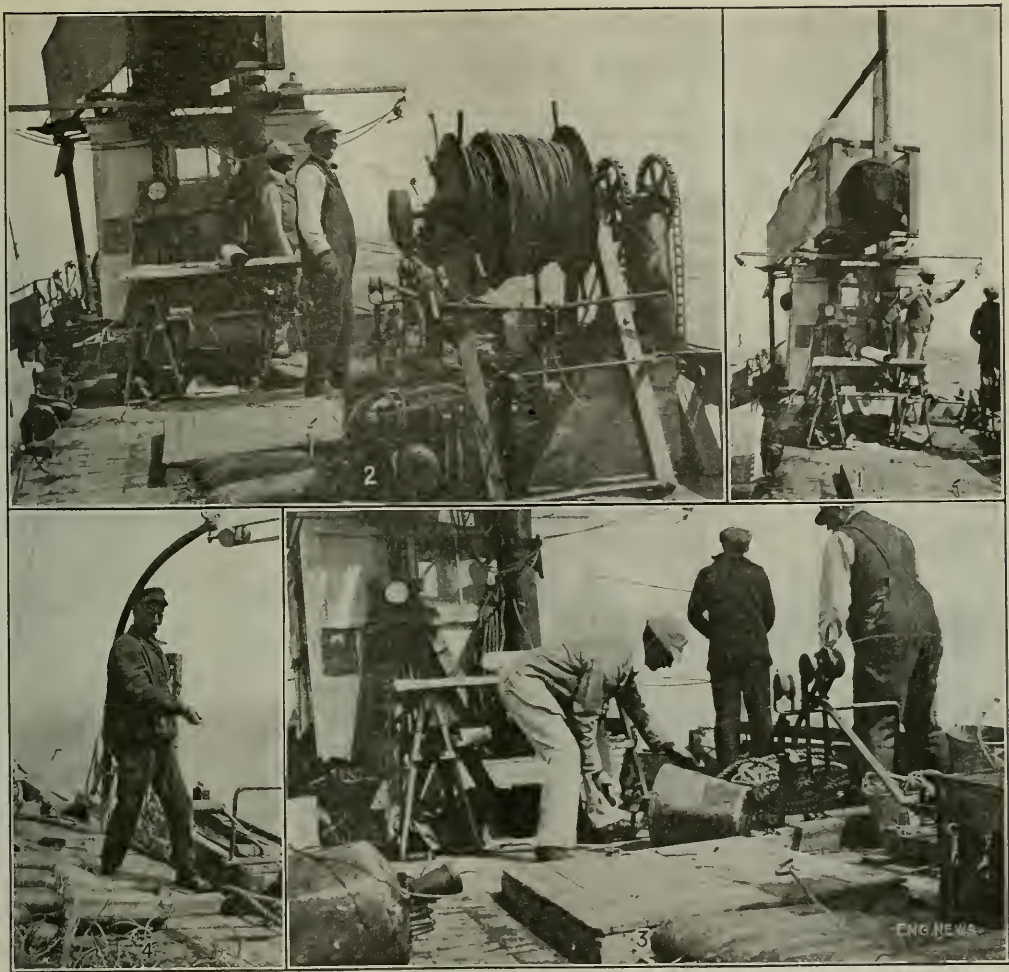
The necessity for frequent communication between the towing boats, which may be a mile or two miles apart, led to the development of the signal system shown in Fig. 1, consisting of three cloth-covered balls, red, blue and white, operated by levers behind the drafting table. The black ball in front is raised and dropped on the hour as a time signal, so that the clocks and watches of both boats may be set to the same time. These four balls are mounted on a binder framework, which can be swung so that its broadside is always toward the other boat.

The ball signal system is supplemented by the U. S. Navy wigwag system of hand flag signals, which permits any kind of a message. The party is now experimenting with wireless telegraphy as a means of drag control. Fig. 1 also shows the drafting table and equipment. The progress of the drag is plotted as the work proceeds.

Fig. 2 shows the apparatus for setting out and taking in the drag. As those familiar with our previous article will recall, the wire drag is merely a horizontal wire suspended, at an adjustable depth, from buoys which are separated [illegible] ft. longitudinally.

The length of the upright wires, or the depth of the horizontal wire, is adjustable to the depth to be cleared, making proper allowance for a tide. Towing the drag from each end, of course, sweeps a strip of bottom and any projection catches and holds the bottom horizontal wire.

The horizontal wire is held down and kept horizontal by [illegible] weights attached to the base uprights. The two ends of the drag are fastened to large towing buoys. Wood floats are attached to the bottom wire at intervals between the buoy uprights. In rolling the drag it is therefore necessary to detach floats, buoys and weights as well as wind up a [illegible]



Wire Drag Work of the United States Coast Survey

Fig. 1. Signal system on leading towboat. Fig. 2 and Fig. 3. Taking in drag with power reel. Fig. 4. Taking off weights, buoys, etc., on bow.

uprights, the wire parts of which remain attached to the bottom wire.

To drive the reel a 2½-hp. gasoline motor is provided. The control of the engine and reel is by levers, handled by the man in the middle of Fig. 3. In Fig. 3 is also shown a pulley device, moved back and forth horizontally by a power-driven cam, to distribute the wire on the reel. Practically the only actual handling of the drag is done by the man on the bow, Fig. 4, who detaches the weights, floats and buoys. He is safeguarded from the incoming wire and attachments by a rope netting.

Obviously the longer the drag the more efficient the work may be done, dependent, of course, on local conditions. The longer drag would not have been possible except by the introduction of methods of mechanical manipulation. With mechanical handling the various safeguards mentioned were essential to the prevention of accidents, especially in reeling in the drag.

It may be interesting to our readers, in view of the great naval battles which are being fought, or are about to be fought in the European War, to know that it is possible to turn the wire drag into a very effective machine for finding out and destroying mines intended to blow up warships. In dragging the coast off New London, Conn., two or three years ago, several practice mines, planted by forces in the mimic war then in progress, were unearthed, and occasionally brought to the surface, by the wire-drag party under N. H. Heck, Assistant, Coast and Geodetic Survey, who is chiefly responsible for the wire drag as it now exists.

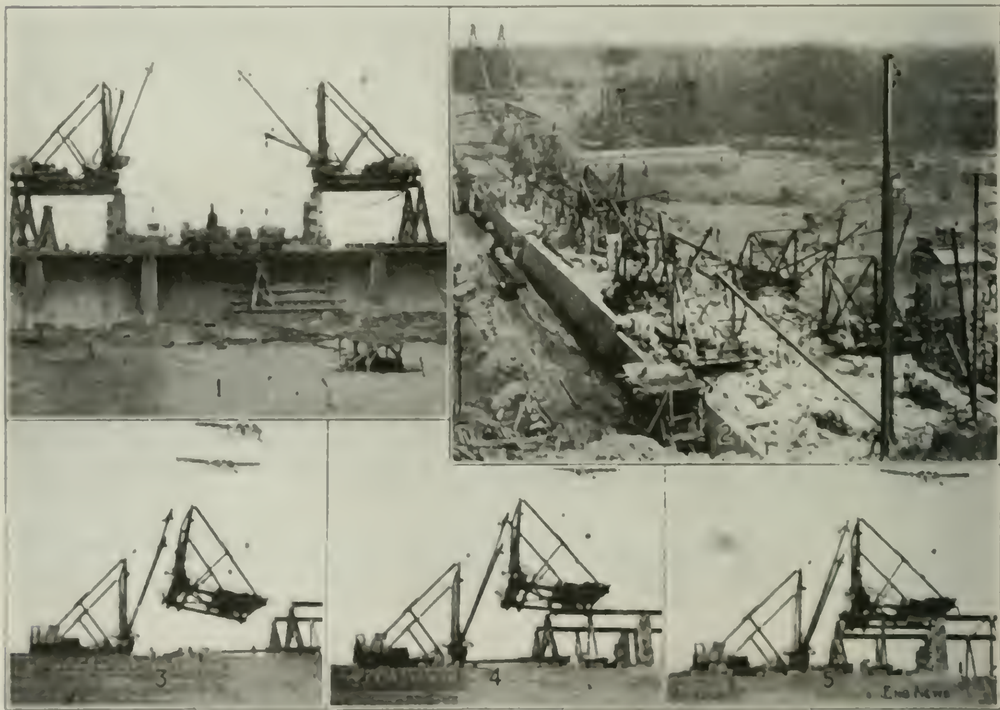
Automobile Exports from the United States in the fiscal year ending June 30, 1914, were valued at $40,136,565, as compared with $39,325,000 for 1913, the latter being the highest on record before this year. Nearly half of the automobile exports were sent to Europe. Imports of automobiles in the year 1914 were only 300 cars valued at about $620,000, as compared with 1624 cars valued at nearly $3,000,000 in 1909.

Field and Office

Shifting Derrick Travelers, Kensico Dam

By Wilson Fitch Smith*

The masonry construction of Kensico Dam, now being built by the City of New York as a part of the Catskill Water Supply System, was described in an article published in ENGINEERING NEWS, May 21, 1914. Briefly, the masonry is being placed by a number of stiff-leg derricks mounted in pairs on travelers. The travelers are carried on elevated tracks supported on masonry piers 25 ft. high (Fig. 5). In the lower portion of the dam, there were two parallel traveler tracks running the length of the dam and the travelers were arranged in pairs, facing each other on each track, so that four travelers or eight derricks served each section of the dam between expansion joints, which are about 80 ft. apart (Fig. 1). The tracks permit the travelers to be readily moved from one section to another as the masonry is completed up to the elevation of the tracks. Above 242, at which the width of the dam is 106 ft., but a single traveler track is used, carrying six travelers permitting three sections to be built simultaneously. The end sections of the dam joining the hillsides are constructed by guy derricks.



FIGS. 1-5. SHIFTING TRAVELERS FROM LOWER TO UPPER LIFT, KENSICO DAM

(Fig. 1. Two travelers working on lower lift. Fig. 2. Looking along Kensico dam showing parallel traveler tracks in foreground and single track in background. Figs. 3-5. Stages in lifting traveler.)

The raising of these travelers to the new elevation tracks as each succeeding lift of the dam is completed is an interesting operation.

The travelers are heavy braced timber frames 30 ft. wide and 50 ft. long, each carrying two stiff-leg derricks with 85-ft. booms operated by double-speed, 75-hp. electric hoists. Fully equipped with counterweights, each traveler weighs about 100 tons. The traveler track consists of two rails 30 ft. apart, each carried on a line of girders made of 24-in. Bethlehem H-beams, 39.5 ft. long. Two spans just cover a section between expansion joints, so that the girders are alternately supported on portions of the expansion joint being built or

*Assistant Engineer, Board of Water Supply, City of New York, Valhalla, N. Y.

of concrete blocks to form piers 25 ft. high in advance of the rest of the joint facing, and on removable framed timber pedestals in the center of each section between the expansion joints; thus obviating entirely the concrete piers used in the lower portion of the dam which were so conspicuous a part of last year's work. This present arrangement is shown in Fig. 1.

After the masonry is completed up to the elevation of the traveler track in several adjoining sections, the expansion-joint-block piers are erected for the new level and the tracks put in place. On the completion of the masonry in the last section allotted to any pair of travelers, one traveler is dismantled by removing the hoist, booms and the counterweights, which are regular concrete blocks used in the expansion-joint facing. This work is done by the cableways and reduces the weight of the traveler to about 48 tons. Then the two cableway hoists are attached to the back end of the traveler by a running bridle and the two derricks of the companion traveler are attached to the front end of the traveler. By concerted action, the traveler is lifted to the elevation of the new tracks (Fig. 3). The cableways are then moved so that the suspended load is drawn over the new tracks (Fig. 4) and guided by the derricks the traveler is carefuly lowered onto the new tracks. This traveler is then reequipped and the other dismantled, and the operation repeated, the upper traveler now helping the lower one to its new position.

The last change, the one illustrated, required less than seven minutes to lift the traveler from rail to rail, and the elapsed time for the complete change from the last masonry placed by these derricks on the lower level to the first placed on the new level was 24 hours, the work being conducted only in daylight hours. As far as possible these shifts are made on Sunday. Fig. 2 is a general view of the dam from the west hill, showing the upstream face. In the foreground four travelers are completing a section to Elev. 242. To the left the single traveler track is erected at Elev. 264.5, and one pair of travelers are being lifted to the new track, as described in this article, while at the farther end of the dam masonry is being placed in a section above Elev. 242.

The dam is being built under the direction of the Board of Water Supply of the City of New York, by H. S. Kerbaugh, Inc.

Forms for Concrete-Encased I-Beam Floor

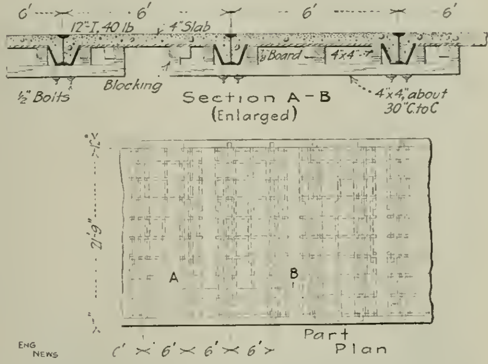
By M. J. Lorente*

In the construction of a private residence of reinforced concrete at Grosse Pointe Farms, Mich., the writer used for one of the floors—a concrete slab with concrete-incased I-beams—a special type of form which was dictated by certain local conditions, but which should prove economical for similar floor designs. A detail of the formwork is given in the accompanying cut.

The main portion of the floor, comprising close to 4000 sq.ft., is supported on 12-in. 40-lb. I-beams, spaced from 6 ft. to 7 ft. 6 in. on centers. The material available on the job for the forms was a large quantity of 4x4-in. timbers ranging in length from 8 to 13 ft., and a considerable amount of ⅞-in. sheathing, all of which had previously been used.

*37 Woodlawn St., Lynn, Mass

The 4x4-in. timbers were in excellent condition, but the sheathing was in pretty bad shape, owing to its poor quality and to the rough handling it had met. So



Details of Formwork for Concrete Floor with I-Beam Stringers

bad was its condition that very little was sound for a greater length than 7 ft. Such being the case, and as the sheathing could be of no further use after the second floor, the writer decided to put up the forms in such a way as to preserve the 4x4-in. timbers as much as possible and to cut only the sheathing.

A set of 4x4-in. timbers had two holes bored near each end, so that they could be secured tightly by two ½-in. bolts to the lower flanges of two adjacent beams, leaving an overhang of about 1 ft. 6 in. at either end. The bolts were bent to fit the flanges of the beams but were not flattened, as is commonly the case. On these cross-timbers were placed other 4x4-in. timbers running parallel with the beams and brought up to the desired height by blocking underneath. Two lines of these longitudinal timbers were placed the proper distance from the beams to allow for the haunches, and another line was placed in or near the middle of the panel. On these timbers was nailed the sheathing, which had to be cut the same length as the clear distance between the top of the haunches. The bevel was formed by sheathing resting on the edge of the beam flanges and the top edge of the longitudinal timbers close to the beams.

The cross timbers were bolted only in alternate panels. In the other panels four lines, instead of three, of longitudinal timbers were used, two close to the beams and two along the ends projecting from the cross-timbers in the adjacent panels. When the exact length could not be made up, the longitudinal timbers were placed side by side so as to avoid cutting. With the timbers close to the beams, cutting was imperative in a few cases, as the timbers had to be in line in order to provide a straight bearing for the boards forming the haunches.

Ribbed Glass to Prevent Drip at Skylights—The elimination of condensation drip from the underside of skylights is claimed to be effected by the use of ribbed or corrugated glass. A special glass for this purpose, with eight ribs or convolutions per inch, has just been put on the market by the Pennsylvania Wire Glass Co., Pennsylvania Building, Philadelphia, Penn., and called "Aqueduct" glass. It is ¼-in. thick, and wired. This ribbing is claimed to have the maximum capillary action.

An Interesting Method for Railway Rechaining

In rechaining the Cleveland Short Line Ry., a unique method was employed. The total distance from Collinwood, where this double-track belt line leaves the L. S. & M. S. Ry., east of Cleveland, to the junction with the same line at Rockport, west of the city, including wye connections with the C. C. C. & St. L., B. & O., and Lake Shore, is 20 miles. Following the standard practice of the Lake Shore, the base line was measured along the center line of the westbound main track.

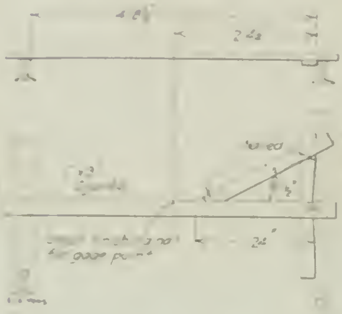


Fig. 1. Track T-Square Used in Rechaining Cleveland Short Line Ry.

The equipment consisted of a 100-ft. steel tape (correct at 70° F., with 10-lb. pull, tape supported at the ends, spring balance at the head end, temperature scale and thermometer on the rear end), a steel brush for cleaning the rail, and two T-squares made of 1x3-in. cypress. These T-squares (Fig. 1) were the special feature of the method of rechaining. The work was carried on intermittently as other work permitted, by the regular field party engaged on construction on the Short Line: assistant engineer, instrumentman, and two chainmen. Each station number was painted on the rail, using white-lead-and-oil, so that the work of making a complete resurvey of the line might be facilitated. No pluses were taken other than marking on the rail the location of mile posts.

In operation, one of the chainmen acted as rear chain, and the other handled the T-square at that end; the instrumentman and assistant engineer worked in similar positions at the head end. At the beginning, one T-square, coinciding with the zero station, was held firmly against the rail and watched to prevent any motion while the measurement was being made. The other T-square, placed in approximate position while the head chain was getting into position to make the measurement, was moved back or ahead a little as the tension was being applied by means of the balance, until the small finishing nail centered in the notch on the 100-ft. point on the tape. Then the head chain reached over and made a line with a slate pencil across the head of the rail along the side of the T-square, held firmly in place by the assistant engineer.

As soon as [illegible] checked, the man handling the rear T-square brought it quickly to the head chain, who started with it to the next station. The assistant engineer, with pot and brush, painted a line down the side of the rail, and painted the station number on the base in figures as large as the width of the base of rail permitted. The station was checked by having the rear chain call out the number of the one he had just left. As an extra precaution against error, everyone in the party carried the station in mind. By carrying the rear T-square ahead and leaving the head one in place for the rear chain to use, any error due to resetting was eliminated.

It was the intention originally to measure with the tape flat on top of the rail on tangents and to use the T-squares on curves only. But on the day the rechaining was begun, considerable difficulty was experienced in getting the tape to lie flat on top of the rail on the first tangent, on account of a high wind. After the first curve had been passed, the use of the T-squares was continued as an experiment on the tangent; so much better progress was made than on the first tangent, that they were used for the balance of the work. Their continual use gave also a uniform unit of measurement, for the reason that the tape was in suspension at all times and under uniform conditions of pull, instead of supported on tangent and suspended on curves.

Rapidity and Cost

No very definite figures as to number of miles to be chained in a day, or cost per mile, can be given, for the reason that the work was done intermittently. On the basis of an 8-hr. day, an average of 1 hr. of which was consumed in going to and from the work, about 4.5 mi. per day was covered. This average may be regarded as a minimum, inasmuch as a considerable quantity of ballast (freshly distributed) had to be dug through to lay bare the base of rail for painting station numbers.

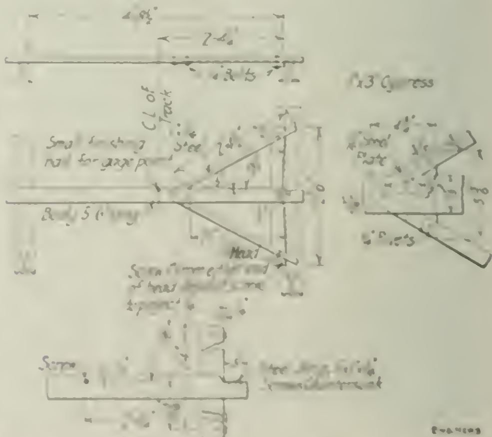

Fig. 2. Improved Track T-Square, Designed for Rechaining a Long Railway Line

The cost of the work averaged about $3.25 per mile, and included only salaries of the four men. On a more extensive job, expenses of the party would be included, but such increase would be somewhat balanced by the employment of lower-salaried men.

ACCURACY

At the west end of the line, an opportunity was had to compare the T-square method with 9 mi. of base-line chaining, which had been done previously with considerable precision, using tripods carrying knife-edges as a part of the equipment. By the tripod method, 1000 ft. was checked back with a permissible variation of 0.01 ft. The difference between the T-square and tripod methods on the 9 mi. was 0.27 ft., or 0.03 ft. per mile.

If a considerable amount of accurate track chaining is required to be done, especially where a fairly high percentage of curvature exists in the alignment, or where the work must be done during the inclement months, the T-square method has advantages apparent to anyone who has chained center line over stone ballast, or through snow and slush. It could be employed to take pluses where objects lying a considerable distance from the track are to be located closely, for instance, in chain surveys of yards and stations. The general custom of taking a plus to a half foot, when the point in the track from which the object bears at right angles is determined by sighting along a tie or by swinging the arms, is of doubtful propriety.

The T-squares used in the rechaining of the Short Line, Fig. 1, were made by a rodman, using material at hand and with as little expenditure of time as necessary, for the reason that the method was considered of doubtful utility and at the most applicable to curves. Since it proved on trial quite economical when degree of accuracy is considered, it might be worth while to make a more substantial tool after the manner of Fig. 2. A good patternmaker would charge about $7 for each.

For information concerning the method of rechaining, we are indebted to John F. Schwed, Office Engineer with the Chief Engineer of the Wheeling & Lake Erie Ry., who was in charge of the rechaining on the Cleveland Short Line. Fig. 2 is a design made by a railroad engineer in anticipation of a large rechaining job.

A Novel Circular Computer

A computing device, based on the principle of the slide-rule, is shown in the accompanying illustration. This computer is claimed to be more accurate than a 20-in. slide-rule, yet possesses an advantage over the regulation slide-rule in being more easily read and operated, and in having a scale for the addition and subtraction of numbers. The gradration is also unique, and much more legible than that of the standard slide-rule scale.

The device consists of a metal frame, to which is fixed a ring plate *B*, a revolving metal disk *A*, about 10 in. in diameter, with two rows of graduations (shown at *C*), the outer a logarithmic scale like that of a slide-rule for operations of multiplication and division, and an inner scale of equal division for addition and subtraction. The figures and divisions of the logarithmic scale are black and of the number scale red. As the main divisions on these disk *A* scales would be hidden at the point where they are read *C*, they are placed outside of the ring plate *B*, where they are always in view. On the fixed ring plate *B* there are exactly similar scales and divisions.

The procedure in using the computer is as follows: With the handle *E* pressed down, revolve the disk *A* until the number to be multiplied (or added to) appears at the index *C*. Lift the knob *E*, raising which clamps the lower plate at the index reading. With the handle still raised turn the arm *D* to the multiplier (or number to be added) on the ring *B* scale. When *D* is set, press down the knob *E*, in which position it clamps the arm *D* on its

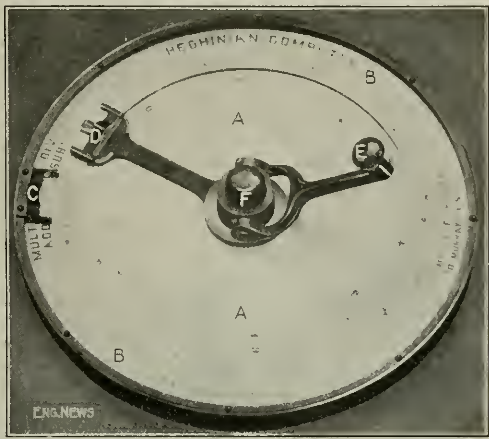

FIG. 1. CALCULATING DEVICE INVENTED BY G. G. HEGHINIAN OF BROOKLYN, N. Y.

reading and unclamps the movement of the lower disk *A*. Now move the arm index *D* by revolving the lower disk *A* to the hair line of index *C*, and we read on the scale at *C* the desired result. If the result is to be divided by any number, instead of moving *D* to the index, move it to this number, and the final result appears at the index at *C*.

In the illustration the index slide *D* is shown set on the logarithmic scale and the index slide *C* on the number scale. These slides cover the scale not in use and thus avoid confusion. Slide *D* is shown equipped with a semi-cylindrical magnifying glass.

The operations of subtraction and division are, of course, the reverse of the process given for multiplication and addition. The result is always read at the index *C*.

Fig. 2 shows some of the details of construction of the computer, which is made throughout of metal, the plates being silver plated. The system of graduation was devised for this computer and makes the close reading of the scale particularly easy. The head *F*, Fig. 1, contains a spiral spring, as shown in the cross-section, Fig. 2,

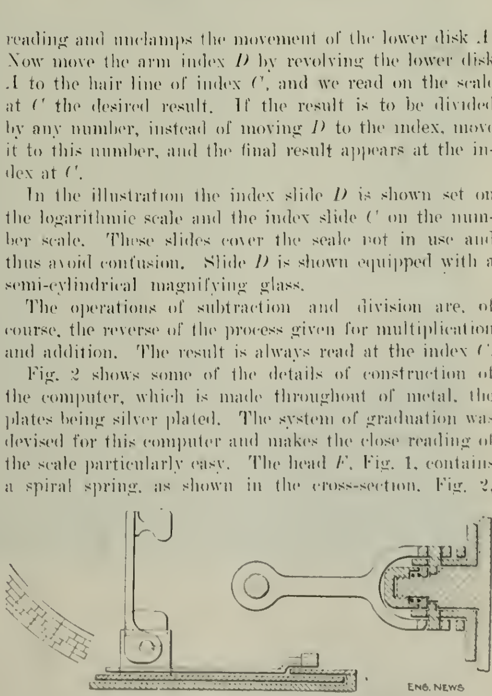

FIG. 2. STRUCTURAL PARTS OF THE HEGHINIAN COMPUTER

which prevents the binding of the plates and takes up any wear on the cam by which the clamping of the plates is accomplished.

The device is called the Heghinian Computer and is

the invention of Irving G. Hag[illegible], a civil engineer, graduate of the Massachusetts Institute of Technology, now is a consulting asphalt expert, at 407 Hamilton Avenue, Brooklyn, N. Y. The maker is F. J. Bernard, 75 Murray St., New York City, and the instrument is made to sell for about $[illegible].

Settlement of a Pile Foundation

A bad case of foundation failure is illustrated by the accompanying views, showing parts of two newly con- [illegible] at least two feet farther down before stopping at hard bottom, and that the soil was not good for more than ¾ ton per sq. ft. Beyond this fact and the known depth to rock the character of the old pile foundation is not known in detail as there was no inspection. The piling plan of the architect (J. Fred Pelham, New York City) shows a double line of staggered piles placed 18 in. c. to c. under all walls; but this was not strictly followed as the presence of large boulders at the front of the site necessitated a certain amount of excavation there and the placing of concrete foundations. This explains why the settlement of the buildings was not more general.

CRACKED WALLS DUE TO FOUNDATION SETTLEMENT

[illegible]

structed apartment houses on [illegible] Place near the Grand Boulevard, the Bronx, New York City. These buildings were founded on wood piles, as the ground is swampy for a depth of 25 to 30 ft. down to rock. Short piles were used, not driven to rock, and under the load of the completed buildings they settled, causing the walls to crack as shown.

Engineers who examined the case for the owners' company found that all the piles they uncovered could be [illegible]

To restore the buildings, [illegible] steel piles were jacked down under the settled portion of the walls. To prevent the possible collapse of the walls, steel cables were tied across inside the buildings at all cracked sections and drawn tight. In the case of one of the buildings, which was in worse condition than the other, timber floats of [illegible] construction were placed in the cellar and in the back yard connected by steel beams which passed the masonry. As this shoring settled under the load of

the settled portion of the building, the cribwork was jacked until firm bearing was secured.

Part of the new steel piling is 12-in., driven with a steam hammer; the remainder of the piles are 9-in., forced down by jacking against the weight of the wall. Sections of the wall were broken out to admit the new piles, which were driven to refusal, blown out with air, reinforcing-rods placed in them, and the tubes filled with concrete. In all, about 80 of these piles were put down along the wall, designed to carry a load of about three tons each.

At the time the buildings were erected, only occasional inspection was given to the piledriving, according to the usual practice of the building bureau. At present, however, the Bronx buildings bureau inspects all piling jobs by keeping an inspector on the job steadily until the piledriving is finished. However, Henry Morehead, Superintendent of the bureau (but not in office at the time these two apartment houses were constructed) says that he considers it an outrage that this should be necessary.

There was no general contractor on this work; contracts for the several elements were let by the owner under the name of the Defender Construction Co.

The Error in Design of Columns for Bending

By J. P. J. Williams*

Columns subjected to bending moment in addition to direct axial compression, are usually designed by an approximate method, which neglects the effect of deflection upon the value of the bending moment. Formulas and diagrams based upon this approximate method by which required areas can be found were given by Mr. Paaswell, in the Engineering News of June 26, 1913, p. 1333. It will now be shown that a relatively simple formula can be used to obtain the error or correction to be applied to the approximate value of the area to obtain the true area required. The percentage of error resulting from the use of the approximate formula is then easily noted.

Let

- A = Total required area of column by the approximate formula (or diagrams);
- A_e = Same area as obtained by more exact formula;
- $A_c = A_e - A$ = error or correction to be applied to A;
- P = Total direct axial stress in pounds;
- M = Maximum bending moment in pound-inches;
- h = Depth of column in direction of bending;
- r = Radius of gyration about an axis perpendicular to the plane of bending;
- s = Allowable unit-stress by column formula;
- l = Unsupported length of column in inches;
- E = Coefficient of elasticity in pounds per square inch;
- k = Constant depending upon end conditions (= 32 for fixed ends; 10 for pin ends; 24 for one fixed, one pin end.)

Also, let $\dfrac{M\left(\frac{h}{2}\right)}{r^2}$ be called P_b, and $\dfrac{P\left(\frac{l}{r}\right)^2}{k\,EA}$ be called K.

*Assistant Professor of Structural Engineering, University of Minnesota, Minneapolis, Minn.

The approximate formula generally used can then be given in the following form:

$$A = \frac{P}{s} + \frac{Mh}{2r^2s} = \frac{P + P_b}{s}$$

As developed in standard textbooks on the subject, the more exact formula for total stress s is:

$$s = \frac{P}{A_e} + \frac{\frac{1}{2}Mh}{I - Pl^2 \div kE}$$

By substituting A_er^2 for I, and assuming for practical purposes that $\frac{A_e}{A} = 1$ in the second term of the second denominator, the value of A_e is found to be:

$$A_e = \frac{P + \dfrac{M\left(\frac{h}{2}\right)}{r^2 - \dfrac{Pl^2}{kEA}}}{s} = \frac{P + \dfrac{M\left(\frac{h}{2}\right)}{r^2\left(1 - \dfrac{Pl^2}{kEAr^2}\right)}}{s}$$

$$= \frac{P + \dfrac{P_b}{1-K}}{s}$$

Therefore

$$A_c = A_e - A = \frac{\dfrac{P_b}{1-K} - P_b}{s} = \left(\frac{K}{1-K}\right)\frac{P_b}{s}$$

This A_c is the error on the side of danger when columns are designed by the approximate formula

$$A = \frac{P}{s} + \frac{Mh}{2r^2s}.$$

In most cases the error is only a very small percentage of area A. But the error varies directly with K and with P_b, and therefore increases with increased slenderness $\left(\frac{l}{r}\right)$ and increased bending moment.

Procedure—In designing columns with the use of the foregoing, proceed as follows: Assume depth h, obtain r by approximate ratio (see Engineering News, May 23, 1912, p. 991), compute $P_b = \frac{Mh}{2r^2}$, and then $A = \frac{P + P_b}{s}$. Next compute $K = \frac{P}{kEA}\left(\frac{l}{r}\right)^2$, and finally A_c, and determine the percentage of error.

Stump Pulling and Grubbing Machine

In the clearing and development of large tracts of land, the grubbing and removal of stumps quickly and economically is a problem, for modern conditions do not favor the old practice of leaving the stumps to rot or to be burned and pulled out piecemeal as the farmer can find time for such work.

There is a large field for machines which can do this work effectively at low cost, and the accompanying cut shows a machine which has been designed for this class of work. It is self-propelling, while light enough to travel over soft ground. It is designed to grub out the smaller stumps as well as to pull the large stumps, thus doing the entire work of clearing rapidly and at reasonable cost.

The machine consists of two parts, the tractor (with

Stump-Pulling and Grubbing Machine for Clearing Land

hoisting engine, and the hoisting tripod. When at work, the latter rests on shoes on the ground and is entirely free from the tractor. For moving from stump to stump, the tripod is tilted and raised so as to be carried clear of the ground by the tractor. The tractor has a 20-hp. horizontal engine and a vertical boiler. The engine is geared through a [illegible] clutch to the traction mechanism driving the rear wheels. For hoisting, the power is applied to two drums mounted at the front end of the frame, geared to give a powerful pull. For raising and lowering the tripod there is an auxiliary drum mounted on the gallows frame at the rear of the machine.

[illegible]

The wire rope from one of the drums leads to a pair of blocks suspended from the top of the tripod, and the [illegible] power can be increased by varying the number and arrangement of the sheaves. It is stated that a pull of about 45 tons, which is easily within the capacity of the machine using a pair of 3-sheave blocks, is ample for pulling stumps up to 7 ft. diameter. After the stump is pulled, it is the work of a few moments to tilt the tripod, move to the next stump, and drop the tripod into position again. It is only necessary to use the tripod for stumps of the largest size, which are usually a small percentage of the total. All the lighter growth and smaller stumps are pulled by the ropes running forward directly from the drums.

[illegible]

The tripod also affords a means of piling the stumps. For this operation, the rope is run through a block at the top of the tripod and the tripod guyed to a stump in the rear. The stumps can then be [illegible] at a higher speed on the drums being provided for this purpose, and they are readily dragged up into piles of considerable height.

This machine is being introduced by the Pioneer Land Clearing Machine Co., 1220 First National Bank Bldg., Chicago. On work in Ogemaw County, Michigan, the machine has pulled 200 stumps per day, the stumps ranging from 8 to 36-in. diameter.

A Model Town, known as Morgan Park, is being built within the city limits of Duluth by the Minnesota Steel Co., in connection with its new steel works at that city. [illegible]

Traveling Car-Tipple on the Sag Canal

In the construction of the Chicago Drainage Canal a most important feature was the use of various forms of machinery for the removal of excavated material. One type of machine consisted of a traveling tipple or car dump, the cars on which received material from the steam shovel and dumped it to form a spoil bank at a suitable distance. Machines of this type have been used on other canal work, and are now being employed on part of the Sag Canal, which is an auxiliary channel extending from the Calumet River to the "Sag," a point on the Chicago main drainage canal. This Sag Canal was described in our issue of Jan. 23, 1913.

The new car tipple noted above is in use on contract section No. 9 of the canal work, 5500 ft. long. The cross-section here is 180 and 36 ft. top and bottom width, 37 ft. deep, with side slopes of 2 on 1, and 100 ft. width of berm. The rock lies at an average elevation of 10 to 12 ft. above the grade line of the bottom of the canal. The plan is to remove all the material above the rock in one cut, the steam shovel being placed in such position that it can take out the full section of the canal. It loads the material into two cars running on the incline of the tipple; each car holds two dipper loads, and while one car is being loaded the other is being dumped.

The steam shovel is of the stripping type (ENGINEERING NEWS, Apr. 2, 1914), having a 75-ft. boom and 3½-yd. bucket; its upper part revolves on a main frame supported by four four-wheel trucks on two parallel tracks. Fig. 1 is a view of the entire plant, and shows the dipper about to deposit its contents in one of the two cars of the double-track incline or tipple.

The construction of the tipple is shown in Fig. 2. It consists mainly of two triangular trusses spaced 16 ft. c. to c., with the horizontal part of the bottom chords supported on two cross-frames. Each frame is carried by seven pairs of wheels on a standard-gage track, these tracks being 75 ft. apart, c. to c., laid parallel to the line of the cut, and the inner track being near the edge of the slope. The outer part of the structure forms a cantilever 80 ft. long, with its end about 60 ft. above the ground, and beyond its end projects the car-dumping platform. The boiler and machinery mounted on the deck serve to counterbalance the cantilever arm.

On this structure are laid two tracks, upon each of which runs a 7-yd. four-wheel car operated by a cable. To extend these tracks into the cut, so as to put the cars within the reach of the steam shovel, there is an apron 30 ft. long, hinged to the main frame and having at its lower end a 12x12-in. oak bolster which rests on the slope. Eyebars at the outer corners of the apron carry sheaves for tackle, led over masts on the main frame. Once a day the machine has to be moved forward about 30 ft., and the method of raising the apron during this movement is one of the special features of the new machine. The ends of the hoisting cables passing over the masts are attached to one of the dump cars. Then by hauling the car up the incline the apron is raised and held until the machine has been moved forward to its new position. As the steam shovel advances, the machine is moved forward by means of a hauling tackle and blocks, one block being hitched to an anchor or deadman.

FIG. 1. TRAVELING CANTILEVER CAR TIPPLE ON THE SAG CANAL, CHICAGO, DELIVERING MATERIAL FROM STEAM SHOVEL TO FORM THE SPOIL BANK

At the upper end of the cantilever each track has a pivoted dumping platform 16 ft. long, the outer end of which carries the 5-ft. sheave for the car cable. The ends of the track rails are curved upward so as to embrace half the diameter of the front wheels of the car, thus holding the car firmly upon the track. To the tail end of the platform is attached a cable leading to a pendulum counterweight suspended in the truss.

As the loaded car runs upon the tilting platform, stirrups at the rear engage with dogs on the platform so as to hold the car in place. When it runs against the curved stop rails it automatically trips a latch which holds the platform, and the continued pull of the hoisting cable (together with the weight of the car) causes the platform to tilt on its horizontal shaft to the position shown by the dotted lines. The counterweight at the same time is raised to horizontal position, as shown, its effect increasing as the tipple is being revolved. The hoisting cable being slackened, the counterweight overcomes the weight of the empty car, and pulls the platform to its normal position. Fig. 3 shows the platform in the dumping position.

The equipment includes a 100-hp. horizontal boiler and a hoisting engine with cylinders 10½x12 in. The drums

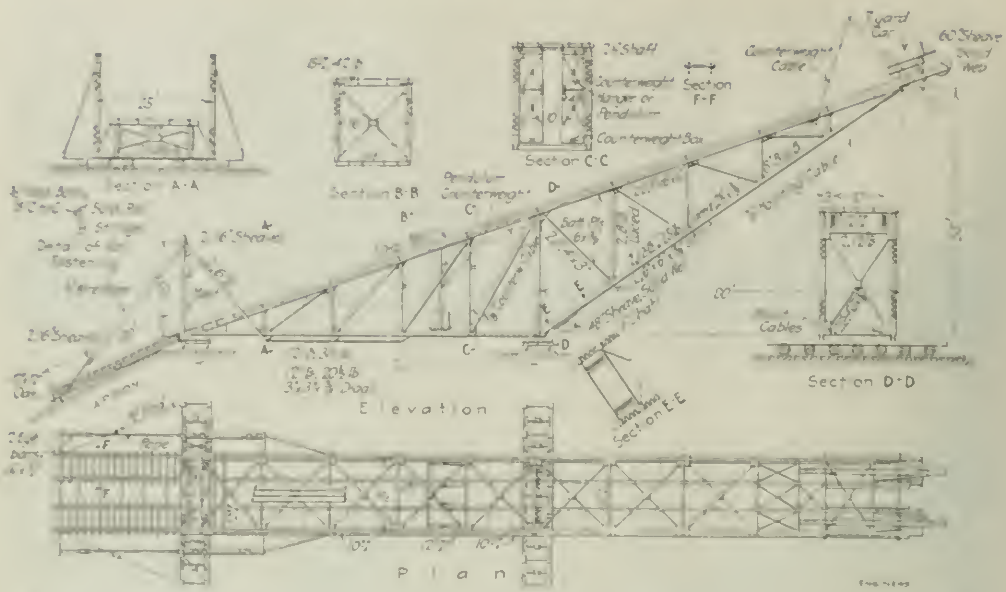

FIG. 2. DETAILS OF TRAVELING CANTILEVER DUMP OR TIPPLE, SHOWING THE DUMPING PLATFORM AND THE APRON EXTENDING INTO THE CANAL EXCAVATION

are 48 in. in diameter, placed tandem, and have band frictions and brakes. The friction bands are operated by steam rams. The speed of the hoisting cables is about 300 ft. per min. The engine is mounted on a separate car on the track nearest the slope of the cut. This is done in order to put the operator in a position where he has a full view of the cars throughout their entire travel.

The machine is used by the Byrne Bros. Dredging & Engineering Co., of Chicago, which has the contract for this section of the Sag Canal. It was designed by the Page Engineering Co., of Chicago. It is very similar to the machine used by Gahan & Byrne, contractors, on the main drainage canal (as already noted). The loads hoisted are greater, however, so that the present machine is somewhat heavier. It also has the new arrangement for raising the apron, as described above. It is too early to give any records of monthly output or daily average, as a good part of the work so far has been in starting the cut and getting the steam shovel down into the pit. However, the contractors state that 2000 yd. have been moved in a single shift, and that this is not its greatest capacity.

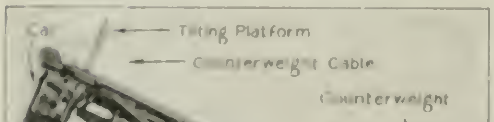

FIG. 3. CAR BEING DUMPED AT HEAD OF CANTILEVER TIPPLE

Calculating Earthwork Cross-Sections

WELLS' METHOD—Various opinions have come to us regarding the method of calculating earthwork cross-sections given by L. W. Wells on p. 1203, of the issue of June 11. F. E. Foss, professor in charge of the department of civil engineering, Cooper Union, New York City, considers Mr. Wells' method "much more cumbersome than that based upon subdividing the area into triangles, which consists in multiplying the cut or fill by the difference in the distances out from the center." Another correspondent states that practically the same method is given in Nagle's "Field Manual for Railroad Engineers" pp. 189-190 (1897 ed.). Others have called our attention to the similarity of Mr. Wells' method to that given in our own columns in 1902, as noted in our issue of July 9, p. 89.

C. E. Gibler, of Greeley, Colo., writes that he has used the method given by Mr. Wells for years and has calculated hundreds of miles of cross-sections for railroads, highways and ditches by it. He says:

I am acquainted with numerous other engineers who also favor and use it. On the other hand, I am acquainted with many who are strongly prejudiced against its use, principally for the reason that its proof is not obvious, and they have long used the easily proven trapezoidal method.

The method advocated by Mr. Wells, which the writer has always designated as the "triangular method," is quick, and is less tiresome, and, by reason of occasioning no mental subtraction and addition, less prone to error, than the trapezoidal method.

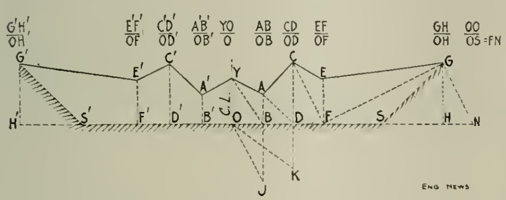
There are an infinite number of ways in which the truth of the method may be proved, but many would lead into a maze of calculations from which it would be nearly impossible to extract the relationship between the notes and the area.

The writer therefore believes that a study of the proof given herewith will convince many, not only of the truth of the method, but also of its simplicity; and prove that this triangular method is really a very close relation to the beloved trapezoidal method.

The accompanying figure represents a section in excavation in irregular ground, which for the sake of this analysis is made symmetrical about the center line. The left half is divided into trapezoids, and the right half for proof by the triangular method. Double areas are considered for the sake of convenience exactly as they are in the trapezoidal method.

Above the figure is a set of notes indicated by letters instead of numerals.

The manipulation of the notes has been fully explained by Mr. Wells and so will only be reviewed here in analysis.



ADDITIVE AREAS

Notes		Figures
YO × OB =	The double area of triangle	YOB
AB × OD =	" " " "	ABY and ABD
CD × OF =	" " " "	ACD, FCD, and OBJ in which BJ = CD
EF × OH =	" " " "	CEF, GEF, and ODK, in which DK = EF
GH × OS = GH × FN =	" " " "	GFN wihch equals GFS plus GSN

SUBTRACTIVE AREAS

OH × Zero = Zero		
GH × OF = GH × SN =	The double area of triangle	GSN
EF × OD = DK × OD =	" " " "	ODK
CD × OB = BJ × OB =	" " " "	OBJ
AB × Zero = Zero		

We have therefore deducted each of the external triangles and have remaining the area of the half section considered, (neglecting the operation of dividing by two) Q. E. D.

A brief examination of the left half of the figure discloses the reason for the external triangles in the analysis. Considering C'D' we observe that for double areas in the trapezoidal method it is multiplied by the distance to the intermediate on either side of B'D' and D'F', or all told, B'F', whereas in the triangular method CD is multiplied by OF, which is in excess of the amount B'F' by the amount OB, and we have, therefore, to exclude a triangle whose base is OB and whose altitude is the equivalent of CD, or the triangle OBJ, etc.

LOVELACE'S METHOD—O. G. Bunsen, of 1882 San Berbard St., Austin, Tex., writes that for the last 20 years he has used a method of calculating the end areas for earthwork formulas which is practically identical, but more concise, than that given by E. S. M. Lovelace in ENGINEERING NEWS, May 28, p. 1200; and he inherited it from engineers who came before. The difference is that the horizontal axis OX, or reference line, instead of being the H.I., as in Mr. Lovelace's method, is the grade level. The field notes are recorded to show the actual cuts and fills.

Referring to Mr. Lovelace's demonstration of notes taken from Sta. 41, and Fig. 3, p. 1201, the notes would read:

Sta.	Elev.	Grade		Left		C		Right		
41	97.40	91.50	$\frac{0}{10}$	$\frac{+1.7}{12.5}$	$\frac{+3.8}{8.0}$	$\frac{+5.9}{\text{sta.}41}$	$\frac{+7.2}{6.0}$	$\frac{+6.4}{13.0}$	$\frac{+6.9}{20.4}$	$\frac{0}{1}$

By Mr. Bunsen's rule; $2A$=algebraic sum of the products obtained by multiplying each distance out by the difference of the adjacent heights either side of the distance out, always taking the height between the center and the distance out as the minuend.

$$2A = 10(1.7 - 0) + 12.5(3.8 - 0) + 8.0(5.9 - 1.7) + 6.0(5.9 - 6.4) + 13.0(7.2 - 6.9) + 20.4(6.4 - 0) + 10(6.9 - 0) = 298.56.$$

$$A = 149.28.$$

The value of this rule, Mr. Bunsen says, consists in that it is automatic, following a fixed routine, thereby avoiding the error of skipping some of the data. The rule is general and can be applied to any kind of a cross-section.

This method is similar to the one given by C. F. Koppisch in the issue of June 11, p. 1303, which is criticised by Mr. Lovelace as follows:

My method given in "Engineering News" of May 28, p. 1200, is a general one, independent of any particular method of keeping field notes. In the notes as given on p. 1201 the numerators are the actual rod readings and the denominators the actual distances out from center. While it may be a convenience in some cases to have notes recorded as showing the actual cuts and fills, so far as arriving at the area of the section is concerned, nothing at all is gained and time is lost in subtracting the rod readings from the grade-rod reading in the field and so recording them. The method under discussion is principally of use where the sections have numerous intermediate readings, and then any device that will save time either in the field or office is of value.

NOTES

A Good Detail for Measuring Boxes—Measuring concrete materials accurately is essential to good work. On one section of the Passaic Valley Sewer, the contractors, Frazer & Burchenal, are using a small rotary batch mixer and measuring sand and cement in home-made boxes which are built as shown in the accompanying sketch. These boxes are made throughout of 1-in. material; the end pieces afford not only a good tie, but a very good handle by which the boxes can be lifted.

Immediate South American Needs

When the serious nature of the present European war was realized, the Bureau of Foreign and Domestic Commerce of the United States Department of Commerce directed the various consuls in South America to report on the classes of goods most required in their localities now that European imports have ceased. These reports, which have just been circulated, have interest to manufacturers of engineering materials, and indirectly to those engineers who may contemplate entering the South American field, for if American material is to go south, American men will undoubtedly follow.

While a large part of the goods now required are outside of the engineering field the demand for cement and steel is widespread even thus early, which would indicate that construction work is either in progress or in prospect and that contractors supplies are going to be a need of the immediate future. The various cities and their specific engineering needs are as follows: Para—cement, manufactured iron; Rio de Janeiro—cement, steel wire; Montevideo—cement; Lima—cement, steel rails, tools, machinery, explosives; Bogota—machinery, railroad supplies, engines, cars, rails, bridges.

An Engineering Study of Smoke from Pittsburgh Boiler Plants

From time to time we have noted the smoke-prevention investigations in Pittsburgh regarding which, up to the present, only general information has been available. There now comes to hand a bulletin of the Mellon Institute of Industrial Research of the University of Pittsburgh, giving data on the operating conditions and smoke production of 147 stationary boiler plants (191 stacks) in Pittsburgh variously equipped with and without machine stokers. The general results of this survey are of wide interest, as comparing the relative smoke production of various systems of firing fuel under commercial operating conditions which are likely to be seen anywhere. Briefly reviewed, these data show that the 51 common hand-fired plant stacks, while under observation, produced no smoke 30 minutes out of an hour: 11 stacks from Dutch-oven furnaces were smokeless 34.5 minutes, the 36 chain-grate stoker plant stacks were smokeless 38 minutes, the 60 front-feed stokers 23 minutes, the 21 side-feed stokers 11 minutes, and the 12 under-feed stokers 13 minutes. The minutes per hour of producing 60% black smoke, or denser, for all these plants were: hand fired, 12; Dutch-oven, 5.2; chain grate, 2; front feed, 15; side feed, 2; and underfeed, 1. The average densities of smoke, compared with black, were: hand fired, 23%; Dutch oven, 13.6%; chain grate, 11%; front feed, 27%; side feed, 8%; and underfeed, 7%. The interesting point is the failure of front-feed stoker plants to work as well as the hand-fired boilers.

A New Danger for Bridges

By liberal use of scissors and paste on a recent issue of the Service Bulletin of the Iowa Highway Commission, we are enabled to present the following gem:

Treacherous danger lurks in the old style bowstring type of iron bridge. There are thousands of them on main traveled roads in Iowa.

You can see the danger in the rotten wooden bridge. The signs of decay are unmistakable. You cannot see the danger in the old crystalized iron. Your first intimation of danger in the age weakened structure comes with the sudden snapping of rods and beams and a crashing of wooden floor timbers. Between the two, the old bowstring is more treacherously dangerous than the rotten wood.

There was little thought of danger on the Rutland bridge when a steam traction threshing outfit started across. Yet half a minute or so later the whole outfit lay at the bottom of the Des Moines River.

There was no thought of danger when a similar outfit steered upon the Thornton bridge, yet only a projecting shelter formed by a self-feeder on the separator which striking the engine as the bridge went down kept a small space between the separator and the engine and saved the lives of the engineer and the steersman (sic).

Every man who has crossed one has noticed the trembling of the structure and the rattle of the rods and members of the bridge. The metal in them has every inducement to crystalize.

We restrict the above quotations to the essentials. Were it not for this we would go on and relate, still quoting, how thousands of these bridges, freshly painted and good looking, are "waiting, veritable death traps set with the fickly hair trigger strength of crystalized metal."

In the past bridges have broken down because they were overloaded; that is to say, either loads were run upon them which were greater than they were designed for, or being perhaps poorly designed or built they were unable to carry the loads which the design supposed them good for. But now we learn that there is a third and more lurking danger—one that has a "fickly hair trigger strength."

In view of the great importance of this to bridge engineers and the vast public which occasionally uses bridges, we call upon the editors and backers of the Service Bulletin of the Iowa Highway Commission to present all obtainable and necessary facts on the new danger and to thus demonstrate it to the world in order that all may take proper steps for protection. Since the old superstitions about the so-called crystallization of structural metal have long ago been killed off, something new must have been discovered in Iowa. We call for the facts.

It may be, of course, that the real danger to bridges is not the "fickly hair trigger strength" above referred to, but the Iowa Highway Commission itself. If that be the case, the nation at large is not in as great danger as Iowa; at the same time the process of cure is simpler.

Why Not Preserve the Natural-Cement Industry?

A few years hence the engineer who happens to be engaged on a piece of work where he prefers, for certain reasons, to use natural cement, or, as it is perhaps most commonly termed, Rosendale cement, will find, we fear, that he cannot obtain it in the market. It seems to us that this would be a serious misfortune and that the engineers of the country will do well to consider whether they ought not to make a larger use of natural cement. For it rests absolutely with engineers whether this industry shall survive or whether it shall become one of the lost arts.

Most engineers of mature years know that up to about 15 years ago most of the cement used in the United States was natural cement and natural cement only. In 1890, for example, over 7,000,000 bbl. of natural cement were produced in the United States. In the same year only 335,000 bbl. of Portland cement were made in the United States and 1,940,000 bbl. were imported. Not till 1896 did the annual production of portland cement in the United States exceed a million barrels; and in that year nearly 8,000,000 bbl. of natural cement were produced. In 1900 the production of portland cement exceeded the production of natural cement for the first time. Since then the production of portland cement has increased by leaps and bounds, amounting to 92,-097,000 bbl. last year. The natural-cement industry has declined meantime, falling below 1,000,000 bbl. for the first time in 1911.

It may be said that the reason for the decline of the natural-cement industry is a commercial one. Portland cement made by modern processes in huge plants is produced at so low a figure that the natural cement, produced on a comparatively small scale and by old-fashioned methods, could barely compete with it even if the two materials stood on an equal footing in the market. Of course, they do not stand on an equal footing. Portland cement is recognized as on the whole a superior material to natural cement, so the purchaser, or the builder, or the engineer says, "since the difference in cost is so little, let us specify the best material."

If this were indeed the whole story, then we might look upon the disappearance of the natural cement industry with equanimity. But is this the case? Some of the older engineers, thoroughly experienced in the use of natural cement, can testify to the excellence of this material when properly handled. It has moreover some characteristics which portland cement does not possess. It is for one thing slow setting, and slow setting by nature and not by reason of artificial additions to the mixture. In the second place it lends itself readily to a number of uses to which portland cement is not by any means so well adapted. It works under the trowel like lime mortar, with a smooth, buttery consistency that conduces to good workmanship. Portland-cement mortar, on the other hand, has little consistency and it is very difficult to give it exactly the right texture to handle well with the trowel. A great deal of work has to be finished either too dry or too wet for the best results.

Again, natural cement has a record of experience back of it that is possessed by very few works in portland cement. It is true a great deal of the old works in natural cement were laid with an admixture of lime mortar. There are, however, plenty of old structures standing in the State of New York and elsewhere, which were built in the days when natural cement was practically the only reliance of the engineer and whose condition today gives eloquent testimony to the excellence of that material. In contrast with this must be placed some of the experiences in recent years in connection with the disintegration of certain structures built with portland cement. The cause of this disintegration is still a matter of controversy among cement experts.

Of course, it is believed that the causes of this disintegration will in time be discovered and removed; and we are by no means suggesting that portland cement does not fully deserve its present high reputation. It does seem worth while, however, for engineers not to lose sight of the merits and excellence of natural cement for works to which it is adapted. As we pointed out in the beginning, the great trouble is that if they continue to neglect the use of natural cement they will soon be in a position where they cannot secure this valuable material no matter how much they may happen to want it.

A Dangerous Attack upon Standard Time

Some of the older readers of Engineering News may remember the confusion that existed throughout the United States prior to 1883 with reference to time. Since the true astronomical time, measured by the movement of the sun, differs at every point on the earth's surface, every city and town, if it used the astronomical time for its own location, would have a time different from every other city not on the same meridian.

Up to the late '70's, nearly all the railways of the United States were comparatively small isolated lines. The general practice was for a railway to take the astronomical time of the city where its principal offices were located and use that time for all points along its line. Small towns and cities usually used the same time as the railway, but larger cities often used their own time for local purposes and it was common to hear "city time" and "railway time" referred to. Connecting railways at a junction point often used different times, so that in the same city three or more different times might be in use.

To the general public, this meant a vast amount of confusion and uncertainty. To the railways it meant, in addition, a very serious danger. There was always risk that some employee's watch would be by mistake set to some city time instead of railway time or that there would be confusion between the relative times of connecting railways.

When railway consolidation and expansion and the construction of the great transcontinental lines began, the absolute necessity for radical reform in the matter of time became evident. It was this, in fact, which first brought the railway companies together for general conference in an organization which was the predecessor of the present American Railway Association, and was for years known as the General Time Convention.

It is worth noting that the most influential figure in bringing about the adoption of the present system of standard time was an eminent civil engineer, Sir Sandford Fleming, of the Canadian Pacific Ry. Another who

deserves special credit for this great reform was also a well known civil engineer. Mr. W. F. Allen, who still continues his responsible work as General Secretary of the American Railway Association. The present system of standard time was the result of more than two years of thorough and careful study. It was adopted on Nov. 18, 1883, and for more than 30 years has continued in use. No one who realizes the chaos and confusion and danger that existed in connection with matters of time distribution previous to 1883 would dream of countenancing any movement that might cause a return to those conditions even in part.

On May 1, 1914, an ordinance became effective in the city of Cleveland which makes Eastern time, instead of Central time, the legal standard in that city. A traveler to Cleveland who sets his watch back an hour when he passes Buffalo, finds when he reaches Cleveland that he must set his watch an hour forward again to Eastern time. If this were all, it would be a local matter affecting Cleveland only; and so long as its citizens choose to put up with the annoyance and difficulties due to having local time one hour different from the time of the railways entering the city, it would be of little importance elsewhere. Cleveland, however, is bringing strong pressure to bear upon the railways entering the city to induce them also to change to Eastern time. Other Ohio cities seem to have a vague idea that there is something progressive involved in this change and are agitating for a similar action, and it is even proposed that the entire State of Ohio shall adopt Eastern time as its standard.

If this movement should be forced through—and there is danger that it may be, in view of the control over the railway companies now held by the State Railway Commissions—it will necessitate a complete revision of the points of change from Eastern to Central time all the way from the Canadian border to the Gulf of Mexico.

The executive committee of the American Railway Association has seen and realized the danger. In a report presented at the last meeting of the Association, the committee says:

> If the system of uniform standard time is to be changed in a way which may threaten its impairment or destruction, the final action taken should be at least as deliberate and unanimous as at the time of its adoption. Certainly individual railways or communities ought not to pursue a course which may be detrimental to other railways or to the public interest, without competent and careful consideration being given to the effect upon those interests.

It is difficult to see any justification whatever for Cleveland's action in changing its local time from Central to Eastern. If the motive in making the change was to give the city its true astronomical time instead of the standard railway time, then nothing has been gained. Cleveland is situated about midway between the meridians of 75° and 90° west of Greenwich, on which Eastern time and Central time, respectively, are correct. Thus, while the Central time is half an hour behind Cleveland's true astronomical time, Eastern time, which it has now adopted, is half an hour ahead.

We understand the argument brought forward in Cleveland is that in using Central time the day's work begins half an hour later than it should, and continues half an hour later in the evening. By the change to Eastern time, however, men now go to work half an hour earlier than Cleveland's true astronomical time, and quit half an hour earlier at night. If what the City wanted was to run on true astronomical time, then it should have adopted, not standard railway Eastern time, but a local time of its own, which, if made exactly half an hour different from the Central time, would have caused comparatively little confusion. If, however, the city wished to accomplish the thing it has now effected; to wit, to set the time of beginning and quitting work an hour ahead, it was not necessary to interfere with standard time at all, but simply order that factories and other places of work which now begin at seven o'clock, Eastern time, should start at six o'clock, Central time. The results obtained would have been absolutely identical with those that the present plan secures, and there would have been no upsetting of the system of railway standard time. It may be claimed that the unions and others would object to men being compelled to start work at six o'clock in the morning instead of seven, yet this is exactly what they are compelled to do by the change to Eastern time instead of Central time. Calling a horse by a different name does not change its color.

We hope the railway companies of Ohio, and the public authorities over them, will appreciate the dangers to the present satisfactory system of standard time which will result if railway-time standards in Ohio are changed to correspond to the whims of different localities. The matter of standard time is too serious and important, and is too far reaching in its effect to be a proper subject for municipal interference.

Letters to the Editor

Tidal Currents in the Cape Cod Canal

Sir—In your issue of Aug. 6, 1914, p. 321, you gave an interesting account of the opening of the Cape Cod Canal, and made reference to the operative problems that will be met in working a 100-ft. canal in a tidal current.

As you state in your article, the canal prism is not yet completed; for many reasons it was desired to commence operations before completion.

The canal is of special interest in connection with the study of hydraulics, inasmuch as it is perhaps the only waterway of comparatively uniform cross-section connecting open bodies of tide water with considerable difference in tidal elevations. It will provide a means of determining questions of flow of water through channels of large cross-section, which are hardly covered by the existing hydraulic formulas, necessarily based on canals of much smaller dimensions.

The tides in the two bays are substantially half tide apart; that is to say, when it is mean sea level on one end it will be high or low tide on the other, and the

maximum difference in both directions on mean tides is about 5 ft.

Until the canal is completed no final or accurate determinations of the velocity of the current are obtainable. First measurements made through that portion of the canal where the depth is the minimum and where consequently the total current for the moment is at the maximum, show a current at the top of the tide for the average cross-section of the canal of 2.47 knots, and with a current very much less than this in those portions of the canal where it is full depth, or where the width is in excess of the 100 ft. This, of course, disposes of statements which have found their way in the press of currents greatly in excess of the above.

When the canal is completed it is my intention to make a complete analysis of tidal conditions and currents and publish the same in a paper.

From July 30 to Aug. 16, although limitations to a draft of 15 or 16 ft. were placed upon the boats that could be passed through the canal, 188 boats used the canal exclusive of the contractors' plant, of which 166 went through under their own power and 22 in tow.

There is no erosion, the water in the canal being perfectly clear.

Wm. Barclay Parsons,
Chief Engineer, Cape Cod Canal.

New York City, Aug. 19, 1914.

Another Proportional-Flow Weir; Sutro Weir

Sir—The article by Prof. E. W. Rettger, "A Proportional Flow Weir," Engineering News, June 25, 1914, is of particular interest to the writer, and prompts him to call attention to a type of weir known as the Sutro weir, invented a number of years ago by the late Harry H. Sutro, and first applied to practical water measurement in October, 1908. A brief description and illustration of three of these weirs of one million gallons per day capacity each appears on p. 212 of the "Proceedings of the American Water Works Association," 1912, in a paper by F. H. Bruckenbach, describing the water-softening plant at Owensboro, Ky.

Owing to the sudden death of Mr. Sutro before any permanent record had been made of the calculations involved in the evolution of the mathematical expression for the shape of the weir opening, the benefit of his analysis of the problem was almost wholly lost. A number of weirs had been constructed, however, and were in use, and a carefully conducted test on one of small capacity showed the discharge to be in direct proportion to the head within an extremely small percentage of error. It thus fell to the writer's lot to analyze the problem anew and to derive the equation on which the shape of the curved side of the weir opening is based.

The Sutro weir differs from the shape suggested by Prof. Rettger only in two minor points. First, only one side of the opening is curved, the other being a straight vertical edge. Second, instead of employing the simple form in which the breadth of the opening approaches infinity as the head approaches zero, which shape, for obvious reasons, is undesirable practically, the base of the weir is limited to a convenient dimension and for a very small height the opening is rectangular. It has been found that for water the minimum height of this rectangle is about $\frac{1}{2}$ in.; for smaller heights the coefficient of discharge becomes erratic.

Referring to Fig. 1, the weir opening is seen to be bounded by the vertical sides AG and BD (BD being made as small as practicable), the horizontal crest AB, and the curved portion DFH above the rectangle $ACDB$.

Let Q_1 be the discharge through the rectangle $ACDB$ due to the head h above the top of the rectangle. Then

$$Q_1 = \tfrac{2}{3}\, b \sqrt{2g}\,[(h + a)^{\frac{3}{2}} - h^{\frac{3}{2}}] \qquad (1)$$

where a is the height of the rectangle. Next, consider a thin strip EF of thickness dy and length x, situated a distance y above CD; dQ_2, the discharge through this strip due to the head $h - y$, will be

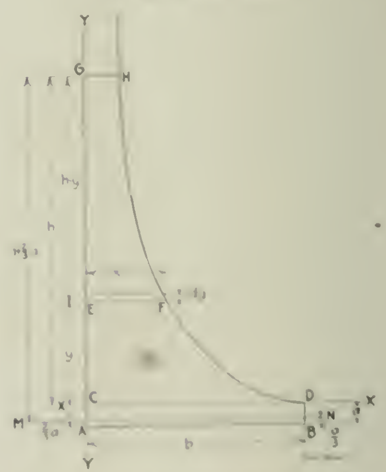
$$dQ_2 = \sqrt{2g}\,(h - y)^{\frac{1}{2}}\, x\, dy$$

The expression for the total discharge of the curved portion of the weir therefore is

$$Q_2 = \sqrt{2g} \int_0^h \sqrt{h - y}\; x\, dy \qquad (2)$$

If the total discharge of the weir be called Q, then

$$Q = Q_1 + Q_2 = \tfrac{2}{3}\, b \sqrt{2g}\,[(h + a)^{\frac{3}{2}} - h^{\frac{3}{2}}] + \sqrt{2g} \int_0^h \sqrt{h - y}\; x\, dy \qquad (3)$$



The object being to determine the shape of the weir such that the discharge is proportional to the head above a given datum line MN (Fig. 1), a general expression for the discharge Q is readily found. The datum line MN may be taken at any position between the base AB and the top CD of the rectangle. For convenience of calculation as well as of practical operation, the line MN is taken a distance of one-third the depth of the rectangle above AB.

The general expression for Q thus becomes,

$$Q = K\,(h + \tfrac{2}{3}\, a) \qquad (4)$$

where K is a constant whose value is to be determined.

Since the proportionality must hold at all points above the top of the rectangle $ACDB$, eq. (4) must hold when $h = 0$, in other words, when the depth of water is just equal to the depth of the rectangle.

Substituting $h = 0$ in eq. (3) and (4),

$$Q = \tfrac{2}{3}\, b \sqrt{2g} \times a^{\frac{3}{2}}, \text{ and } Q = \tfrac{2}{3}\, K a$$

whence

$$K = a^{\frac{1}{2}} b \sqrt{2g} \qquad (5)$$

Substituting the value of K in (4),

$$Q \tfrac{2}{3} b \sqrt{2g} \left(\tfrac{3}{2} h a^{\frac{1}{2}} + a^{\frac{3}{2}}\right) \qquad (6)$$

$$Q = \tfrac{2}{3} b \sqrt{2g} \left(\tfrac{3}{2} h a^{\frac{1}{2}} + a^{\frac{3}{2}}\right)$$

Equating the right-hand members of (3) and (6),

$$\tfrac{2}{3} b \sqrt{2g} \left(\tfrac{3}{2} h a^{\frac{1}{2}} + a^{\frac{3}{2}}\right) = \tfrac{2}{3} b \sqrt{2g} \left[(h + a)^{\frac{3}{2}} - h^{\frac{3}{2}}\right] + \sqrt{2g} \int_o^h \sqrt{h - y} \, . \, x dy$$

Transposing and simplifying,

$$\int_o^h x \sqrt{h - y}\, dy = \tfrac{2}{3} b \left[a^{\frac{3}{2}} + \tfrac{3}{2} h a^{\frac{1}{2}} + h^{\frac{3}{2}} - (h + a)^{\frac{3}{2}}\right] \qquad (7)$$

Expanding $(a + h)^{\frac{3}{2}}$ by the binomial theorem,

$$\int_o^h x \sqrt{h - y}\, dy = \tfrac{2}{3} b \left[h^{\frac{3}{2}} - \tfrac{3}{8} a^{-\frac{1}{2}} h^2 + \tfrac{1}{16} a^{-\frac{3}{2}} h^3 - \tfrac{3}{128} a^{-\frac{5}{2}} h^4 + \tfrac{3}{256} a^{-\frac{7}{2}} h^5 - etc.\right] \qquad (8)$$

It is evident that $x \sqrt{h - y}$ is identical with, and may be replaced by, a series which, where integrated with respect to y and after substitution of the limits, will give a resultant series identical with the right-hand member of eq. (8). It is evident on inspection that this condition is fulfilled when,

$$x = A_1 + A_2 y^{\frac{1}{2}} + A_3 y^{\frac{3}{2}} + A_4 y^{\frac{5}{2}} + A_5 y^{\frac{7}{2}} + etc. \qquad (9)$$

where A_1, A_2, A_3, etc., are constant coefficients whose values are to be determined.

Inserting this expression for x in $\int_o^h x \sqrt{h - y}\, dy$,

$$\int_o^h x \sqrt{h - y}\, dy = A_1 \int_o^h \sqrt{h - y}\, dy + A_2 \int_o^h \sqrt{hy - y^2}\, dy + A_3 \int_o^h y \sqrt{hy - y^2}\, dy + etc. \qquad (10)$$

Integrating separately each term of eq. (10),

$$\int_o^h x \sqrt{h - y}\, dy = \tfrac{2}{3} A_1 h^{\frac{3}{2}} + \tfrac{1}{8} \pi A_2 h^2 + \tfrac{1}{16} \pi A_3 h^3 + \tfrac{5}{128} \pi A_4 h^4 + \tfrac{7}{256} \pi A_5 h^5 + etc. \qquad (11)$$

It is seen that the powers of h (the only variable) in the right-hand member of eq. (11) are identical with the powers of h in the right-hand member of eq. (8); also that each of these series is equal to $\int_o^h x \sqrt{h - y}\, dy$, which justifies the use of eq. (9).

Equating the right-hand members of (8) and (11),

$$\tfrac{2}{3} b \left[h^{\frac{3}{2}} - \tfrac{3}{8} a^{-\frac{1}{2}} h^2 + \tfrac{1}{16} a^{-\frac{3}{2}} h^3 - \tfrac{3}{128} a^{-\frac{5}{2}} h^4 + \tfrac{3}{256} a^{-\frac{7}{2}} h^5 - etc.\right] = \tfrac{2}{3} A_1 h^{\frac{3}{2}} + \tfrac{1}{8} \pi A_2 h^2 + \tfrac{1}{16} \pi A_3 h^3 + \tfrac{5}{128} \pi A_4 h^4 + \tfrac{7}{256} \pi A_5 h^5 + etc.$$

Equating the coefficients and solving for A_1, A_2, A_3, etc.,

$$A_1 = b; \quad A_2 = -\frac{2}{\pi} a^{-\frac{1}{2}} b; \quad A_3 = \frac{2}{3\pi} a^{-\frac{3}{2}} b;$$

$$A_4 = \frac{2}{5\pi} a^{-\frac{5}{2}} b; \quad A_5 = \frac{2}{7\pi} a^{-\frac{7}{2}} b; \ etc.$$

Substituting these values in (9),

$$x = b - \frac{2b}{\pi} a^{-\frac{1}{2}} y^{\frac{1}{2}} + \frac{2b}{3\pi} a^{-\frac{3}{2}} y^{\frac{3}{2}} - \frac{2b}{5\pi} a^{-\frac{5}{2}} y^{\frac{5}{2}} + \frac{2b}{7\pi} a^{-\frac{7}{2}} y^{\frac{7}{2}} - etc.$$

$$= b - \frac{2b}{\pi} \left[\frac{y^{\frac{1}{2}}}{a^{\frac{1}{2}}} - \frac{1}{3} \frac{y^{\frac{3}{2}}}{a^{\frac{3}{2}}} + \frac{1}{5} \frac{y^{\frac{5}{2}}}{a^{\frac{5}{2}}} - \frac{1}{7} \frac{y^{\frac{7}{2}}}{a^{\frac{7}{2}}} + etc.\right] \qquad (12)$$

But,

$$\sqrt{\frac{y}{a}} - \frac{1}{3}\left(\sqrt{\frac{y}{a}}\right)^3 + \frac{1}{5}\left(\sqrt{\frac{y}{a}}\right)^5 - \frac{1}{7}\left(\sqrt{\frac{y}{a}}\right)^7 + etc. = tan^{-1} \sqrt{\frac{y}{a}}$$

Therefore,

$$x = b\left(1 - \frac{2}{\pi} tan^{-1} \sqrt{\frac{y}{a}}\right) \qquad (13)$$

which is the equation of the curve DFH with respect to the axes XX and YY.

To determine the shape of a weir of specified capacity either a or b, and h may be made suitable dimensions, and b or a found by substituting the proper quantities in eq. (1), Q_1 being proportional to the ratio of $\tfrac{2}{3} a$ to $(h + \tfrac{2}{3} a)$.

The values of all constants being known, values of x corresponding to given values of y may be found from eq. (13).

The Sutro weir has been used on a number of water-purification plants, being particularly adaptable to the control of proportional chemical-feeding devices. The patent is owned by L. M. Booth Co., of New York, on whose water softeners the weir is also used.

E. A. Pratt,
Assistant Chief Engineer, N. Y. Continental Jewell Filtration Co.

A Wonderful Pump

Sir—If by chance you think that there are no brilliant mechanical minds in the wild and wooly West, the following item from a local paper will refute such a view:

> There is now being exhibited a new pump which the inventor, James Peterson, of Provo Bench, claims will revolutionize the pumping systems now in operation. This new invention is so constructed that the water in a great measure lifts itself. The pump is composed of two pipes or outlets, which act as a balance, and when in operation, the pumps will run with one-half the power that is necessary under the present systems in use. Demonstrations of the pump are now going on in different parts of the state. In speaking of his new invention, Mr. Peterson stated that his pump would lift 100 lb. of water with 50 lb. of energy, while with the pumping plants now in operation it takes 100 lb. of energy to lift 70 lb. of water. Mr. Peterson has also invented a new gasoline traction plow, which works on the principle of a spading fork.

If, as claimed, the pump will develop 200% efficiency, it is more than likely that it will indeed "revolutionize the pumping systems now in operation." Neither can the brilliancy be questioned of the idea of using water so that it, "in a great measure lifts itself."

L. M. H.

Provo, Utah, Aug. 14, 1914.

Gate Structures for Irrigation Canals—Concrete as a material for gate structures in American irrigation canals is beginning to displace wood, its durability overcoming the disadvantage of higher cost. Bulletin No. 115 of the U. S. Department of Agriculture purposes to submit to engineers such designs for gate structures for controlling the flow of water in ditches or canal systems as are adapted to different localities. Small and medium-size structures, for the most part, are described in the new bulletin. It does not attempt to exhaust the subject, but merely gives examples of structures which have satisfactorily served the purpose for which they were erected. As regards material the opinion of the investigator seems to be that a structure of combined wood and concrete, using the latter for inaccessible parts and wood for easily replaced parts, is the best practice.

Righting a Tilted Grain Elevator

SYNOPSIS—The Transcona grain elevator of the Canadian Pacific Ry. has a storage house about 200x75 ft., consisting of 65 bins 93 ft. high on a foundation slab, all of monolithic reinforced concrete. This structure, weighing some 20,000 tons, settled on one side till it stood at an angle of 27°, because of compression of soft strata. Concrete piers have been sunk to rock to form a secure foundation, and by excavating beneath the high side the structure is being righted so that it will come to rest on these piers, but at an elevation lower than its original level. Similar foundation piers have been put under the adjoining working house of the elevator, the foundation which did not settle.

The extraordinary case of the settlement and tilting of the storage-bin section of a large grain elevator near Winnipeg, until it stood at an angle of about 27° from

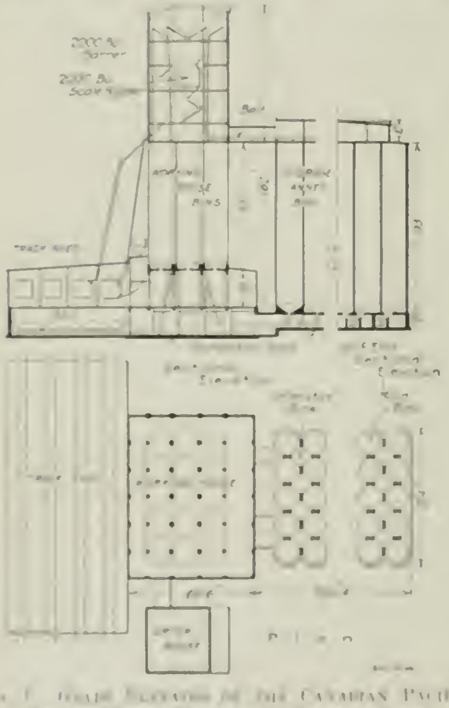

FIG. 1. GRAIN ELEVATOR OF THE CANADIAN PACIFIC RY. AT NORTH TRANSCONA, SHOWING THE ORIGINAL SLAB FOUNDATIONS

the vertical, was described in our issue of Nov. 6, 1913. We are now able to give some information as to the methods employed to check further movement, to restore the structure to a vertical position, and to place it on more stable foundations.

The grain elevator in question is that of the Canadian Pacific Ry., located at North Transcona, 4½ miles east of Winnipeg. It consists of two units, the working house, containing the cleaning, weighing and other machinery, and the bin house or the annex, consisting of the storage bins proper. The latter is the part which gave trouble. The structure was built by the Barnett-McQueen Co., of Fort William, Ont., in 1912, and was put into service in September, 1913. The entire structure is built of reinforced concrete, with the exception of a few brick curtain walls in the working house. Its construction is shown in Fig. 1.

The working house is 44x90 ft. in plan, and is 162 ft. high from the base of rail to the roof. It is provided with a 16-ft. basement in which the belts for transferring the grain from cars to conveyor boots are located, together with belts for transferring the grain from the annex to the working house. The first section of 20 ft. above ground is occupied almost entirely by the cleaning machines. Above this point there are 15 bins 13 ft. diameter, 70 ft. high, surmounted by several floors containing the garners and weighing machines, together with the necessary machinery for loading grain into cars. The general design is shown in Fig. 1.

The bin house consists of 65 circular bins 14 ft. 4 in. diameter, and 48 diamond-shaped bins occupying the spaces between the circular bins. The bin bottoms were originally at about ground level. All bins are 93 ft. high, and are surmounted by a cupola 10 ft. high, making the original height of this structure from ground level to roof about 103 ft. The bin walls are of concrete 6 in. thick, reinforced for bursting pressures and for vertical loads. The storage capacity is 1,000,000 bushels.

As regards the foundations, each of these buildings originally rested on a reinforced-concrete mat, designed to spread the loads over the entire area occupied. The under side of the mat of the working house was at a depth of about 15 ft. below ground level, while that of the bin house was 10 ft. below ground level. These foundations were independent of each other.

Borings were taken immediately after the failure and the soil found to be of a very treacherous nature, consisting of blue clay to a depth of 41 ft. below ground level. The upper 33 ft. of this clay was fairly stiff, but the lower 8 ft. was very soft and contained a great deal of water. Below the clay, from about 41 ft. to 50 ft. below ground level, was found gravel, together with a whitish clay which was very soft and contained a great deal of water. From 50 ft. to a depth of 55 ft. below ground level was found a layer of disintegrated limestone, and below this was bedrock.

These soil conditions appear to prevail over the entire district, and from work which has been done on the Red River at Winnipeg and on the same river at Kildonan it would appear that the bed of clay is very uniform in thickness. Load tests made before construction indicated that the soil could carry a load of 4 to 5 tons per sq.ft., while the actual load under the building was only about 3½ tons per sq.ft.

The elevator was first put into operation in the fall of 1913. In October, when the bin house is said to have contained 875,000 bushels of grain, a slight settlement was noticed but this was not of a serious nature. About Oct. 17, the settlement became very serious, and it is said that the building settled vertically a distance of nearly 1 ft., at which point it began to cant over in an easterly direction. The settlement continued for about

24 hr., until the whole building was leaning at an angle of about 27° from the vertical, and the westerly side of the foundation mat had sunk to an average depth of 29 ft. below its original elevation. At this point, movement ceased, the lower side of the mat having reached a stiffer stratum of the soil.

Fig. 2 shows the condition of the building after settlement, the conveyor cupola and roof structure having fallen off. At the right is the working house, with its track shed. Holes were cut in the bins and the grain removed, being delivered to cars by a temporary belt conveyor.

Strange to say, the working house was not seriously affected by the movement of the soil under the bin house. It suffered no damage beyond a few cracks in the walls adjacent to the annex, and there are no records which would show that any settlement took place in this building.

Soon after the failure, the Foundation Co., of Montreal, was called in to devise a scheme for underpinning the working house, the foundations for which it was feared might fail. That company was also asked to consider various means by which the bin house itself might be righted and restored to service.

After a number of conferences between the railway company's engineers and the officials of the Foundation Co., it was decided that the working house should be underpinned immediately by means of piers carried to bedrock. It was decided also that it was quite practicable to shift the bin house back into a vertical position, and when the actual moving was completed, to underpin it also by means of concrete piers carried to the rock.

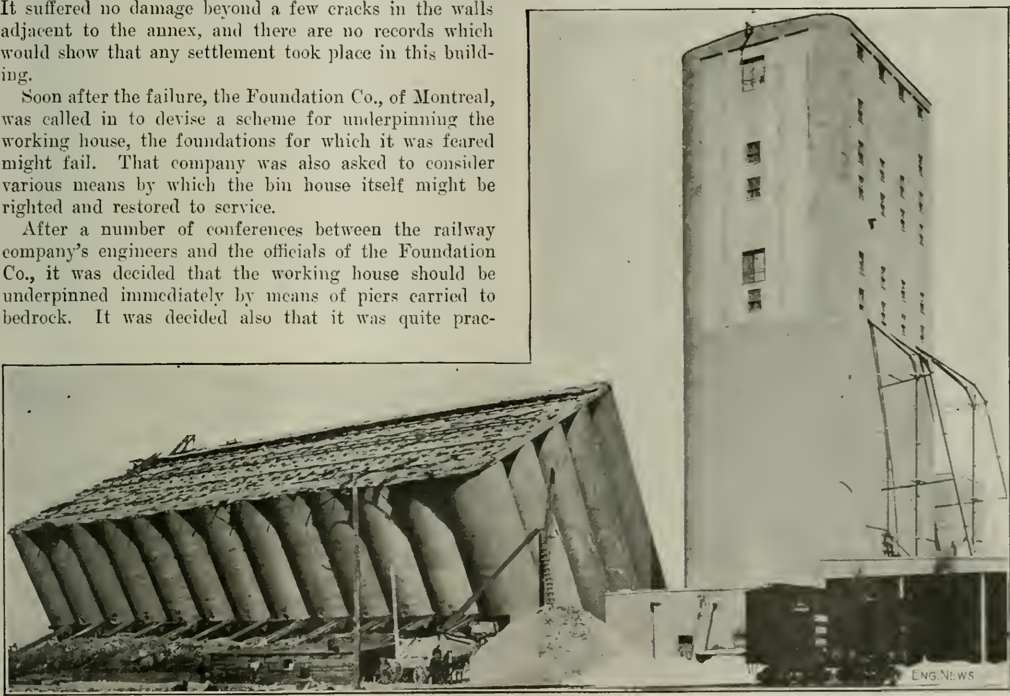

Fig. 2. The Storage Section or Bin House of the Elevator in Its Tilted Position, with Shoring in Place. At the Right Is the Working House

Underpinning the Working House

In January last, work was commenced on the underpinning of the working house. The scheme decided upon was to sink a pier under each column of the building. On account of the height of the building and the heavy column loads, it was necessary to shore the building completely before attempting to excavate under the columns themselves. In order to provide supports for the shoring, 16 small piers were sunk along the outside walls of the building, these piers being arranged to take the heels of the pusher timbers and to serve afterwards as supports for the outside walls.

At the westerly end of the building, four piers were sunk to rock in order to take the loads from the pushers at this point, these piers being located in such a position that they would serve as foundations for the columns of a possible future extension. A very complete system of heavy timber shoring was then installed, consisting of sets of 12x12-in. pushers heeling on the piers previously sunk and catching the heads of the columns immediately under the bin floors (Fig. 3). These timber pushers, together with the columns, the bin floors, and the foundation mat, formed a very effective truss system by which the load of the building could be transferred to the temporary piers.

Of the shoring piers above described, the first eight (located at the four corners of the building) were built by means of sectional cast-iron cylinders 4 ft. diameter, sunk to rock by excavating the material from the inside in the manner usually employed in sinking caissons. The shoring carried by these eight piers was then installed so as to give the building sufficient support to permit of the balance of the piers being put down as open wells with wooden sheeting held in place by interior iron rings, commonly known as the Chicago method. The piers inside the building were then commenced and were carried to rock by the Chicago method.

In order to get access to the under side of the columns for the purpose of sinking these piers, it was necessary to cut through the floor of the building adjacent to the column footings and to sink small shafts from which short tunnels were run to points directly underneath the columns. Fig. 3 shows the layout of the piers and the

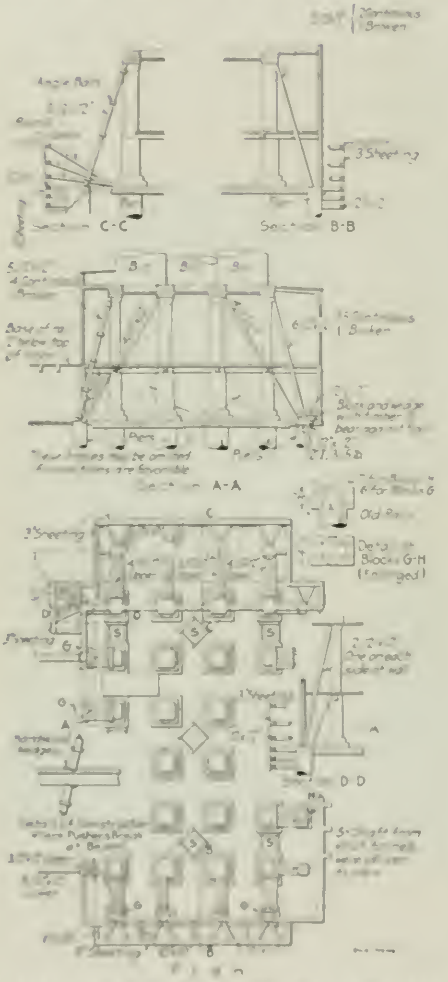

Fig. 3. Underpinning the Foundation of the Working House with Piers Carried to Rock

methods used in shoring the building, together with the location of the shafts and tunnels to the piers.

STRAIGHTENING THE BIN HOUSE OR ANNEX

Upon the completion of the underpinning of the working house, steps were taken to commence the work of straightening the bin house. In general, the scheme which is being adopted consists in righting the building by excavating the earth under the high side. It is expected that it will be quite practicable to bring the building back to a vertical position, although the structure will then be at a lower elevation than when first built. This fact, however, will not interfere with the operation of the elevator.

As stated above, it is the intention to provide new foundations for the bin house, these to consist of piers 7 ft. diameter, spaced approximately 15 ft. c. to c., and carried to rock. Fig. 4 shows the layout of these piers and shows also in general the position that the structure is expected to occupy after the completion of the turning movement. On all interior piers which are located under the "contacts" between the bins, the upper section of the pier is made 7 ft. square, so as to enable the loads to be properly transferred to the piers through the walls forming the passages underneath the bins. The exterior piers are provided with a corbel, heavily reinforced, so as to take the loads from the overhang of the bins, this corbel being extended about 4 ft. beyond the inner edge of the pier so as to minimize the effect of eccentric loads on the pier itself.

Fig. 5 shows the condition of the bins at the commencement of the turning operations, which were proceeded with in the following manner: A trench was first excavated along the high side of the building and along the ends, this being stepped off at the natural slope of the soil, and being carried to a depth sufficient to enable excavation to be carried on underneath the mat. The surplus material from this excavation was handled by means of dump wagons.

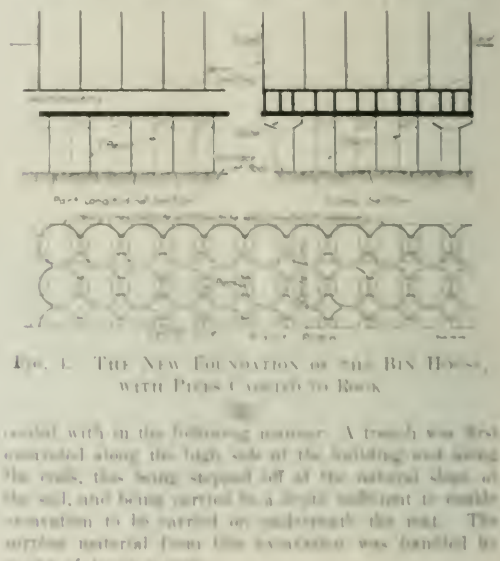

Fig. 4. The New Foundation of the Bin House, with Piers Carried to Rock

Work was then commenced on the sinking of the line of piers along the low side of the building, it being the intention to block the building temporarily from these piers so that they would form a fulcrum about which the structure might be rotated some 35°.

Excavation was then commenced under the mat itself, being carried out in the form of drifts, driven transverse to the longitudinal axis of the building, leaving a triangular core of earth between adjacent drifts. It was the intention that as the mat was dropped this triangular core would offer increasing resistance to the movement and that the whole operation could be controlled by gradually cutting away the earth from the sides of this core. The surplus material from the excavation under the mat was removed by means of belt conveyors, one of which is clearly shown in Fig. 5. The condition of the building preparatory to making the first movement is shown at the left in Fig. 6.

While work was being done on the line of piers under the low side and while the drifts were being driven under the mat, work was rushed on all of the other piers, it being the intention to have the piers completed before the structure had moved through the first 15°.

These piers under the annex are being sunk by the Chicago method, that is, by sinking open wells, with wood sumps from which the water could be handled by centrifugal pumps, thus materially lowering the general groundwater level.

At the end of July, 85% of the piers had been sunk and concreted and the building had been rotated about the low line of piers at the rate of about 4 in. per day, the total drop at the high side of the mat being about 5 ft.

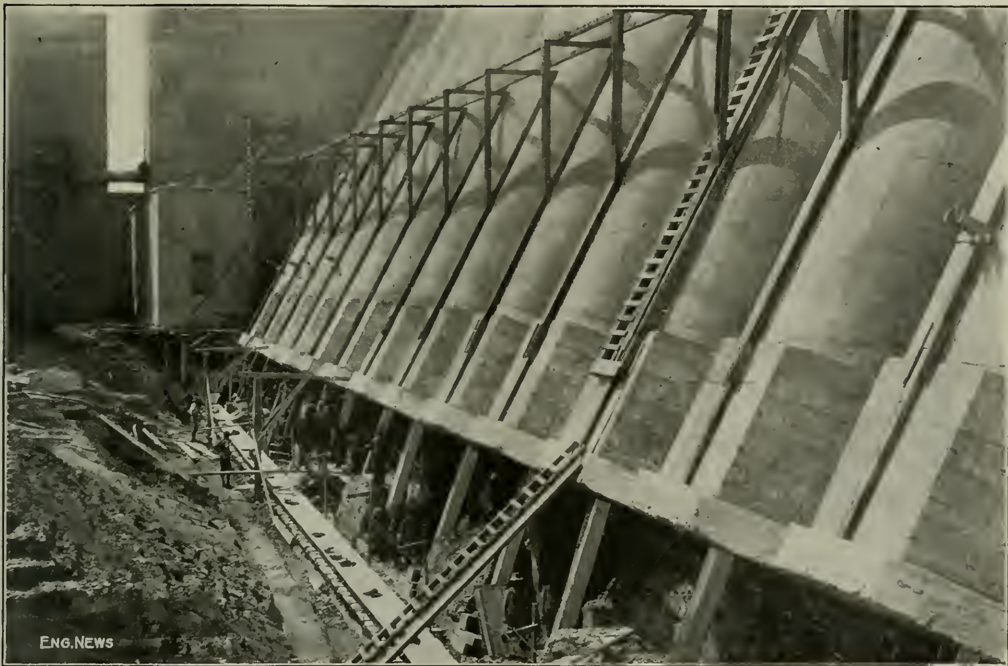

Fig. 5. Preliminary Excavation under the High Side of the Tilted Bin House of the Transcona Elevator, Canadian Pacific Ry.

lagging held in place by iron rings, which are removed as the pier is concreted. Considerable difficulty was experienced in the sinking operations on account of the large volume of water encountered in the gravel overlying the rock. This difficulty was more pronounced in the case of the first piers sunk, but the water was successfully controlled by using some of the piers as temporary The movement of the building is being controlled by the earth cores assisted by shoring screws and short posts under the mat, as indicated at the left of Fig. 6.

As stated above, it is the intention to thus drop the building about the line of piers under the low side through 15°, which will bring the structure into the position shown at the right of Fig. 6. This being accomplished, it is anticipated that the balance of the turning movement can be made about the center line of piers, the load being controlled by means of groups of heavy jacks on the two lines of piers under the low side. This arrangement is shown clearly in Fig. 6.

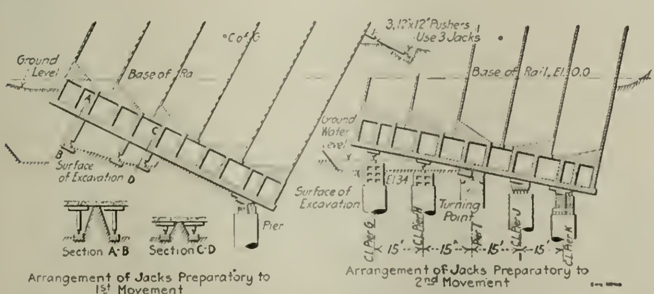

Fig. 6. Methods of Restoring the Storage House to a Vertical Position (but at a Lower Elevation)

During the progress of the work, it has been found that the movement of the structure can be controlled perfectly in the manner outlined above, and thus far the work has been entirely successful. Naturally in an undertaking of this kind, it is necessary to move carefully step by step, and in shifting a weight of some 20,000

tory, it has been deemed advisable to move very slowly and to anticipate as far as possible all points at which trouble may develop. We are informed that it now seems assured that the building can be straightened, and that all operations can be carried out substantially as originally planned.

The underpinning and straightening operations are being carried out by the Foundation Co. (Limited), of Montreal and Vancouver, Canada, and we are indebted to that company for information and drawings. The work is under the direction of J. G. Sullivan, Chief Engineer of the Canadian Pacific Ry. (at Winnipeg); and Frank Lee, Principal Assistant Engineer, is in charge of the work for the railway company.

In this connection, we may refer to the similar settlement of a reinforced-concrete warehouse building in Tunis (Africa), which was righted somewhat in the same way as described above, assisted by loading the high side of the floors. In this case, the building when righted stood at an elevation 15 ft. below its original level. This work was described in ENGINEERING NEWS, Apr. 25, 1907.

An Air-Lift Pump with "Booster" for Horizontal Delivery

A water-supply independent of the city mains was desired by the Fort Pitt Brewing Co., of Sharpsburg, Penn., and to meet this requirement it was decided to sink wells along the bank of the Allegheny River. There are three wells, 150 ft. apart. The nearest is about 1350 ft. from the [illegible] at the plant, and as the water was to be raised by the air-lift system some special means was required to force the water horizontally for this distance. For this service an air "booster" is employed. From the cistern a high-pressure pump delivers the water to an elevated tank.

The air-lift adopted is of the Sullivan type, in which a thorough mixture of the air and water is aimed at. This is considered to give less slippage of air and consequently higher efficiency, than the original Pohle plan of alternating "plugs" of air and water. The air (at 34 lb. pressure) is carried down outside the well casing in a 1-in. pipe, which at the bottom enters the elbow of the foot-piece or nozzle within the pipe. This nozzle, Fig. 2, is about 12 in. high, $1\frac{1}{2}$ in. inside diameter and it is pierced with rows of holes $\frac{1}{4}$ in. diameter, having an

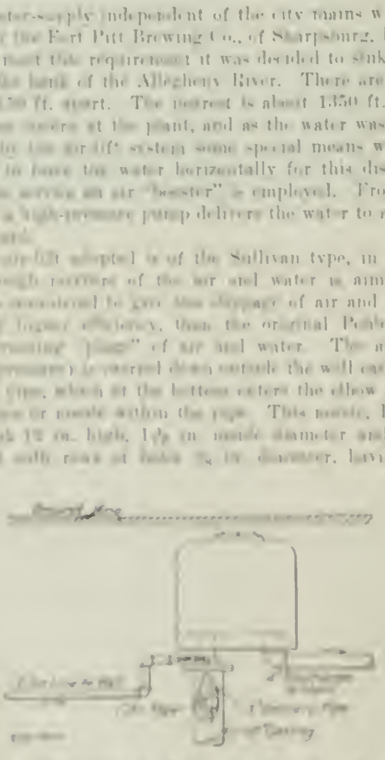

FIG. 1. BOOSTER AT HEAD OF AIR-LIFT WELL TO FORCE WATER THROUGH 1350 FT. OF HORIZONTAL PIPE

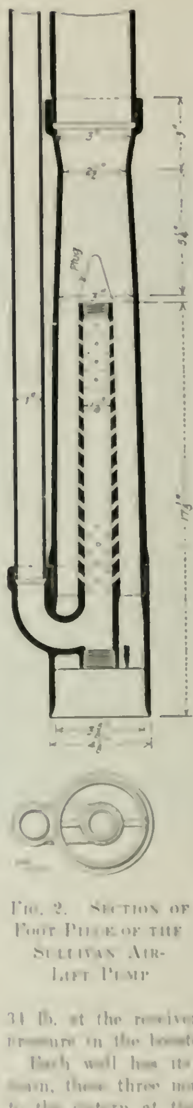

FIG. 2. SECTION OF FOOT PIECE OF THE SULLIVAN AIR-LIFT PUMP

upward inclination of 15°. There are four holes in each circle.

This arrangement insures a very thorough mixture of the air with the body of water. Above the nozzle the 3-in. delivery pipe is reduced to $2\frac{1}{2}$ in. diameter in order to increase the velocity, and above the foot-piece the diameter is increased to reduce the velocity at discharge.

The "booster" at the head of the well is shown in Fig. 1. It consists of a cast-iron chamber 30x30 in. with bottom connections to the well-delivery pipe and the discharge main. The delivery pipe extends up into the chamber and the stream of air and water discharged from it strikes a mushroom plate, which aids in the separation of air from the water. The end of the discharge main also extends up into the chamber and has its end slotted, while a drop pipe or sleeve over this end compels the water to pass upward before entering the pipe. A baffle-plate checks the splashing, and maintains comparatively still water around the discharge.

There is an open exhaust for the released air to escape to the atmosphere, but this is throttled by a valve so as to retain sufficient pressure above the water in the chamber to force it through the discharge pipe to the required distance. With the exhaust pipe full open it will discharge air and water, but the valve is closed until only air escapes. The operating pressure is 34 lb. at the receiver of the compressor, and the back pressure in the booster chamber is about 11 lb.

Each well has its own booster, and 4-in. discharge main, these three mains connecting with an 8-in. main to the cistern at the plant, where it discharges under water. The capacity of the cistern is about 18,000 gal.

Air is supplied by a straight-line compressor having a steam cylinder 12x12 in. and an air cylinder 14x12 in. This runs at 116 r.p.m., with a piston displacement of 248 cu.ft. of free air. The guaranteed capacity of pumping was 150 gal. per min., but the actual delivery (of the three wells) is 240 gal. per min. The theoretical horse-power is 10 hp., and with 26 i.hp. in the steam cylinder the efficiency (or relation of i.hp. to work done) is 40%.

The wells are 115 ft. deep, 10 in. diameter for 66 ft. and then 8 in. to the bottom. The strainer, which is located at the bottom of the 10-in. casing, is 10 in. diameter and 15 ft. long. The pumping head in the wells is 40 ft., and the elevation above the wells (including friction) is 15 ft., making a total lift or head of 55 ft. The

submergence of the foot-piece is 75 ft., or 58% of the depth.

Fig. 3 shows one of the boosters as installed temporarily, with the air-exhaust pipe extending above it. When completed, each booster and its pipe will be inclosed in a concrete chamber beneath the ground, the exhaust pipe being bent to discharge downward within the chamber.

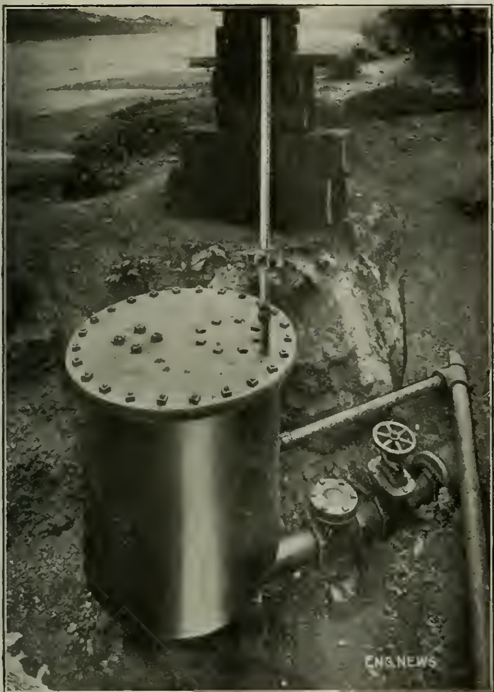

FIG. 3. BOOSTER CHAMBER ON AIR-LIFT WELL AT SHARPSBURG, PA.

The plant was designed by the Federal Engineering Co., of Pittsburgh, of which J. R. Kommer is President. The contract for the air-lift system and compressor was awarded to the Sullivan Machinery Co., of Chicago, and the details were worked out by John Oliphant, of that company, to whom we are indebted for plans and information.

Type of Boats for the New York State Barge Canal

The completion of the New York State Barge Canal is still some years away, but the prospective opening of certain branches is near enough to make necessary the consideration of the type of boat which will be best suited to the canal. A recent statement by the State Engineer and Surveyor, John A. Bensel, indicates that some difficulty is being met in planning the proper type of tow boats and barges. In the *Barge Canal Bulletin*, July, 1914, Mr. Bensel says:

A western manufacturing company, desirous of obtaining its raw material at a minimum of cost and of lessening freight charges on that portion of the finished product shipped east, recently made an investigation as to the comparative costs of rail- and water-borne transportation. The company found that it would not be desirable or economical to break bulk at any intermediate port and that the cargo vessel must be specially adapted, not only for safe carriage, but for cheap and rapid loading and unloading alongside warehouses or vessels.

The ship builders have found it impracticable to design a steamer that will satisfy the requirements of the Federal government for steam craft navigating the Great Lakes and also to keep within the limitations imposed by the Barge canal, such as restricted clearance of 15½ ft. under bridges and other fixed structures, at high navigable stage, the narrow width of 75 ft. in land sections and shallow depth of 12 ft.

The most promising solution of the problem for the company thus far devised is a fleet of two barges each 300 ft. in length and 40 to 43 in width, with an equal number of barges about 250 ft. long with 35 to 40 ft. beam, together with the requisite number of tugs about 50 ft. long, to tow one large and one small barge through the canals, and large sized lake tugs to tow a fleet of barges through the Great Lakes and rivers.

Boats having about 40 ft. beam cannot meet nor pass in the land sections of the canal where the bottom width is 75 ft. Numerous passing basins, where the canal prism is widened to at least 100 ft., will be necessary, if large sized boats are allowed to navigate the canals. Several such basins have already been constructed and there are also some natural formations of wide waters. Boats 300 ft. long can make all the curves in the canals, but as they will take up full width of channels while rounding the worst bends, they may have to slow down to a speed of about two miles an hour at those places.

It is likely that the largest number of vessels that will be built for canal use will be for fleet service and will be about 150 ft. long with a 22-ft. beam, that size permitting lockage of four at one time, one of the four being a power boat.

Another type of boat that will be used will be about 300 ft. long, the beam being from 40 to 43 ft. This type will probably be used for service on the Great Lakes. Undoubtedly most of the new boats will be of steel construction.

In vessels having a length of 300 ft., freight will be carried cheaper through the canal than in boats of smaller size. A single steamer could make better time through the new canal than a fleet of smaller boats.

Navigation of the land sections of the canal will probably be restricted to a maximum speed of about six miles an hour. The time for a single lockage will probably average 20 minutes.

A single steamer, while traffic is comparatively light, will make the run from Buffalo to Waterford in about 55 hours, but the average time will be about 72 hours for the 350 miles. In the Hudson River the time from Waterford to New York will be about 15 hours for the 150 miles.

Notes from Engineering Schools

A correspondence school for electric-railway men is being planned between the American Electric Railway Association and The International Correspondence Schools, Scranton, Penn. The courses will show general separation into mechanical- electrical- and civil-engineering branches—one being for young men in the shop, another for employees of the track and structures departments, and the third for those in power-house, substation and line work.

MUNICIPAL UNIVERSITY OF AKRON—A college of engineering has been established and five-year coöperative courses will be given. Applicants for entrance have been assigned to preliminary shopwork for this summer; regular instruction will begin in September. As usual, the students will be grouped in two sections alternating at work (commercial employment) and under instruction. Each school year will cover eleven months, one week vacation being allowed at Christmas and three weeks in late summer. Degrees of M. E. and C. E. will be given.

NEWS NOTES

A Tornado [illegible] Wilkes-Barre, Penn., on Aug. 2[illegible], killed five persons, injured [illegible] more and wrecked about [illegible]. The damage was confined to an area four blocks square.

Gas Explosions in Three Manholes at the foot of Market St., Philadelphia, on Aug. 1[illegible], lifted the covers with such force that one was broken when it struck the under side of the elevated-railway structure.

Many Forest Fires are raging in Montana and northern Idaho. Press dispatches state that more than 2000 national-forest fires have occurred this season, of which 1[illegible] have been in Montana and Idaho, 2[illegible] or more in California, and [illegible] in Oregon and Washington.

A Steamship Collision between the "[illegible]" of the [illegible] Transportation Co., from New York to Baltimore, and the British steamer "Westland" from Antilla to New York, occurred about 17 miles above the Northeast End Lightship off the Delaware Breakwater on Aug. 18. The bows of both vessels were damaged, but not seriously.

A Large Gasoline Tank Exploded in a garage in McConnelsville, Ohio, on Aug. 17, killing five persons and seriously injuring three others. The accident was caused by a spray of gasoline from the tank contacting with the hot engine of an automobile. All but one of the victims were in the garage at the time.

A Steel Lath-and-Plaster Ceiling Collapsed in the main operating room of the Keystone Telephone Co., Philadelphia, Penn., on Aug. 16, burying [illegible] telephone girls. Press dispatches state that firemen who examined the ceiling after its collapse stated that the plaster was spread too thickly over the laths, its weight pulling out the staples which supported the laths.

A Brick Foundation Wall Was Pushed In by earth pressure on the outside, at Allston, Mass., on Aug. 21, killing two men and severely injuring four others. The wall section which collapsed was about [illegible] ft. long by 10½ ft. high. A space [illegible] ft. wide between the wall and the sidewalk, and [illegible] were filling [illegible] space with [illegible] dirt when the accident occurred. A block of one-story stores is being erected on the site.

Broken Sewer Floods Montreal Subway Undercrossing—A [illegible] on Mill St., early in the morning of Aug. 16, broke the sewer from the Pointe St. Charles district in Montreal, [illegible]. The Wellington St. undercrossing [illegible] mile distance was flooded as a result and traffic was stopped there until [illegible]. The street [illegible] broke two [illegible] water mains [illegible] were shut off within a couple of hours. A new sewer is being placed on Mill St. parallel to the old one and at the point of the collapse the trench was open to a depth of [illegible] ft.

Two Building Collapses [illegible]

[illegible]

An Unexpected Loading [illegible]

[illegible]

and the rails, which fell in 2[illegible] ft. of water, have all been recovered.

Chinese Builders Win Hawaiian Contract—The War Department, Washington, D. C., awarded the contract for the construction of part of the army hospital at Fort Shafter, Hawaiian Islands, to a Chinese firm, on July 29. This is said to be the first time on record that the U. S. Government has let such a contract to a foreign firm, especially to Chinese, who are prohibited from competition with American labor in the United States. The Chinese firm was the lowest bidder for the hospital, at $119,[illegible].

A Municipal Coal Mine—The City Council of Sydney, N. S. W., has adopted a report of the city electrician, according to "The Commonwealth Engineer," to acquire a coal mine, for the use of the department, within a radius of 70 miles by rail from Sydney, and a reasonable distance from the seaboard. During the year 1913, the city paid £28,[illegible] for the coal used at powerhouses. It is estimated that this will increase to an annual charge of £50,000 in two years. It is stated that no proposition will be considered for a mine with less than 10,-000,000 tons in reach.

The Bureau of Public Utilities Research, proposed by Director of Public Works Morris L. Cooke of Philadelphia, and Mayor Blankenburg, is receiving wide support. A convention to organize the movement, to which representatives of city governments throughout the United States will be invited to send delegates, will probably be held in Philadelphia Nov. 12 to 14 next. The Bureau will have as initial trustees, Louis D. Brandeis, lawyer, of Boston; C. R. Van Hise, President University of Wisconsin, Madison; S. S. Fels, manufacturer, Philadelphia; F. W. Taylor, consulting engineer, Philadelphia; F. A. Cleveland, Director Bureau of Municipal Research, New York City; L. S. Rowe, Professor of Political Science, University of Pennsylvania, Philadelphia; C. F. Jenkins, publisher, Philadelphia; Felix Frankfurter, Professor of Law, Harvard University, Cambridge. (See "Engineering News," July 2, 1914, for outline of aims of this bureau.)

The Concrete Eating Crawfish has now arrived to rival the oft-heralded steel worm that devours railway rails. The Kansas City, Mo., "Star" of Aug. 11 tells all about him in the following words:

> A persistent crawfish found no difficulty in [illegible] the supposedly solid concrete floor of a sewer built by W. C. Mellies, president of the Kansas City Concrete Pipe Company.
>
> The picture [shown in the original, a pen and ink sketch of a sewer section some [illegible] ft. in diameter with a [illegible] crawfish of chicken lobster size in the immediate foreground —Ed.] was introduced as evidence in the taking of depositions in the damage suit of the Kansas City Concrete Pipe Co. against The Star.
>
> The sewer was a [illegible] concrete sewer on Brookside Boulevard, south of Sixty-[illegible] St.
>
> The "crawdad" had scooped out a large amount of concrete in its journey through the concrete wall.
>
> A hole made by another one of the [illegible] a block and a half away under similar conditions.
>
> It is to be hoped that the crustaceans do not travel in [illegible] battalions.

Flood Protection Work at Lafayette, Ind., [illegible] The Brown St. bridge [illegible] washed out by the flood of 1913, [illegible] The Main St. bridge [illegible] construction will probably be completed by the end of the year. This bridge consists of steel girders [illegible] concrete, replacing the old Whipple truss spans. [illegible] length in order to provide additional waterway, and the floor is [illegible] ft. above the original elevation.

The [illegible]

The Rebuilding Commission at Salem—At Salem, Mass., a good work is going forward under the direction of the Rebuilding Commission. [illegible] of fireproof building materials is being held and every effort is being made to develop a better understanding of the essentials of fire-resisting construction.

A great deal of space at the exposition is given over to educational work directed toward a more intelligent use of building sites. Many slides are exhibited to show the owner the best way he can use the typical [illegible]-ft. lot in Salem, how he can join with his neighbors to so place their dwell-

ings as to get a maximum of light, air, yard, etc. The Commission is directing an able campaign against the notorious "three-decker," showing how better two-story dwellings affording more room than the "three-decker" can be built at comparative cost and in the same space. The exhibition includes drawings and photographs and perspectives of some of the best known recent work in housing development. The work of this Rebuilding Commission is of great interest, showing how the community spirit, awakened and well-directed, can make for better living.

The Inter-River Drainage District of Missouri, comprising 127,500 acres, lying in Butler County, between the Black and St. Francis Rivers, has had plans for drainage and flood protection made for it by the Morgan Engineering Co., of Memphis, Tenn. The plans have been adopted by the Board of Supervisors of the District. A large percentage of the area outlined is subject to overflow from both of the rivers named. The works proposed include 58 mi. of levees, which would require 2,500,000 cu.yd. of earth. The levees would have a top width of 6 ft., side slopes of 2 to 1, and would average from 8 to 11 ft. in height. Dipper dredges could be used in the construction of the greater part of the levees, as also in the construction of a proposed system of ditches. The ditches would have bottom widths ranging from 12 to 55 ft., and depths of from 7 to 13 ft., and would aggregate 208 mi. in length. The ditch excavation would run up to some 8,000,000 cu.yd. of earth. For highway intersections 55 wooden bridges are proposed. The estimated cost of carrying out the project is about $1,250,000, or an average of $10.25 per acre of land benefited. The engineers named have completed the location survey for the ditches and leves, and assssors have been appointed for assessing the cost. As soon as the assessment roll is completed and confirmed by the court, which will probably be in about six months, it is expected that contracts will be let.

A New Passenger Station at Pocatello, Idaho, is to be built for the Oregon Short Line R.R., at a cost of $150,000 for the building and concourse and $175,000 for passenger yard trackage and other facilities. The station and tracks are at the street level. The building will be at the side of the tracks and 32 ft. from them, the intervening space being the concourse, which will be covered for a width of 22½ ft. The building will be 225 ft. long The central portion, 90x77 ft., three stories high, will have on the first floor the main waiting room (86x40 ft.) with ticket office, baggage checking counter, etc. The wings are 68x60 ft., two stories high, one containing the baggage and express rooms and the other containing the dining and lunch rooms. The upper floors will be occupied by the railway offices. There will be a hot-water heating system.

The building will be of fireproof construction throughout. The exterior will be of grey stone for the first story, and the upper stories will be of dark red brick, laid in ornamental pattern, with cut stone trim. The roof will be of asbestos shingles. The building was designed under the direction of E. E. Adams, Consulting Engineer of the Union Pacific System, and the construction work (which will be started at once) will be under the charge of Carl Stradley, Chief Engineer of the Oregon Short Line R.R. The architects were Carrere & Hastings, of New York, and the contract has been let to the Lynch-Cannon Engineering Co., of Salt Lake City, Utah.

The Need of an Investigation of an Additional Water-Supply for Philadelphia has been questioned by John C. Trautwine, Jr., formerly Chief of the Bureau of Water, in an open letter to Morris L. Cooke, Director of Public Works. Mr. Cooke some time ago asked the city council of Philadelphia for $15,000 to study the water-supply problem of Philadelphia, with special reference to an additional supply, including possible recourse to other sources than the present Delaware and Schuylkill River intakes within the city limits. Mr. Trautwine, in his open letter to Mr. Cooke, says:

(1) The works are now pumping, filtering and distributing at least twice as much water as the people can use and enjoy, and at least half of that water is thrown away, unused, by about one-fifth of the population, who thus victimize the other four-fifths.

(2) The waste could be stopped, the supply thereby rendered abundant, the use of water by the people increased, the quality rendered ideal, the cost diminished, and the present works relieved from overstrain, for a fraction of the amount which it is now proposed to expend immediately for works which would not then be needed. This would postpone, perhaps for twenty years, all necessity for enlarging the works.

(3) The water, brought to the city's present intakes by the Delaware and Schuylkill rivers, is absurdly ample for a dozen cities like Philadelphia.

(4) Therefore it is not necessary to seek other sources of supply; and no commission of experts is necessary to find out what is the matter with the city's water-supply.

In support of his contention, Mr. Trautwine quotes as follows from Director Cooke's reports for the years 1911 and 1912:

We are undoubtedly fortunate in lying at the junction of two such magnificent waterways as the Delaware and Schuylkill. But it is not wise to allow this good fortune to be given as an excuse for a profligate waste of water—a waste certainly amounting to one-half of all we use.

From a study of the results obtained from other cities, there is hardly a doubt that, if meters were placed on those properties wherein waste is detected, the consumption would be so reduced that a good supply could be maintained in all sections of the city.

PERSONALS

Mr. F. D. Nauman has been appointed Division Engineer of the Baltimore & Ohio R.R. at Garrett, Ind., succeeding Mr. John Tordella, promoted.

Mr. E. N. Sheffield, Assoc. M. Am. Soc. C. E., recently Civil Engineer in the Land Department of the Central R.R. of New Jersey, has opened an office for the general practice of civil engineering and surveying at Nashua, N. H.

Mr. Dan C. Miller has resigned as Instructor in civil engineering at the University of Michigan, to become Assistant Professor of civil engineering at the Agricultural and Mechanical College of Texas, College Station, Tex.

Mr. Leonard S. Doten, M. Am. Soc. C. E., formerly Civil Engineer in the office of the Quartermaster-General, U. S. Army, has been appointed Hydraulic and Sanitary Engineer in the same office, a new position recently created by Congress.

Mr. D. W. Gross, Assoc. M. Am. Soc. C. E., Engineer of Construction and Chairman of the Valuation Committee of the Atlantic Coast Line R.R., has been appointed Valuation Engineer and has been relieved of all duties as Engineer of Construction.

Mr. Walter F. Beyer, former Assistant Engineer in charge of the Division of Lighthouses, Panama Canal, has resigned from the canal service. Mr. Beyer went to the Isthmus in February, 1911, and had charge of the project of lighting and buoying the canal. Previous to going to Panama, Mr. Beyer was for many years connected with the United States Bureau of Lighthouses.

Mr. Arthur N. Winslow, recently Chief Draftsman of the Eastern Bridge & Structural Co., Worcester, Mass., has been appointed Professor of structural engineering at the University of Idaho, succeeding Mr. D. B. Steinman, Jun. Am. Soc. C. E., resigned, as noted in our issue of last week. Mr. Winslow is a civil engineering graduate of the Massachusetts Institute of Technology.

Dr. Karl Imhoff, Consulting Engineer, of Essen, Germany, will probably not be able to make his trip to the United States in September, as he had planned. It is stated by Mr. S. Fischer Miller, President of the Pacific Flush Tank Co., United States and Canadian representatives of Dr. Imhoff, that all communications addressed to Dr. Imhoff in their care will be forwarded as soon as relief from present difficulties in Europe will permit.

Mr. Harry C. D. Nutting, recently Assistant to the President of the Wisconsin Public Service Co. and the Wisconsin Ry., Light & Power Co., Milwaukee, Wis., has opened an office in the First National Bank Bldg., Milwaukee, as Public Utility Expert and Engineer. Mr. Nutting is a graduate in engineering of the University of Illinois and was formerly an Engineer with the Wisconsin Railroad Commission and Electrical Engineer at the U. S. Government Arsenal, Rock Island, Ill.

Mr. W. R. McCann, M. Am. Inst. E. E., Supervisor in the former Division of Erection, Panama Canal, has resigned and returned to the United States. Mr. McCann joined the canal staff in 1907 in the department of lock and dam construction. He resigned in 1908 to take a special two-year course in engineering at the University of Wisconsin, and he was reappointed to the canal service in 1910, as Assistant Engineer, First Division. Under the Electrical and Mechanical Engineer, Edward Schildhauer, M. Am. Soc. C. E., Mr. McCann designed the entire electric transmission system of the Panama Canal, and as Supervisor, has had charge of the installation. Before going to the Isthmus in 1907, he was for three years with the Chicago Edison Co.

OBITUARY

John [illegible] Barnes, a retired Mechanical Engineer, died Aug. 18, at his home in Brooklyn, N. Y., aged 76 years.

Thomas G. Carlin, a contractor, of Brooklyn, N. Y., died Aug. 21 at his home in that city. He was born in Brooklyn, Nov. 27, 1859, and was a brother of P. J. Carlin, Superintendent of Buildings of the Borough of Brooklyn.

Isaac Dell Barton, a former railway official, died Aug. 21, at his home in Flushing, N. Y., aged 80 years. He was at different times Assistant Superintendent of the New York & Harlem R.R., General Superintendent of the Long Island R.R., and General Superintendent of the Brooklyn Elevated R.R.

Henry K. Howell, M. Am. Soc. M. E., Industrial Engineer, Principal Assistant in charge of the organization department of Charles T. Main, M. Am. Soc. M. E., Mill Engineer and Architect, Boston, Mass., died at his home in Boston, Mass., Aug. [illegible]. He was born June 1, 1870 in Charlestown, Mass. His experience in mill work was extensive. He was engaged for several years in organization work in textile mills, for some time he was with Edward A. Buss, Consulting Engineer, of Boston, Mass., with Lockwood, Greene & Co., also of Boston, and for the past eight years had been associated with Charles T. Main.

Darius Miller, President of the Chicago, Burlington & Quincy R.R., died Aug. 23, at Glacier Park, Mont., following an operation for appendicitis. He was born at Princeton, Ill., Apr. 3, 1859. At 18 years of age he entered the employ of the Michigan Central R.R., as a stenographer in the general freight office. Later he served in various clerical capacities with the St. Louis, Iron Mountain & Southern Ry., the Memphis & Little Rock R.R. and the St. Louis, Arkansas & Texas Ry. He was Traffic Manager and later Vice-President of the Missouri, Kansas & Texas Ry., Vice-President of the Great Northern Ry., and Vice-President and President of the Chicago, Burlington & Quincy R.R.

Henry L. Oestreich, M. Am. Soc. C. E., Senior Division Engineer, Public Service Commission, First District, New York, whose death was noted in our issue of last week, was born in New York City, Feb. 18, 1878. After graduating from New York University in 1898, he entered the office of Charles B. Brush, Consulting Engineer, Jersey City, N. J., where he remained until 1897, during which period he had charge of much important work. From 1897 to 1900, he was with the Bureau of Highways of the Borough of the Bronx, New York City, as Assistant Engineer. Mr. Oestreich entered the service of the old Rapid Transit Commission in 1900, and his subsequent work was given in the obituary notice of last week. [From Robert Ridgway, Engineer of Subway Construction, Public Service Commission.]

John N. McClintock, for many years a civil engineer of Boston, Mass., died Aug. 12 at his home in Dorchester. He was born in Hallowell, Maine, 67 years ago, and was the son of a [illegible]. He was a brother of William E. McClintock, M. Am. Soc. C. E., former Chairman of the Massachusetts Highway Commission, and James Y. McClintock, M. Am. Soc. C. E., County Engineer of Monroe Co., Rochester, N. Y. He graduated from Bowdoin College in 1867, and for several years was an officer of the United States Coast and Geodetic Survey. Later he practiced civil engineering in Boston, and was President of the American Sewage Disposal Co. and the American Water Purification Co. He was the author of a "History of New Hampshire" and many magazine articles, and was at one time editor of the "New Hampshire Magazine." He is survived by a widow and a son, John Cook McClintock, a Boston architect.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN [illegible] MANUFACTURERS' ASSOCIATION.
Sept. [illegible]. Annual convention in New York City. Secy., J. [illegible], [illegible] St. and [illegible] Ry., Cleveland, Ohio.

AMERICAN MINE SAFETY ASSOCIATION.
Sept. [illegible]. Annual meeting in New York City. Secy., H. M. Wilson, Bureau of Mines, Pittsburgh, Penn.

AMERICAN FOUNDRYMEN'S ASSOCIATION.
Sept. 7-11. Annual meeting at Chicago, Ill. Secy., A. O. Backert, Cleveland, Ohio.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.
Sept. 9-11. Annual convention at Buffalo, N. Y. Secy., Will P. Blair, 832 B. of L. E. building, Cleveland, Ohio.

NATIONAL ASSOCIATION OF PORT AUTHORITIES.
Sept. 8-10. Annual convention in Baltimore, Md. Secy., Wm. Joshua Barney, 29 Broadway, New York City.

ROADMASTERS AND MAINTENANCE OF WAY ASSOCIATION OF AMERICA.
Sept. 9-11. Annual meeting at Chicago, Ill. Secy., L. C. Ryan, Sterling, Ill.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION.
Sept. 8-11. Annual convention in Nashville, Tenn. Secy., A. P. Dane, Reading, Mass.

NEW ENGLAND WATER-WORKS ASSOCIATION.
Sept. 9-11. Annual convention in Boston, Mass. Secy., Willard Kent, Narragansett Pier, R. I.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.
Sept. 15-18. Convention in Atlantic City, N. J. Secy., Clayton W. Pike, Electrical Bureau, Philadelphia, Penn.

ILLUMINATING ENGINEERING SOCIETY.
Sept. 21-2[illegible]. Annual convention in Cleveland, Ohio. Secy., Joseph D. Israel, 29 W. 39th St., New York City.

RAILWAY SIGNAL ASSOCIATION.
Sept. 22-24. Annual convention in Bluff Point, N. Y. Secy., C. C. Rosenberg, Times Building, Bethlehem, Penn.

ATLANTIC DEEPER WATERWAYS ASSOCIATION.
Sept. 22-26. Annual convention at New York. Secy., Addison Burke, Philadelphia, Penn.

INTERNATIONAL IRRIGATION CONGRESS.
Oct. 5-9. At Calgary, Alta. Secy., Andrew Miller, Industrial Commissioner, Calgary.

AMERICAN ELECTRIC RAILWAY ASSOCIATION.
Oct. 12-16. Annual convention at Atlantic City, N. J. Secy., E. B. Burritt, 29 West 39th St., New York City.

NATIONAL COUNCIL FOR INDUSTRIAL SAFETY.
Oct. 13-15. Annual "Safety Congress," at Chicago, Ill. Secy., W. H. Cameron, Continental Bank Building, Chicago.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.
Oct. 20. Convention at Los Angeles, Calif. Secy., C. A. Lichty, 319 North Waller Ave., Chicago, Ill.

Roadmasters and Maintenance-of-Way Association—The 32d annual meeting will be held Sept. 9-11 at the Auditorium Hotel, Chicago. Besides the various committee reports there are to be addresses by a number of railway engineers and officials, and an extensive exhibit of railway materials and appliances will be arranged in one of the large halls of the hotel. The president is T. F. Donahoe, B. & O. R.R.; secretary, L. C. Ryan, C. & N. W. Ry., Sterling, Ill.

New England Water-Works Association—The Committee of Arrangements has endeavored to make the 33d annual convention, to be held in Boston, Mass., Sept. 9-11, at the Copley-Plaza Hotel, of particular value to water-works superintendents, and to that end "superintendents' sessions" will be held on the afternoon of Sept. 10 and the morning of the 11th. Included in the rest of the program are the following papers: "Construction of Dams," A. E. Walden, Baltimore County Water & Electric Co.; "Electrolysis," E. B. Rosa, Bureau of Standards; "Allowable Leakage from Water Mains," E. G. Bradbury, Columbus, Ohio; "Lessons from the Salem Fire," Frank A. McInnes, Boston, Mass. Demonstration of water-main cleaning will be given. Liberal entertainment will be provided, with especial regard for the ladies. The secretary is Willard Kent, Narragansett Pier, R. I.

American Chemical Society—The convention scheduled to be held this fall in Montreal, Que., was canceled on Aug. 15 on account of the war between Great Britain and Germany. The following is quoted from a telegram sent C. L. Parsons, Secretary of the Society, by Prof. R. F. Ruttan, Chairman of the Montreal Committee of Arrangements:

The harbor, canals, etc., are under martial law. The excursions were off, as the steamboat company canceled our contract for steamers for the canals and harbor.

No German member of the Society would naturally come to British soil and all with German names would be questioned at the boundary. Many are even now turned back. We felt that the exclusion of so many prominent members of the Society was a high price to pay for a meeting here.

Any foreigners would be subjected to disagreeable formalities and conditions on coming here just now.

It would be impossible to attract to the Convention the slightest public interest in Montreal, outside a few dozen chemists. No one would come to the Conversazione or the garden parties we had arranged, and while there would surely be the feeling of good fellowship among ourselves, it would be overshadowed by the tragic war we are in at present.

Mr. Parsons states that "the present outlook is that the next meeting will be in New Orleans, Apr. 1-3, 1915." The office of the Secretary is in Washington, D. C.

Engineering News

VOLUME 72 SEPTEMBER 3, 1914 NUMBER 10

Seros Power Development, Lerida, Spain: Diversion Dam and Canals

By J. C. Stevens*

SYNOPSIS—The Seros Project, from which the Spanish city of Barcelona is to derive a supply of electricity, is of unusual interest from its 17 odd miles of supply canals, its long diversion dam, its four regulating reservoirs, its numerous control gates, its high-head power house, etc. The important features of diversion dam, canals, and gates are disclosed in this article, together with interesting notes on the construction work. The regulating reservoirs, earth dams and power house will be described in a subsequent article.

✕

The notable hydro-electric development described below is indicative of a great change in Spanish internal affairs, a few words on which are necessary to explain the reasons for such work as herein outlined.

One important cause of the disastrous effects of the internal dissentions and external invasions, which caused Spanish colonial power to slip away, has undoubtedly been the lack of attention to the development of natural resources. A large part of the Spanish population has been content with a hand-to-mouth existence and internal improvements have been extended to only moderate achievements. In recent years, however, relief from the burden of foreign possessions and foreign wars has given a great impetus to internal development. In Cataluna especially is this true. The backbone of national prosperity is agricultural development and nowhere is this more forcibly seen than in this district. Such advances have induced material advances in all other lines of activities: manufacturing industries have sprung up on all sides in a country where labor is yet comparatively cheap and raw materials plentiful.

Lower Concrete-Lined Canal; Seros Power Development, Lerida, Spain

Hence, the existing industries, the latent possibilities for further advance, the well developed agriculture, and all the attendant necessities for transportation and manufactured articles, render Cataluna a fruitful market for commercial power.

At almost the exact spot of one of Cæsar's important operations against Pompey (49 B.C.) is the work herein described. Cæsar found his enemies at Lerida on the banks of Rio Segre (called "Llerda" on the "Sicorio" in his *Commentaries*). During the 40 days' fight that fol-

*Spalding Bldg., Portland, Ore (formerly Project Engineer, Ebro Irrigation & Power Co., Ltd., Barcelona, Spain).

Fig. 1. General Plan and Profile of Seros Project

[...]owed, Cæsar diverted the river into several channels, each 30 ft. wide, and so reduced the volume of water in the main river as to render it fordable for his cavalry. In this manner he surprised his enemies in their camps, completely routed them, and closed a campaign as remarkable for its brevity as for its success. Where Cæsar diverted this river, the modern engineer has done likewise but for the peaceful purpose, then unknown, of generating electricity.

This development is in the hands of the Barcelona Traction, Light & Power Co., through its subsidiary, the Ebro Irrigation & Power Co., Ltd., which has under way three hydro-electric projects on Rio Segre and its principal tributary, Rio Noguera Pallaresa: (1) The Gerri project; (2) the Talarn Dam and Pallaresa Canal; (3) the Seros project. The first was started as a 3000-hp. temporary plant for construction service but has become a 4000-hp. permanent station and has been in operation since February, 1913. Near Talarn, a concrete dam 86 m. (282 ft.) high will impound 210 million cubic meters (170,000 acre-ft.) in a river valley; at the dam is to be a power house and tail water carried 18 km. in canal to a second station. The Talarn dam was 10% completed on May 1, 1914. The Gerri and Talarn sites are adjacent and some 135 km. northwest of Barcelona; the Lerida project is 80 km. southwest of Gerri and 110 km. east of Barcelona. The power generated will be largely used in Barcelona and outlying districts. Transmission lines connect the two projects and from a mid-point branches the Barcelona line.

The present article (and the subsequent one) will deal solely with the Seros project which was completed in April, 1914. The project consists briefly of (1) a diversion dam and intake structures to pass a flood of 157,000 sec.-ft., and divert 2120 sec.-ft. for power purposes; (2) an upper canal 11.8 miles in length lined throughout and leading to (3) the regulating reservoirs created by seven earth dams and giving an available daily storage of 2210 acre-ft.; (4) a lower canal 2.62 miles in length, exclusive of reservoirs, with a capacity of 1940 sec.-ft.; (5) forebay and penstocks; (6) the power house and transformer station where four 16,000-hp. turbines are installed and where the voltage is raised from 6000 to 110,000 for transmission to Barcelona; (7) a tailrace that returns the waters to the river.

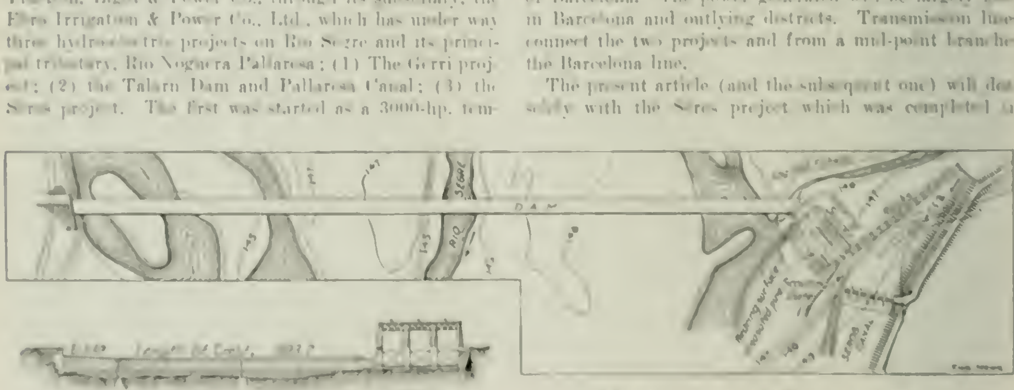

Fig. 2. Diversion Dam and Intake

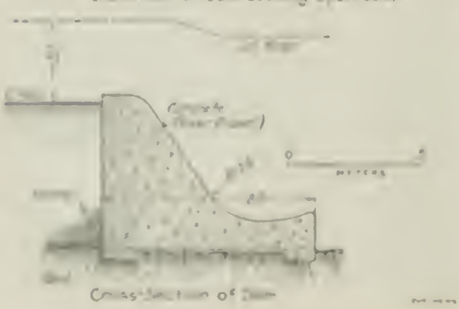

Fig. 1 is a general map of the Seros Project and a condensed profile of the power canal. The total length from diversion dam to tailrace is 28.4 km. (17.6 mi.). The total natural fall in the river between these points at low stage is 52 m. (170.6 ft.).

Upper Canal

Headworks—The general arrangement of the dam, intake, racks, sluice gates and canal gates is shown in Fig. 2. As the river carries considerable gravel at time of flood, the three large sluice gates are placed in such a manner as to scour out any accumulation of débris in front of the racks. These gates are 8.0 m. (26.25 ft.) long by 5.7 m. (18.70 ft.) wide with a clear lift of 7.0 m. (22.97 ft.); they are of the Stoney type, hand operated.

Fig. 3. Sluice and Canal Gates

The floor of the discharge channel in front of the sluices is of creosoted pine 6 in. thick, held in place by 45-cm. (17.7-in.) I-beams partly embedded in the concrete. The planks lie in the direction of the flow of water and are so arranged as to be readily replaced when worn.

The removable racks, 30 in number, are placed in 15 bays as shown in Fig. 2. The rack bars are a special type, spaced 15 cm. (5.9 in.) apart in panels 2.0 m. (6.56 ft.) wide. A traveling differential chain block is used to elevate them for cleaning or repairs.

The intake gates are six in number, also of the Stoney type, 3.4 m. (11.15 ft.) long by 6.0 in. (19.68 ft) high. with a lift of 3.8 m. (12.47 ft.), to be operated by hand. The bottom of the intake forebay has an inclination of 1.5% towards the canal gates. Just in front of these gates is a sand trap and a sluice gate to return to the river the débris that may pass the racks.

Overflow Dam—The dam is of the ogee overflow type, shown in Fig. 2. The foundation is a fairly hard sandstone of varying thickness. The surface is very irregular and heel and toe trenches are excavated into it as shown. Immediately below this sandstone is a stratum of indurated clay varying from 5 to 15 ft. in thickness, and practically free from seams.

No apron was built below the dam as it was decided to wait until the effect of overflowing water on the river bed below the dam could be studied; then if necessary, a protecting apron will be added. This will not be difficult as all ordinary water can be diverted into the canal or passed through the sluice gates and the toe of the dam unwatered.

During construction, the plan was first tried of driving a row of steel sheet piling in line with the upstream face in order to reduce excavation and serve as a cutoff, but the plan was not successful and was abandoned. The piling did not reach solid material but was bent and doubled so badly by the small gravel that most of it had to be removed by hand before the excavation could be completed. No serious difficulty was encountered in excavating by the ordinary methods in open trench and unwatering by motor-driven centrifugal pumps. The river channels were diverted by timber and stone coffer-dams to alternate sides of the stream bed and finally through the large sluice gates while the closure was made.

The total length of the overflow proper is 393.2 m. (1290 ft.) and the logway opening is 4.5 m. (14.8 ft.) with a low buttress between them of 3.5 m. (11.5 ft.), making a total length between abutments of 401.2 m. (1316 ft.). The dam is capable of passing a maximum of 3750 cu.m. per sec. over the ogee section, 650 through the sluice gates and logway, and 60 into the canal—or 4460 (157,000 sec.-ft.) in all. Fig. 3 shows the completed canal gates and sluice gates.

Power Canal—The first 19.2 km. (11.8 mi.) of the power canal has a grade of 0.00015 and a capacity of 60 cu.m. per sec. (2120 sec.-ft.) and is concrete lined throughout. Fig. 4 shows the type sections for this canal. It will be noticed that these approach the "economic section" i.e., maximum capacity for minimum perimeter and cross-sectional area. This was adopted even at the expense of deep excavation in order to minimize right-of-way and lining costs.

The upper canal for about half its length traverses intensively cultivated lands and a complicated network of irrigation and drainage ditches. In order to pass these ditches without disturbing existing conditions, small inverted siphons were used. In all, there are 43 siphons in the upper canal. These were made of thin steel pipe, with stove-pipe joints, placed in a trench and surrounded by concrete. At the entrance to each is a settling basin, concrete lined, and a grating which prevents floating trash from entering the siphon. In nearly all cases, the velocity is sufficiently high to prevent sedimentation. If, however, they do silt up, they are readily cleaned by passing a cleaning rod made of spring-steel bars smoothly joined in lengths of 14 ft. These act as a needle which is pushed

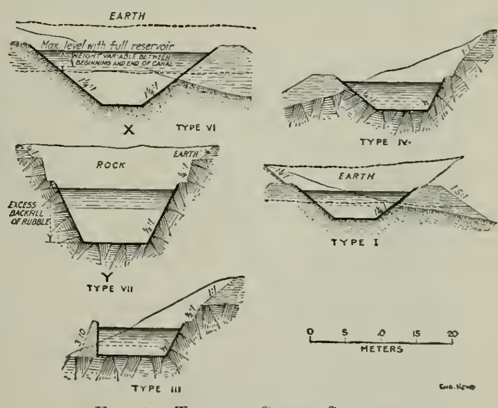

Fig. 4. Typical Canal Sections
(Sections X and Y for Lower Canal)

through the mud or trash and by means of which a rope is drawn through the siphon. To the rope is attached a series of buckets on a chain to remove silt and finally a spherical brush is drawn through, which completes the cleaning.

CANAL LINING—As indicated in the type sections, Fig. 4, the lining is of concrete 10 cm. (3.93 in.) thick. The mixture used was 1:3:6 cement, sand and river gravel (gravel screened to pass in any direction through a 2-in. ring). Attempts were made to place this lining without forms, but the plan was abandoned as it was found to be impossible to place the 4 in. of concrete on a slope of 1¼ on 1 without making it so very dry that its impermeability was seriously impaired.

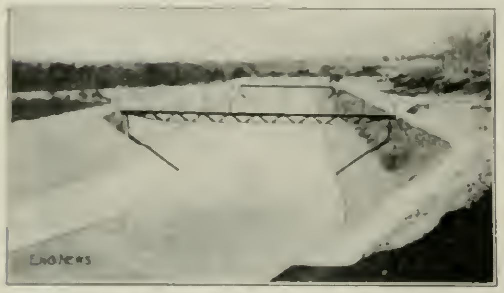

FIG. 5. UPPER CANAL HALF LINED

The lining was first carried to 3 m. vertical height only, in order to allow the made banks to settle as long as possible before lining. The remaining 1.7 m. was placed after water was in the canal. Fig. 5 shows a section of canal completed except for the upper strip of lining.

Part of the lining was let by contract and part was done by the company. Figs. 6 and 7 show the forms used by one of the contractors, and a sample of the finished surface. In this system the form boards were placed from the canal side of the [illegible] uprights. This was advantageous in that the trimmed slope was not touched and hence the green concrete was kept free from dirt that would otherwise be knocked onto it. This system also had the advantage of being more elastic, as one side could be lined at a time and thus the lining gang could follow the slope trimmers more closely. The most rapid work, however, was done by company forces using the system shown in Fig. 7. At first continuous mixers were used but they could not compete either in cost or quality of work with hand mixing, and they were therefore abandoned. In the design of the canal, a coefficient in Kutter's formula of n = 0.015 was used for concrete surfaces.

STOP LOGS AND WASTE GATES—At three nearly equally distant points on the upper canal, stop-log structures (see profile, Fig. 1) are provided by means of which the water in any section may be held if necessary. These [illegible] and [illegible] their chief purpose during the [illegible] of the canal. In each section also there are waste gates with discharge capacity aggregating 17 cu.m. per sec., with the canal full, by means of which any section may be [illegible].

LOWER CANAL

[illegible] above the power station the canal becomes a series of [illegible] some of which were closed by earth dams to create four regulating reservoirs. The disposition of these is shown in Fig. 1. These four reservoirs are connected by a lined canal having a net length, exclusive of reservoirs, of 4.22 km. (2.62 mi.) and a capacity at low reservoir of 120 cu.m. per sec. (4240 sec.-ft.), leading to the penstocks of the power house. The bed of this canal has a grade of 0.00026 while the top of the embankment is level at an elevation 1.0 m. above the maximum operating height of water in the upper reservoir. In this manner the head due to fluctuations in the reservoirs is not lost. In designing this canal, the velocity head in the canal was assumed to be lost at the entrance and reproduced anew at the exit of each of the four reservoirs outlined above.

Typical cross-sections of the lower canal are shown in Fig. 4 (marked "X" and "Y"). The same thickness of lining (3.9 in.) is used in this as in the upper canal. Fig. 9 shows lining in progress and gives an idea of the size of the canal and its great depth relative to its bottom width. This type was selected to facilitate control of the elevation of water surface in the reservoirs from the power house and to make the canal responsive to the fluctuating demands upon it.

This canal is provided with a special stop-log structure at its upper end where it leaves the first reservoir (see Fig. 1) and a set of four waste gates just before entering the forebay. By means of these, the storage water may be held in the reservoir and the lower canals and reservoirs emptied, or the water may all be passed through the canals and reservoirs and returned to the river without passing through the power house. These stop logs are of interest. The channel is divided into three portions by two piers

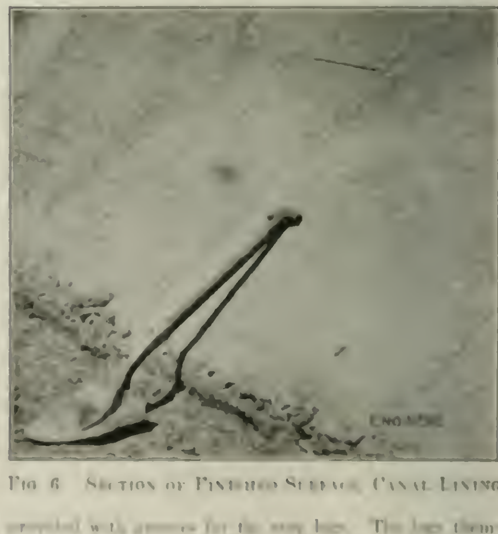

FIG. 6. SECTION OF FINISHED SURFACE, CANAL LINING

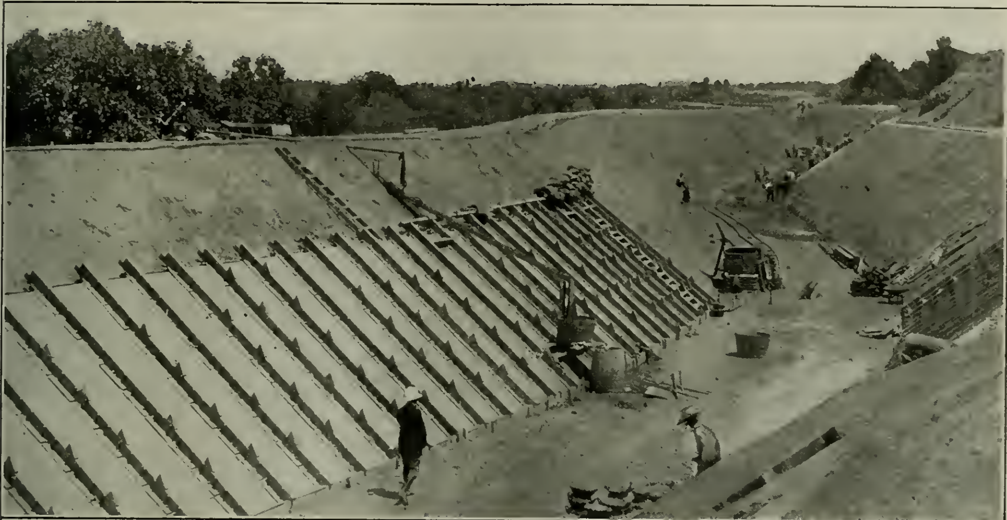
provided with grooves for the stop logs. The logs themselves are made up in leaves 15×1¼ ft. each, of 12-in. timbers, bound with angle irons and fitted at the ends with rollers. [illegible] plates project upstream at right angles to the stop logs and bear against an angle set in the stop-log grooves to prevent the excessive leakage that would otherwise occur.

These stop logs are suspended in the grooves by cables provided with a trip, by means of which they may be

dropped instantly into place. Provision was planned to force the logs down by suspending other logs to channel columns that would bear on the stop log that had been dropped, but it was found that the momentum the log gained before striking the water was usually sufficient to carry it to its seat. Fig. 10 shows the structure (combined bridge and stop) with one opening closed, and three stop logs suspended in each of the other openings, ready

course, could not be avoided, and on account of the comparatively thin lining it was necessary that the water be raised slowly in order that the effect of this settlement could be observed and any needed repairs made at once. It was observed on some of the higher embankments that the earth settled inwards toward the canal, the first evidence being a crack between the lining and the embankment. As fast as these cracks opened, drill holes were made be-



FIGS. 7 AND 8. PLACING THE CONCRETE LINING IN THE UPPER CANAL, SEROS PROJECT
(Fig. 7. Contractor's method. Fig. 8. Method of company force.)

to be dropped. As each leaf weighs two tons, a traveling chain block, shown in the figure, was necessary to handle them. This arrangement is temporary and more permanent gates will be installed later.

TESTING OF CANAL

The filling of the canals was accomplished with no serious consequences. Settlement of the earth banks, of

hind the lining with long drills at intervals of about 18 in., and an almost liquid puddle of clay and water poured into them. In this manner, the support for the lining was maintained and the lining preserved intact. As soon as the bank had taken its settlement no further difficulty was experienced.

Very little lining was broken by settlement, and wherever it did occur, it could nearly always be traced to poor

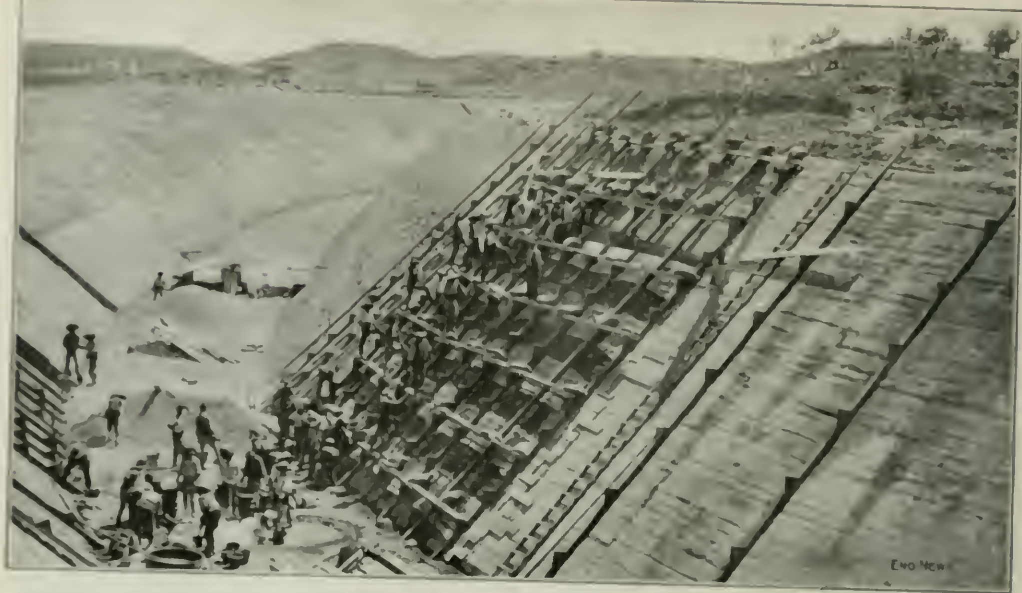


Fig. 9. Lining the Lower Segre Canal

conduit between the upper and lower strips of lining. In spite of eternal vigilance and inspection, the upper strip of lining was begun in a few places before the old surface had been properly squared and cleaned, with the result that when settlement occurred, the upper strip of lining would be taken with the earth, breaking or cracking at the joint. Repairs of this joint was necessary in not over 200 m. of its length, which is very little, considering that this joint was about 15,000 m. long. In all, not over 2000 m. of embankment required treatment after settlement.

Work on the whole project was carried through with speed. Active construction started in January, 1913, and water reached the station forebay Mar. 10, 1914—in 15

Fig. 10. Stop-Log Structure, Lower Canal

months. The right-of-way covered 317 hect. ([illegible] acres); the excavation, inclusive of borrow for earth dams was [illegible] cu.yd.; [illegible] cu.m. ([illegible] cu.yd.) of masonry and concrete were placed. The various gates and mechanisms came from Ransomes & Rapier, Ltd., of London; racks and screens were made by [illegible] and Konegan of Zurich. Practically all the structural steel was furnished by the Blaw Steel Construction Co., of Pittsburgh, Penn., U. S. A.

Organization

The work was carried out by the Ebro Irrigation & Power Co., Ltd., under the supervision of the Pearson Engineering Corporation, Ltd., of New York City. The following officials were in charge of the work: F. S. Pearson, President; A. W. K. Billings, Vice-President and Managing Director; Fred. W. Abbot, Manager of Construction; J. A. Sargent, Chief Engineer.

The work was executed under the inspection of the Public Works Department of Spain: Sr. Don José Bares, Chief Engineer for the Province of Lerida.

Checking a Landslide in a railway cut by breaking up the slope with massive blocks of concrete built in trenches running up the slope was practiced with success on the [illegible] & [illegible] Ry. in Switzerland. A sidehill cut had been made through an ancient landslip, the material consisting of clay and loam mixed with boulders and tree trunks, underlaid by a bed of [illegible]. A longitudinal crack about [illegible] ft. long appeared in the slope of the cut, and similar cracks developed in the ground above the edge of the slope, while 33 ft. from this was a main road. A retaining wall was proposed, but it was evident that this would be overturned or carried away before the concrete could set. As an emergency measure, massive concrete blocks were built in the slope, the excavations being carried into the hard material over which the loose mass was sliding, so that the blocks could not move down the slope.

Four blocks, 33 ft. apart, were built, but as the slide continued to squeeze out between them two additional intermediate blocks were built. The slope then stood, but the pressure was so great as to partly raise the blocks, revolving them on their lower ends so that they tended to approach a steeper slope. One block moved outward [illegible] in. at the top, its foot remaining stationary. The trouble was due to water in the soil, but there was no time to put in any drainage system, and some immediate action was necessary in view of the main road above the cut and the possibility of starting a slide of the whole slope of the mountain above the cut.

Electric Shifting Locomotives on a Cleveland Ore Dock

At the ore-unloading plant of the Ohio & Western Pennsylvania Dock Co., in Cleveland, Ohio, electric locomotives are used for spotting the cars underneath the unloading plant. When an ore vessel is brought alongside the pier, its hatch covers are removed and the 17-ton grab buckets at the bottom of the traveling legs are dropped into the hold and pick up a load of ore. They

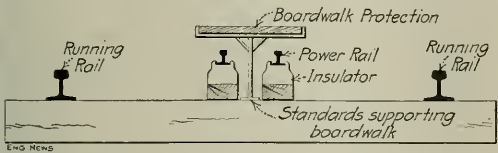

Fig. 1. Cross-Section of Track for Electric Switching Locomotive, Showing Protected Electric Conductors at the Ore-Unloading Plant of the Ohio & Western Pennsylvania Dock Co., Cleveland, Ohio

laid in the center of the track and covered by a board walk so that there is no danger of accidental contact with these rails. The accompanying cross-section makes the arrangement clear.

To enable the locomotive to move the cars on the track parallel with that on which the locomotive runs, a heavy braced arm projects from the side of the locomotive and can be rotated on a horizontal axis so that the arm can either be held vertical or can be dropped so that its projecting end comes against the poling iron on the end sill of the car. These steel arms are lowered or raised by compressed air and are under control of the operator in the locomotive cab. Thus the operator can drop this arm between any two cars and work the train of which they are a part forward or backward along the track. It will be seen that by this arrangement of switching the danger which accompanies the common use of poling locomotives on parallel tracks to the cars to be moved is obviated.

The electric locomotives were built by the Baldwin Locomotive Works and are equipped with Westinghouse motors and electrical machinery. They have a total weight of 25 tons carried on four wheels. We are informed that the three electric locomotives in this plant

Fig. 2. Three Views of the Electric Shifting Locomotive

then rise out of the hold and are traversed inward until they can drop their load into a 50-ton weighing hopper. As soon as the hopper is filled, a valve is opened and its contents are discharged into an ore car on the track below.

It is necessary to accurately spot the cars beneath the ore hopper to prevent the dropping of ore between the cars and this spotting has generally been done by heavy switching locomotives. The difficulty with this system is that the engineer on the switching locomotive at the end of the train cannot see well where to place the car and has to be governed by signals and it is difficult to accurately move a long train of cars by a locomotive at the end. In addition, the smoke and gas from the locomotives are very injurious to the steelwork of the unloading plant. These difficulties have all been overcome on the docks in question by the installation of a narrow-gage track between each pair of railway tracks on which narrow-gage tracks run electric shifting locomotives. These locomotives take their current from a pair of live rails

moved last year 60,000 cars on this dock. The general plan of the use of these electric switching locomotives on parallel tracks, with the movable arms for operating the cars, was the idea of Chas. E. Cole, superintendent of the dock company, and we are indebted to him for the information and illustrations here presented.

⁂

Triplex Safety Glass—By-Triplex Glass is built up by layers of glass and sheets of celluloid (xylonite), and is manufactured by the Triplex Safety Glass Co., Albemarle St., W., London, England. On June 27 its resisting properties were thoroughly tested. An army service rifle and ammunition were used at a range of 300 yd., with the following results: (1) 1¾-in. glass. Bullet struck the glass almost in the center, but only penetrated the first thin layer, $\frac{1}{16}$-in. thick. The intermediate and back sheets were cracked; the back, however, remained smooth. (2) 1⅜-in. thick. Bullet struck bottom left-hand corner, penetrating one layer of glass and one of celluloid without going farther. (3) A 1¼-in. piece was badly damaged, but as not penetrated.

An important quality of this glass is that although it may be badly cracked it still remains airtight and waterproof, on account of the celluloid between the layers of glass.

Water Filtration and Softening Tests at Cleveland, Ohio

By Hippolyte Gruener*

SYNOPSIS—A working-scale coagulating basin and mechanical filter were constructed and tested at Cleveland to obtain information for guidance in designing a mechanical-filtration plant. The tests have included (1) alum; (2) ferrous sulphate and lime, and (3) lime alone as coagulants, as well as lime for softening. Boiler and laundry tests have been made as well as studies of after deposits and growths on the filter sand. Slow sand filtration has also received attention.

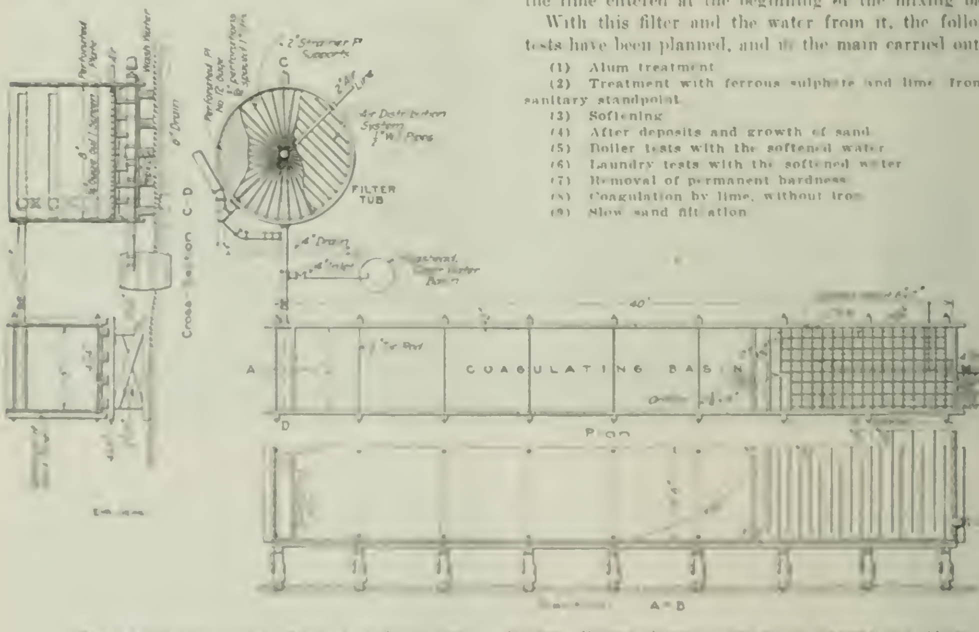
The Ohio spring floods of March-April, 1913, had such a bad effect upon the Cleveland water-supply as to lead the city authorities to adopt a general plan for water filtration. Accordingly, in May, 1913, Mayor Newton D. Baker appointed a Filtration Commission of five members, whose names are given at the close of this article, to study the situation and to make recommendations. It was decided at the outset that mechanical filters would be used but it seemed desirable to make a careful study of local conditions and to establish and operate a test plant before deciding on all the features of the new purification works.

The experimental or experiment plant, which was put in operation in July, 1913, consists of a coagulating tank and mechanical or rapid sand filter, shown by the accompanying line drawings. The intention was to operate the filter at the rate of 100,000 gal. a day but on account of the small size of the coagulating tank the filter has been operated at a 50,000-gal. rate. When the filter is worked at this rate, the detention period in the coagulating tank is $2\frac{1}{2}$ hours. The filter was equipped for using air preliminary to reversing the flow of water in washing, but the air wash was seldom used, as the pressure of the wash water, run from an elevated tank, was sufficient for ordinary purposes.

When the difficulties of manipulation had been overcome, this filter gave very good results, especially after the introduction of a very efficient mixing device. This consists of a series of baffles, through which the water moves for 30 minutes through a total distance of 1050 ft. Ordinarily, the iron was introduced at the pumps, while the lime entered at the beginning of the mixing baffles.

With this filter and the water from it, the following tests have been planned, and in the main carried out:

(1) Alum treatment
(2) Treatment with ferrous sulphate and lime from the sanitary standpoint
(3) Softening
(4) After deposits and growth of sand
(5) Boiler tests with the softened water
(6) Laundry tests with the softened water
(7) Removal of permanent hardness
(8) Coagulation by lime, without iron
(9) Slow sand filtration



Plan of Coagulating Basin and Mechanical Filter, Water-Testing Station, Cleveland, Ohio

(1) Alum Treatment—The turbidity and bacterial content of Lake Erie water vary, but the more important dissolved solids fluctuate very little. The alkalinity is about 90 to 95 p.p.m., with practically no extent of free carbon dioxide or of normal carbonate. There are in addition 16 p.p.m. of permanent hardness, mainly sulphate. With this alkalinity the water responds to alum treatment and the first trials were with this coagulant. The turbidity of the raw water during the period of trial was only 7. Beyond the removal of this turbidity and the study of the difficulties of manipu-

*Member of the Cleveland Filtration Commission; Professor of Chemistry, Western Reserve University, Cleveland, Ohio.

lation, this test had little value, as it was deemed advisable to change to lime and iron before good results were obtained.

(2) LIME AND IRON PRECIPITATION—This absorbed the chief interest on account of its relation to the possible softening of the water. After the difficulties of manipulation had been overcome and the final method of procedure adopted, the filter produced water which showed a turbidity of zero, and only once fermentation with lactose-bile in 10 c.c. This was during a period of six months, during which period 118 tests were made. The raw water showed considerable gas for 70% of the time. The special features which mark this long period of practically perfect results, were, aside from the general improvement in the handling of the plant, the large dosage of lime, and the diminution of the rate of filtration from 130,000,000 gal. per acre daily to 70,000,000, and finally to about 50,000,000. This lower rate was adopted in order to attain the desired time, 2.5 hr., in the coagulating basin. And this rate is the one which corresponds, with few exceptions, to the results reported in this article. For part of the time, during which only 2 to 3 grains of lime per gal. were used, with 0.5 grain of iron, the effluent was good. But the question of softening was kept so definitely in view that the dosage of lime was early adjusted to this end, and the sanitary efficiency worked out on this basis. The dosage finally settled on was: lime, 4.3 grains per gal.; iron, 0.5 grain per gal. The mean rate of filtration at this dosage was 51,500,000 gal. per day.

The data for the period of successful operation are as follows: Time, Nov. 8, 1913, to May 1, 1914, or 6 mo.; Number of tests, 118.

	Raw water	Filtered water
Mean turbidity	47	0
Mean bacterial count (agar)	46	3
Fermentation, per cent. of days	70	1

In the early stages of the operations some trouble was experienced by high counts, due to bacterial growth in the filter bed. This was remedied by occasional introduction of small amounts of bleaching powder into the wash water.

The main purpose of the filter was established by this series of tests, namely, the certain production, for a long period of time and during varying conditions of season and state of the raw water, of an effluent free from turbidity and also from coli (as shown by presumptive tests).

(3) SOFTENING—As soon as it was clear that satisfactory sanitary results were obtainable by lime and iron treatment, the emphasis of the tests was laid upon the softening. The reason which prompted these experiments was that it seemed desirable to obtain for the city the best water in every respect. Although the raw water is not extremely hard, it is hard enough to warrant its softening if this can be accomplished easily. The cost of softening will be more than repaid in the saving of soap, and the added comfort in home and laundry will be clear gain. There are industries in which the use of soft water would be advantageous, and in some boiler practice, at least, the improvement may be noteworthy.

An analysis of the water is given below. The amount of lime required may conveniently be measured by the total carbon dioxide in the form of acid carbonate, plus the magnesium present as carbonate. This will remove the excess carbon dioxide which holds the calcium and magnesium in solution as acid salts, and changes the magnesium carbonate into the less soluble hydroxide. More lime converts the sulphate and chloride of magnesium into hydroxide also. These changes are shown by the equations:

1. $CaH_2(CO_3)_2 + Ca(OH)_2 = 2CaCO_3 + 2H_2O.$
   $MgH_2(CO_3)_2 + Ca(OH)_2 = MgCO_3 + CaCO_3 + 2H_2O.$
2. $MgCO_3 + Ca(HO)_2 = Mg(OH)_2 + CaCO_3.$
   $MgSO_4 + Ca(OH)_2 = Mg(OH)_2 + CaSO_4.$
   $MgCl_2 + Ca(OH)_2 = Mg(OH)_2 + CaCl_2.$

The calcium carbonate and magnesium hydroxide are usually assumed to be insoluble, but where results are considered exactly, their solubility is not to be neglected, and, in the water treated as above, the hardness left in the water on their account is about 35 p.p.m. In addition, the soluble sulphates and chlorides are not converted to an insoluble form, and this hardness is unchanged. The amount of lime required for softening is: for half-bound CO_2, measured as $CaCO_3$, 95 p.p.m.; for $MgCO_3$, in addition, 13 p.p.m.; total, 108 p.p.m. Expressed as CaO this is 61 p.p.m. or 3.5 grains per gal.

Experience showed that the best results were obtained when enough lime was added to precipitate all the magnesium salts, namely, 21 p.p.m. as $CaCO_3$ or a total of 4.2 grains per gal. (73 p.p.m.) The amount applied varied from 4 to 5 grains, on account of imperfections in the feeding device, the average for the time under discussion being 4.35 grains. Due to this irregularity of feeding, the daily records for dosage and softening effect do not correspond, and the averages of the whole period need to be taken for a proper conclusion. These averages were: lime applied, 4.35 grain per gal.; iron, 0.50 grain. The average alkalinity for this period was 38; total hardness, 57. The average alkalinity to phenolphthalein for the period was 15. There were unusually high phenolphthalein alkalinities, for which the explanation was not evident; but in general, as long as the phenolphthalein alkalinity is not more than half the methyl orange alkalinity, it is true that there is no excess of lime present. The raw water had an average alkalinity of 88.5 and a hardness of 104.

Analyses of the raw and filtered waters, expressed as $CaCO_3$ p.p.m., with samples taken when the hardness was low, were as follows:

	Raw	Filtered
Calcium	82	29
Magnesium	34	24
Total hardness	116	53
Soap hardness	110	49
Alkalinity, methyl orange	95	35
Sulphate	14	18
Chloride, over alkali	2	2
Hardness by this test	111	55
Total solids	139	74

There have been a few results even more favorable than this typical one, but they could not be consistently obtained. The long series of experiments, both bottle and by means of the filter, indicated that we had here the best conditions. Less lime means incomplete precipitation; more lime means free calcium hydroxide and more hardness.

It is evident from the many series of bottle tests and from the long-continued filter test, that the Cleveland water is easily softened to the extent of about 50%. The residual hardness consists of the original permanent hardness, 16 parts; of hardness added by the ferrous sulphate, 3 parts; and of the hardness due to the solubility of the so called insoluble calcium carbonate and mag-

nesium hydroxide. This last item seems to be somewhat variable, at least under the conditions offered by the test filter, and a study of the data fails to reveal the causes of the variations. The evident means of control are proper dosage, thorough mixing and agitation, and finally filtration through sand. Aside from these variations, within narrow limits, no difficulties of permanent importance developed. The water was absolutely attractive in appearance and flavor, and sought after for drinking purposes by such as had the opportunity.

The time covered fall, winter and spring, with a range of temperature of the water from 61° to 33°. The effect of this change of temperature was not apparent.

The amount of wash water used at the beginning was high, 5 to 6%. With increased skill, use of baffles, lowering the rate of operation, and with bleaching powder in the wash water, it was reduced to about 1.5%. At the rate of 150 m.g.d., the time between washings was only 4 to 6 hours. When the rate dropped, the time increased correspondingly. Later, however, when the rate was 50 m.g.d., the time was increased in much greater proportion, namely, to about 40 hours.

(4) AFTER DEPOSITS AND GROWTH OF SAND—So far, no objection or obstacle has developed which threatens to interfere seriously with the plans for softening as just outlined. The effluent will be saturated or even supersaturated with carbonates of calcium and magnesium and magnesium hydroxide. Which of these are present, and whether the substances are present as supersaturated solutions or in colloidal condition, or whether the reaction is retarded, are questions difficult to answer. The quickest and most practical solution of the problem is an empirical one. That is, if there are no serious deposits, the matter may be passed over. If there are serious deposits, they must be prevented by the addition of carbon dioxide or by regulation of the dosage, with consequent lessening of the softening effect.

With abundant access of air, the absorption of carbon dioxide might be sufficient to eliminate the danger. But it is unlikely that absorption of that gas will be of any importance in the short passage from the filter to the mains. Artificial addition of carbon dioxide may be considered within the bounds of possibility, but for the present this may be left out of account. The thorough mixing by the baffles, followed by four hours settling and by filtration through sand, may solve the problem. What experience we may refer to in St. Louis, New Orleans and Columbus has been reassuring. At the test filter no deposits have come to the attention of the operator. Plates left in the water at the outflow showed traces of calcium carbonate after several months. Three litres of water standing in large flasks for six months deposited a total of [illegible] gram of calcium oxide and 0.0001 gram of magnesium oxide. A piece of porcelain having an area of 80 sq.cm., including both sides, was left in the water two months, after which 0.0012 gram of calcium oxide were found to be deposited on it. On the other hand, as already stated, there has been no evidence of deposit in any way ordinarily noticeable.

The sand is found to grow [by accretion] and its renewal must be considered as a part of the regular plan. A specimen of the sand from the filter, after being in use 10 months, was found to lose 7.4% of its weight when treated with dilute hydrochloric acid; another specimen, after 11 months, lost 17.5%. The composition of this incrustation was determined and found to be as follows: Fe_2O_3, 3.6%; $CaCO_3$, 90.7%; $MgCO_3$, 3.6%. Sand from the lower layers showed less incrustation, namely, about 7%, with the same chemical composition as that shown above.

In the upper layers of the filter considerable amounts of the sludge collected in soft masses, which penetrated to a depth of 6 to 8 in. and were not removed by the routine washing. The sand could be cleaned completely when removed from the filter and washed with some agitation. The composition of this sludge is: matter insoluble in HCl, 4%; Fe_2O_3, 3.0; $CaCO_3$, 87.15; $MgCO_3$, 4.03%. If this is reduced to the composition of the soluble matter only, we have: Fe_2O_3, 3.1%; $CaCO_3$, 90.8%; $MgCO_3$, 4.2%. That is, nearly the same composition as the incrustation on the sand.

Although the sand growth introduces complications, there may be some compensations in connection with it. The growth represents a diminution in the hardness of the water, and, what is more important, probably removes that portion of the dissolved substances which might afterwards settle out in the pipes. With respect to this precipitating effect of the sand, the record of a series of six bottle experiments and nine test-filter experiments will be of interest. In these the water was softened with lime, iron also being used, and soda added to remove the permanent hardness. Part of this water was filtered through paper, and part through sand, with the following results:

	Methyl orange alkalinity	Hardness soap
Bottle experiments		
Sand	37	36
Paper	43	43
Test filter experiments		
Sand	38	53
Paper	44	58

(5) BOILER TESTS—Two tests of the filtered and softened water have been made in the boilers of the pumping station. The softening of the whole city supply for the sake of boiler practice has not been suggested. If, however, a gain in this respect could be shown, it would give increased impetus to the interest in softening for domestic reasons. The records of two tests are as follows:

(1) 43 days. Water used, about 9,[illegible] lb.
Raw water using soda as boiler compound: Flue scale, 121 lb. Total scale and mud, 193 lb.
Filtered water: Flue scale, 42 lb. Total scale and mud, 64 lb.

(2) 30 days. Water used, about 6,[illegible] lb.
Raw water: As first test. Flue scale, 14 lb. Total scale and mud, 83 lb.
Filtered water: Flue scale, 12.5 lb. Total scale and mud, 39 lb.

Even if improved efficiency in the use of the boilers cannot be demonstrated, the difference in amount of scale is very large. The scale from the softened water, as is to be expected, contains larger proportions of calcium sulphate and of magnesium, and is noticeably firmer but not enough so to make any difference in the use of the cleaning machines.

(6) LAUNDRY TESTS WITH THE SOFTENED WATER—Two tests were made. The first at a city institution where only towels were laundered. The saving of soap, measured somewhat crudely, was about 25%, or even more, and the work seemed to the operator to be better done. The second test was carried out at a large commercial laundry, under the personal supervision of the superintendent. His estimate of the saving of soap and supplies was 65%. No marked difference in the quality of the work was apparent.

The question of the amount of soap saved by the

use of softened water is a difficult one to answer, as estimate forms such an important factor in every calculation. For the present purpose, it will be enough if it can be shown that the cost of softening is covered by the saving of soap. Until more exact knowledge is obtained, Whipple's estimate that at least 1 gal. of water is softened for every 100 gal. of water used, may be considered sufficiently conservative. Further using his formula ("Value of Pure Water," p. 27), the saving of soap at 5c. per lb. amounts to $360 for 60,000,000 gal. of water softened from 115 to 55. On the more conservative basis of the chemical equivalent between the calcium and the soap, the saving would be $125, which is about equivalent to the total cost for coagulants, and if at all correct, must be safely above the cost incurred for the softening only.

(7) Removal of Permanent Hardness—This amounts to 16 p.p.m. in the raw water, and is increased to about 19 parts by the added sulphate. Bottle experiments indicate that soda will remove this completely, when added in theoretical amounts, well agitated with the lime and subsequently filtered through sand. The mean result of six experiments thus conducted, with somewhat varying minor conditions, was: alkalinity to methyl orange, 37; soap hardness, 36. Consistent results better than this average could probably be obtained. This would give a very satisfactory softening. The first experiments made with the test filter have not been equally satisfactory, due perhaps to inadequate agitation. But even if the later tests confirm this result, it is hardly likely that this further softening will be adopted for the permanent filter, as the cost will be too great. The 1.2 grain soda required, amounting to 5 tons a day, would cost $100 for 60,000,000 gal. This would be for a reduction of only 19 parts, and is possibly in excess of the advantages obtained, especially when the handling of another chemical and all it involves is considered. Yet according to Whipple's calculation, even this would be paid for by the soap saved. A reduction of the hardness to 30% sounds attractive.

Coagulation by Lime, without Iron—The test was run for five days, with no modifications besides the omission of the iron. At the end of this time, the filter was required for other work. The inefficiency of the coagulation from the bacteriological standpoint was soon demonstrated. The second day there was a trace of gas; the third, 30%; the fourth, 35%; the fifth, 50%, each in 10 c.c. The turbidity during these same days was 0.0, trace, 2.5. The unfavorable impression was confirmed by the results from bottle experiments dealing with the sedimentation in the tank.

(9) Slow Sand Filtration—A slow sand filter was operated for several months until the freezing weather interfered. The filtration was efficient from the standpoint of turbidity. The bacterial results were not uniform. A number of periods of satisfactory results were obtained, from which it might be inferred that after all the manipulative difficulties had been overcome, the filter would operate satisfactorily. As, however, all considerations had led to the adoption of the rapid type, no further tests seemed necessary.

The writer must disclaim credit for a very considerable portion of the investigations recorded above. The test filter was operated under the general direction of the Filtration Commission of Cleveland, with the coöperation of the Water Department. H. B. Hommon, G. E. Flower, and G. D. Makepeace have been in direct charge of the test filter. The members of the Filtration Commission are as follows: President, A. W. Smith, Professor of Chemistry, Case School of Applied Science; Secretary and Consulting Engineer, R. Winthrop Pratt; Dr. Wm. T. Miller, member State Board of Health; Hippolyte Gruener, Professor of Chemistry, Western Reserve University; and Dr. R. G. Perkins, City Bacteriologist and Professor of Hygiene and Preventive Medicine, Western Reserve Medical School.

Ohio Experience in the Use of Road Oils*

Poor results in the use of oil treatments frequently come from the fact that the surface had not been previously cleaned in a proper manner. If possible, the surface should be swept with horse sweepers, and afterward with hand brooms, so as to remove the dust from between the stones to a depth of from 1/4 to 3/4 in. The heavier the grade of oil used, the more important it is to have a clean surface on which to apply it. The surface should be dry and the warmer the air temperature the better.

There has been considerable discussion during the past year concerning sprinkling of the stone with water before applying the bitumens, it being claimed by some that better results are secured. While during a dry, dusty time, better results may be obtained by first lightly sprinkling the stone with water before applying the bitumen, this information is likely to be misleading; for it is believed that it is not the presence of water that might cause the better results, but the effect the water has in cleaning the dust which gives a better adhesion of the oil.

Hence, we would conclude that if sprinkling with water before applying the oil is done, it should be only on hot, dry days, and then sufficient time given after the sprinkling for the water to practically all evaporate before the oil is applied. Therefore we are still warranted in saying that bitumens should be applied only to dry, warm surfaces. During June, July and August is the best time of the year to apply such materials to the road.

The amount of oil that should be applied to the road at any one time will depend upon the condition of the road surface, the quality of the oil used, and the nature of the traffic. In general, it may be said that a couple of light applications during the year will give better results than a single heavy application of the same amount of oil. For the lighter oils, on a comparatively smooth surface, an application of not to exceed 1/8 gal. per sq.yd. may be all that should be applied at one time, while on a rough, pitted surface (with the binder swept from the top surface of the road to a depth of from 1/4 to 3/4 in.) as much as 3/4 gal. per sq.yd. of the heavier oils might give more satisfactory results.

The aim should be to put on just sufficient oil (and screenings) to form a thin mat over the surface of the road. This mat should not be of any appreciable depth over the surface of the larger stones, but sufficient to well seal up the voids between them. This will hold the binder in the stones and make the road surface water-tight.

A medium heavy cold oil will cost from 4½ to 6c. per gal., delivered in tank cars. The cost of applying the cold oil varies from ½ to 1c. per gal., while the cost of applying the hot oil will vary from 1½ to 3c. per gal.

*From Bulletin No. 27, Ohio State Highway Department, June, 1914.

The Design and Construction of the Bassano Dam--Part II

By H. B. Muckleston*

As stated in my previous article [Eng. News, Aug. 27, 1914, p. 425] the Bassano Dam is located on the Bow River, and is a part of the immense irrigation system of the Canadian Pacific Railway which extends from near Calgary, Alberta, many miles to the eastward. The dam is a composite structure, consisting of a long earth embankment and an Ambursen reinforced-concrete spillway section, provided with Stoney gates, flanked on one side by reinforced-concrete head gates, also provided with Stoney gates.

Layout of Plant

Construction was commenced in October, 1910, with the erection of the plant and building of Coffer-dam No. 1. Fig. 1 shows the general layout of the construction plant. Three cableways with spans of 975 ft. were erected, requiring tail towers 95 to 85 ft. in height on the west shore, and head towers from 47 to 55 ft. high on the east shore. The two upstream cableways, which were used for handling forms and concrete, each had a carrying capacity of three tons, whereas the downstream cableway, used extensively for gravel, had a capacity of five tons.

Gravel—A gravel pit, located about 500 ft. west of the west abutment and on the upstream side of the earth dam, was opened up, requiring about 16 ft. of stripping. The gravel was found to be naturally well graded, fairly clean, and containing about 30% excess of sand. The stripping and excavation was done with a [illegible] bucket mounted on a traveling [illegible] car. The stripping was [illegible] done during the night, and in the daytime the gravel was excavated and loaded in dump wagons or a [illegible] under the gravel cable. From here it was [illegible] which was picked up by the cableway and carried to the [illegible] of the [illegible] plant. Two [illegible] gravel pipes, with [illegible] controlling gates, conveyed the gravel from the bin to two measuring hoppers located above the two 1-yd. Smith mixers (Fig. 2).

Cement and Concrete Handling—The cement, which was stored in a cement shed with a capacity of 800 bbl., was by means of an overhead conveyor carried to a hopper whence it was shot down through a 12-in. pipe into a bin placed between the two mixers. The bin was equipped with two spouts in which were fixed measuring slides for the different mixtures, and the cement was in this way distributed to the measuring hoppers which contained the gravel. The whole of the dry mixture was then by a tripping device dumped into the mixers. The two upstream cableways, located directly above the mixers, picked up the concrete buckets, which were of the controllable bottom-dump type, and carried them to wherever concreting was under way. Here the concrete was transferred to a controllable bottom-dump car, which traveled on sectional track resting on the forms. The maximum output of this concreting plant was 350 cu. yd. per 10-hr. day.

Owing to the considerable size of the construction plant, well appointed repair shops were installed so that delays might be avoided and repairs and general maintenance carried out in an efficient manner.

The size of crew engaged varied considerably from time to time, the maximum number being about 750. The unskilled labor was principally Italian, the skilled labor being of all nationalities. Suitable bunk houses and dining rooms for each class, electrically lighted and steam heated, were built, and a waterworks and sewerage system installed. As the river water was contaminated to some extent, especially during the summer, all water for drinking and cooking was [illegible].

All plant and construction materials were shipped to Bassano, a railway station about four miles from the dam, from which point the hauling was done partly by teams and partly by traction engines.

As the high-water period generally commences about the middle of May and lasts well into August, it was necessary to have each section so far advanced in construction before that time that work could be continued even if the cofferdams were flooded. The general con-

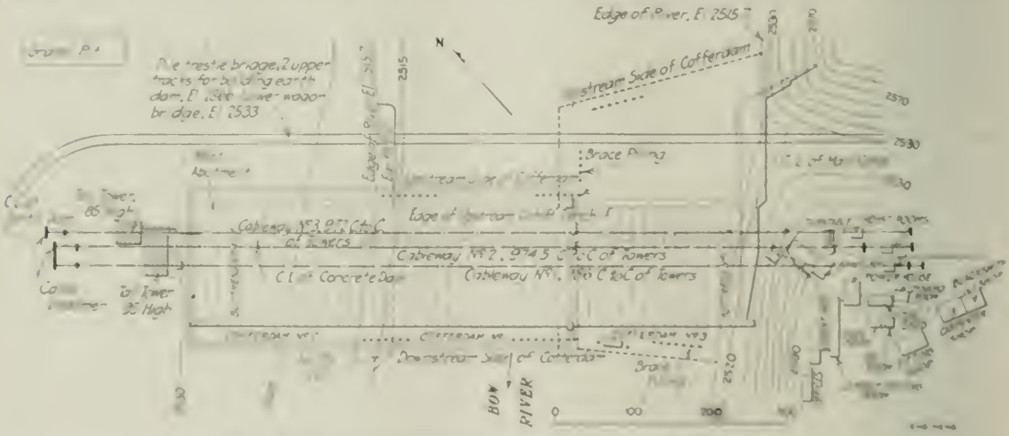


Fig. 1. General Layout of Construction Plant for Bassano Dam

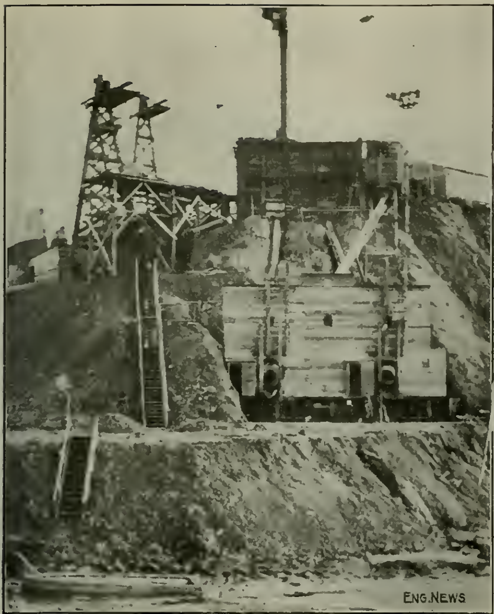

FIG. 2. GRAVEL BIN AT BASSANO DAM, WITH GATE-CONTROLLED PIPES LEADING TO MEASURING HOPPERS OVER CONCRETE MIXERS

struction program was therefore arranged accordingly.

COFFER-DAMS—The first coffer-dam constructed took in the central third of the structure, and the river was passed through the easterly third. Upon completion of the central third to a level above high water, the coffer-dam was removed and the river passed through between the buttresses. The westerly third was then started, upon completion of which the easterly third was commenced, with the river passing through the central and westerly section, the design of the type of structure lending itself admirably to such a procedure (see Fig. 3). The coffer-dams consisted of two rows of piles 12 ft. apart, the piles in each row being 8 ft. c. to c. The outside row carried walings supporting 3-in. tongued-and-grooved sheet piling, which was driven with a steam hammer, the back row acting as brace piling. As the river is fairly shallow at the dam site, the greatest depth at low water being only 8 ft., no particular trouble was experienced in the construction of the coffer-dams.

FORMS—All forms used were sectional. Fig. 4 shows their general arrangement, which has been described in various articles on similar dams in the ENGINEERING NEWS. One departure from general practice, however, was that of removing one entire group of forms together by means of the cableways and reërecting them without taking them apart. This process is shown by Fig. 5, where a whole set of forms for the side of one of the buttresses is being removed for reërection elsewhere.

EXCAVATION—Most of the excavating was done by teams, wagons and slip scrapers. As the work was continued all the year round, special arrangements had to be made for thawing out the ground. At the end of the day tarpaulins 100x150 ft. were supported by means of horses over the excavation and numerous salamanders placed underneath and kept stoked overnight. In the morning the canvas and the salamanders were removed and work continued. In this way it was possible to gradually thaw the frost out of the ground, although in places it was frozen 6 ft. deep.

PROGRESS—Concrete was first poured in Floor Bay No. 17 on Mar. 22, 1911, and continued without interruption practically until November, 1912, when the bulk of the concrete had been placed.

During the time no stops were made except when the

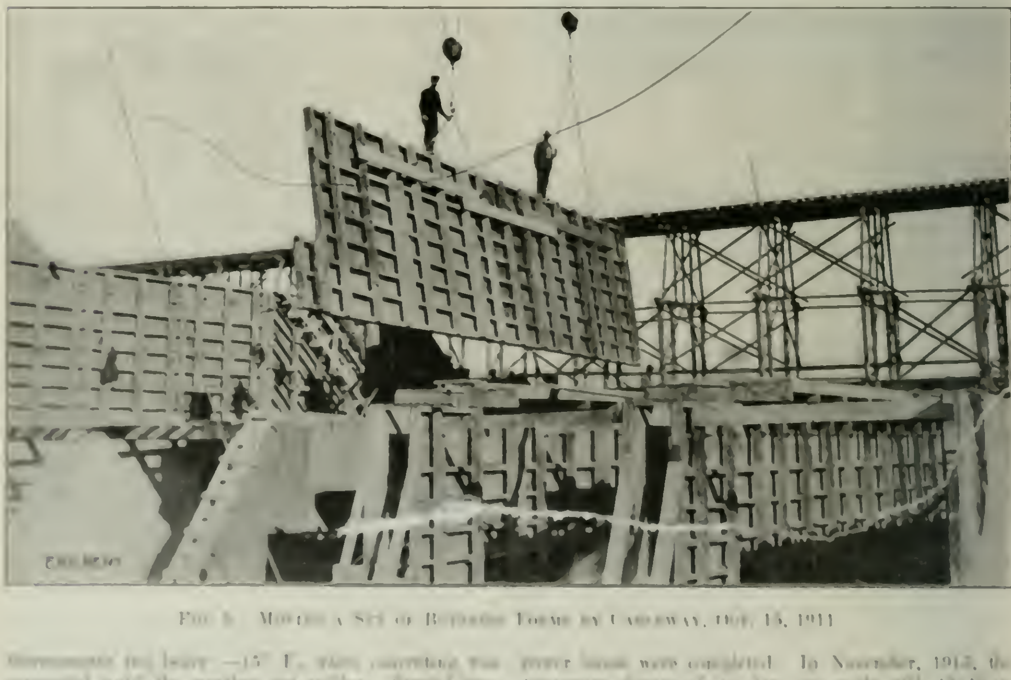

FIG. 5. MOVING A SET OF BUTTRESS FORMS BY CABLEWAY, OCT. 15, 1911

thermometer [illegible] —15° F., when concreting was suspended until the weather got milder. Special provisions were made where the plant was located for heating the water and gravel, and as all the forms were double-boarded no difficulty was experienced in keeping the concrete from freezing. In fact, it was noted on many occasions that the concrete would still be steaming hot when the forms were removed about four days after the concrete was placed. Construction was resumed in April, 1913, and completed in May, 1914, during which period the spillway walls and the piers over the headgates and power house were completed. In November, 1913, the temporary closure of the dam was made with 12x12-in. stop logs, as shown in one of the details in Fig. 3, followed immediately with the permanent concrete closures, the driving of the piling under the lower part of the ogee curve and the concreting of same.

The piles, which were 12x12-in. square timbers shod with cast-iron points, were driven to an average depth of 25 ft., with two 1½-ton steam hammers, in inclined leads. This work was done inside a coffer dam built on the concrete carpet and the river taken care of by means

of the two 6-ft. under sluices in the middle of the structure (Fig. 6). The gravel fill inside the dam was pulled by trains running on the bridge deck and loaded by a steam shovel located at a gravel pit at the west end of the earth dam. The gravel was dumped into hoppers and conveyed to the interior of the dam by means of spouts passing through holes cut in the crest.

Sluices—The Stoney sluices and all their machinery for both the dam and the headworks were manufactured by Ransomes & Rapier, Ltd., of London, England. They are of the usual type, working on free rollers and stanched by a rubber-covered round rod hung in the angle between the pier and the skin of the gate. Each sluice is provided with means for hoisting by hand. Power operation for the crest sluices is provided for by four movable trolleys on the bridge, arranged to engage any one of the operating shafts. In the case of the canal head sluices a separate motor is provided for each gate. In order to prevent any possible damage from over-winding, each gate is equipped with a limit switch which breaks all electrical connections when the gates approach within 3 in. of the full travel at either end.

The design for the gates and operating mechanism was worked up by the manufacturers under specifications drawn up by the engineers of the Railway Company. The gate, guides and machinery were shipped in the knockdown, and erected by the Railway Company under the supervision of an expert erector sent out from England. So well had the work of manufacture been done that the various parts went together with little or no subsequent alterations or fitting

Auxiliary Gate—As an emergency closure in case of accident to the main crest sluices, a special auxiliary gate is provided. This gate is similar to the permanent gates except that the position in the guides is reversed so that the skin is on the downstream face of the girders instead of the upstream face, and that an endless chain of live rollers working on the gate is provided instead of the rigid roller trains provided for the main sluices.

The auxiliary gate is handled by a gantry crane running on rails on the bridge girders. As the gate will be used but seldom, no provision is made for counterweights or power operation.

Power Plant—As stated above, the time factor in flood rises is so small that special provision was necessary to insure very rapid operation of the crest and canal sluices. To provide electric power for this work, a small power plant was built in a chamber provided for the purpose in the east abutment. The plant consists of a 180-hp. reaction turbine, with Woodward governor, connected by belt to a 100-kv.-a., three-phase, 60-cycle, 2400-volt generator. The plant is equipped with step-down transformers furnishing current at 110-220 volts for the operation of the motors and for a complete lighting system in the dam and about the headworks.

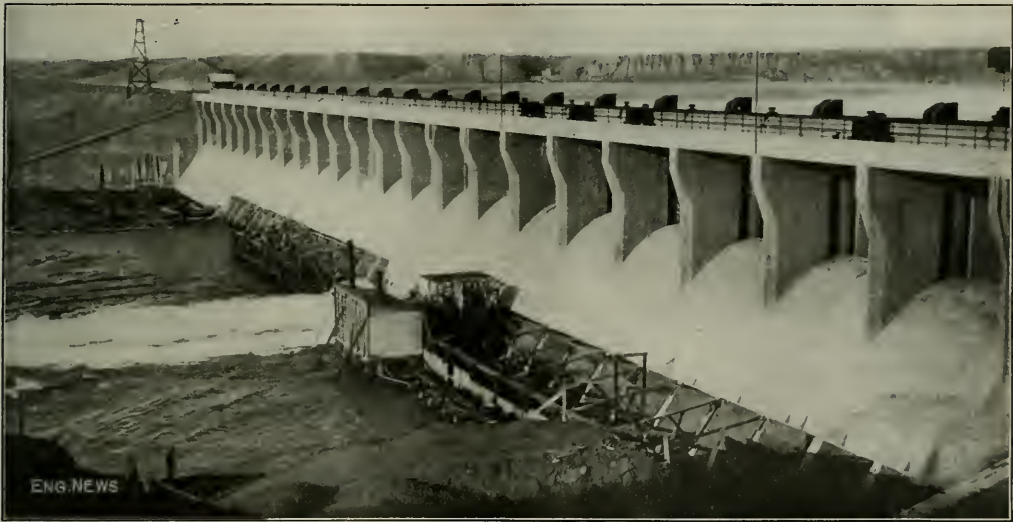

Fig. 6. Making the Permanent Concrete Closure of the Bassano Dam; Nov. 30, 1913
(The river flow is being passed through two 6-ft. under sluices.)

A view of the finished dam, looking along the top from the head-gates end, is shown by Fig. 7.

Earth Embankment—The earth embankment (Fig. 8) was built of selected material from the canal cut. The specifications provided for the most approved methods of construction by spreading and rolling the materials in thin layers and for sprinkling if found necessary. The rear half of the dam is underdrained in order to steepen the plane of saturation, and to intercept any possible flow along the surface between the dam proper and its foundations. Before commencing construction, the foundation surface was carefully stripped of surface soil and thoroughly plowed to give a good bond.

The contractor for the earth portion commenced work by building a double-track narrow-gage trestle across the river. On the right bank, this trestle was continued as two single-track trestles about 100 ft. apart. The material was loaded into dump cars and hauled by locomotive to the dam, where it was dumped from the tres-

FIG. 7. LOOKING WEST ALONG THE TOP OF THE BASSANO DAM

tles and spread by four-horse Fresno scrapers. The continual trampling by four horses abreast, and the thin spreading which this method resulted in, gave such a thoroughly dense bank that the clause of the specifications relating to rolling was not exacted.

At the connections with the spillway the earth was very carefully spread and compacted. A good proportion

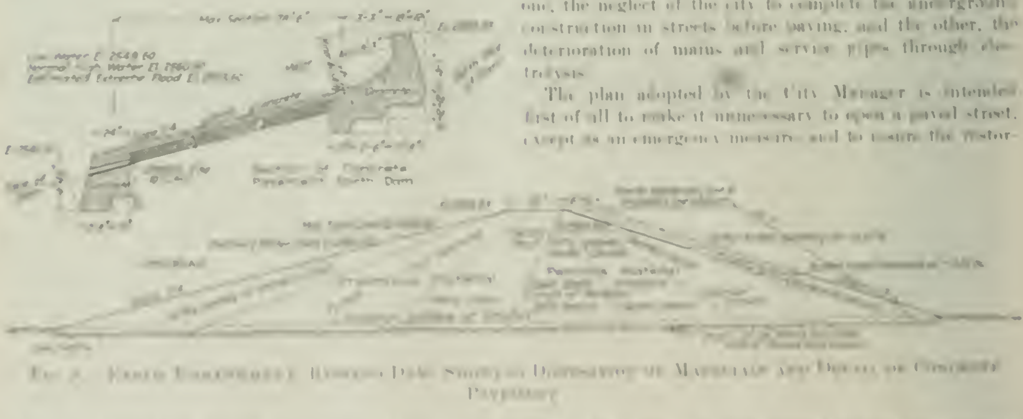

FIG. 8. EARTH EMBANKMENT, BASSANO DAM, SHOWING DISPOSITION OF MATERIALS AND DETAIL OF CONCRETE PAVEMENT

of this work was done by flushing the material by means of a jet of water under pressure. The material available was not very well suited to the process, being an unusually pure blue clay, and the result has not been entirely satisfactory, owing to the very long time required for the bank to drain.

CONTRACTORS—The preliminary designs for the dam and the surveys for the project of which it is such an important part were made by the [illegible]. The detailed designs for the spillway and headgates were made by the Ambursen Hydraulic Construction Co.

H. Siebens was resident engineer for construction of the concrete work, and has assisted in the preparation of this article. A. J. Raymond was Superintendent of Construction. A. Fromm-fer, Division Engineer, was in charge of construction of the earth embankment and paving, and the excavation of the canal.

The work as a whole was under the direction of A. S. Dawson, Chief Engineer of the Department of Natural Resources, Canadian Pacific Railway Co., Calgary, Alberta.

Regulation of the Opening and Restoration of Pavement Surfaces in Springfield, Ohio

By GEORGE L. BINKLEY*

Since the first of the present year, when the city of Springfield, Ohio, installed the commission-manager plan of government, much attention has been given by the city officials to the problem of street maintenance. One of the first steps of City Manager Charles E. Ashburner was the adoption of an economical and efficient system of street repairing.

Early in January, an investigation was conducted into the history of street repairing, as shown in the records of the city during the year 1913, and it was found that permits had been issued for nearly 800 trenches in improved streets, in addition to the openings made by public-service corporations. An examination of the streets, as well as the methods of backfilling and repaving, showed that practically every trench made during the preceding year was a potential chuck hole. The investigation showed the need for trench work to be due chiefly to two causes: one, the neglect of the city to complete the underground construction in streets before paving, and the other, the deterioration of mains and service pipes through electrolysis.

The plan adopted by the City Manager is intended first of all to make it unnecessary to open a paved street, except as an emergency measure, and to insure the restoration of the surface as satisfactorily as good workmanship makes possible. The assistance of the Bureau of Standards at Washington was secured in an effort to reduce the deterioration of underground metallic construction, and the public-service corporations operating electric-railway lines in and through the city have readily agreed to cooperate in the general plans of electrolysis mitigation.

*[illegible], Springfield, Ohio.

Laws for the Preservation of Pavements

The present charter of the city of Springfield provides that after the paving of a street, no excavations can be made within a period of five years from the date of the completion of the work, excepting by permission of the city commission, in which four-fifths of the members concur. Following up the opportunity thus opened, it was decided to include in all resolutions of necessity, which constitute the first legislative step in street-paving procedure, a notice to the owners of property fronting upon the street to the effect that all sewer, water, gas and other connections must be installed previous to the commencement of the pavement-construction work: and that in the event of the failure of any property owner to comply with that notification, the city reserves the right to construct such connections, and assesses the cost against the property to be benefited.

Furthermore, it was decided that the paving of a street should not take place until every other form of improvement in the street had been provided. Previously, macadam streets had been torn up in a number of instances for the construction of sewers, and brick- and sheet-asphalt streets were trenched for considerable distances to install telephone, telegraph and electrical conduits. The new method of procedure calls for a study of the probable needs of a street in the way of underground construction during the life of the street paving, and the making of ample provision for the needs before the paving work starts.

Restoration of Pavement

It was recognized, however, that these precautionary measures would not entirely eliminate the necessity for opening paved streets, and that the policy of street maintenance would not be complete without some provision being made to insure the restoration of the street surface, where trenches were made.

Cash Deposits—The city consequently decided to assume all responsibility for the repair of trenches in the future. An ordinance was passed, repealing the legislation previously in force, which had required persons opening paved streets to give bond for the satisfactory repair of the paving, and substituting therefore a provision for the issuance of permits for street openings only when deposits are made to cover the cost of the trench repair.

Permits—Plumbers and all others desiring to dig trenches in streets are required first of all to file an application in the office of the city engineer, upon a form furnished by the city for that purpose, stating the name of the applicant, the location and purpose of the opening, the length and depth of the trench, and the names of all persons interested, or to be benefited by, the work to be done.

The city engineer is required to prepare and to keep on file a schedule of the estimated cost of backfilling and resurfacing in various kinds of street paving, and from this schedule the amount of the deposit required is determined. The permit issued to the applicant contains all the information upon the application, together with a statement of the amount of the cash deposit, and the dates between which the opening may be made. The permits are numbered serially, and a daily report is made to the city auditor, showing the amount deposited for each permit, while the cash deposits are turned over to the city treasurer each day, and placed in what is known as the Special Repair fund.

Inspection of Underground Work—A carbon copy of the permit is turned over to a plumbing inspector who passes upon the quality of the work installed before the trench is backfilled. After having completed his work, the holder of the permit notifies the engineering department of that fact in writing, and after it has been ascertained that the plumbing inspector has approved the work so far as it has been completed, a postcard is mailed to the holder of the permit, notifying him that at 7 a.m. of a given day the city will assume responsibility for the trench. Until that time, the person or company holding the permit is responsible for barricades and red lights on the trenches.

Pavement Repairs—In backfilling the trench, the earth is firmly tamped, the street paving removed for a foot or so back from the edge of the trench and a new concrete foundation laid with its edges upon firm earth which has not been disturbed. The wearing surface is then added, and the work finally passed upon by an engineer.

The street-repair foreman makes a report to the chief engineer upon the cost of backfilling and resurfacing each trench, giving the expense for labor and material. This report is certified to the city auditor, who issues a warrant to the treasurer for a refund of any balance left in each deposit, or collects from the holder of the permit any amount in excess of his deposit, should the expense of backfilling be greater than the estimate. Should the holder of a permit fail to pay an excess charge, he would be refused any further permits.

Charges for Pavement Repairs—In the schedule showing the estimated cost of backfilling and resurfacing trenches, three classifications are made, according to the depths of trenches. The first classification includes all trenches of 30 in. or less in width, and 4 ft. or less in depth. The second classification includes all trenches between 4 and 7 ft. in depth, and restricts their width to 30 in. The third classification permits of a 40-in. width, and a 12-in. depth.

The charge per lin.ft. of trench in the various kinds of street paving, in each classification, is shown by the accompanying table:

TABLE SHOWING CHARGES FOR BACKFILLING AND RESTORING PAVEMENT

Surface	First	Second	Third
Brick	$1.02	$1.20	$1.61
Sheet asphalt	1.34	1.52	1.74
Asphalt block	1.59	1.74	1.99
Asphaltic concrete	1.24	1.42	1.86
Medina stone	2.11	2.32	2.54
Granite	2.11	2.32	2.54
Wood Block	1.74	1.92	2.14
6-in. waterproof macadam (mixed)	0.71	0.92	1.32
6-in. waterproof macadam (penetration)	0.59	0.77	1.17
8-in. waterbound macadam	0.41	0.62	0.97
8-in. gravel	0.31	0.52	0.84

Special estimates are prepared for trenches not included in the general classification given above and charges made accordingly.

The plan appears to be satisfactory all around. The plumbers, some of whom at first objected, are now practically a unit in expressing their approval, as it relieves them of the necessity of keeping repair gangs. The public, previously dissatisfied with the condition of the streets, is at present waiting to see what the results of the new plan will be, but are not giving expression to any noticeable criticism.

Water-Supply of Boulder, Colo.

By Clare V. Mann*

Few cities in the world have a water-supply drawn from so high an elevation and so pure and abundant as Boulder. The elevation of the sources is from 2 to 2½ miles above sea level. The character and location of the drainage area insures a high degree of purity. The average consumption (and waste) is seldom below 200 gal. per capita per day and in the dry summer months often reaches 400 gal.

Boulder, the seat of the State University of Colorado, is a city of 10,000 inhabitants, situated 29 miles northwest of Denver, and at the extreme eastern base of the foothills of the Rocky Mountains. The elevation of Boulder above mean sea level is 5350 ft.

The water-supply of Boulder is derived from the Silver Lake drainage area, 8.73 sq.mi. in extent, varying in altitude from 10,200 to 13,500 ft. above sea level, and lying at the crest of the Continental Divide, 20 miles due west of Boulder. The annual precipitation over the entire watershed averages from 40 to 45 in., the major portion of which falls in the form of snow from September to May, inclusive. A small portion of this snow, lying on southern slopes, is melted as it falls, or in the course of a few days or weeks. The remainder is piled by the strong westerly winds into enormous drifts in the ravines and deep recesses of the watershed, there to remain until melted away in the warm and sunny days of June, July and August. One of the drifts which so accumulates has never melted entirely away. It is, in fact, a true glacier, one of the very few now existing in Colorado. It is situated near the top of Arapahoe Peak and is called the Arapahoe Glacier.

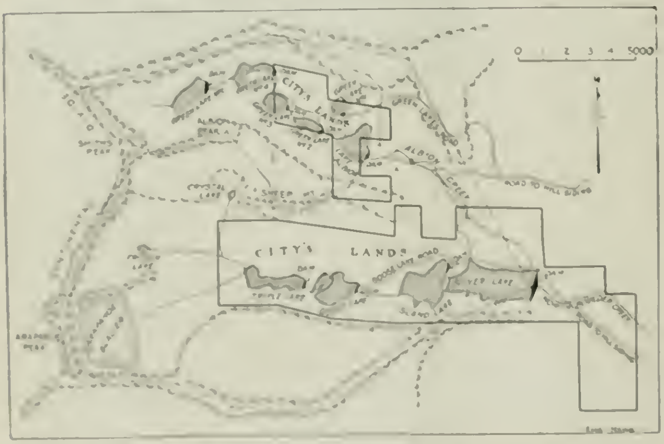

Fig. 1. Map of Water-Supply Drainage Area, Boulder, Colo.

The lesser portion of the annual precipitation falls as rain, hail or sleet during June, July and August, and serves to augment the melting of the snows. As an example of the monthly distribution of precipitation, the measurements found for 1911—a normal year—is given:

PRECIPITATION IN INCHES, SILVER LAKE WATERSHED, 1911

Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec	Total
5.85	6.20	7.60	7.90	1.70	1.20	4.[illegible]	2.12	2.70	2.50		1.65	43.66

The percentages of runoff and of loss from evaporation have not been determined.

In the Silver Lake Watershed, there rise the north and middle branches of North Boulder Creek, otherwise known as Albion Creek and Arapahoe Creek, respectively. The normal flow of Albion Creek varies from 1 sec.-ft. or less in December and January, to from 20 to 25 sec.-ft. in June, July and August. The flow of Arapahoe Creek varies from 1 to 4 sec.-ft. in December and January, up to as high as 60 and 100 sec.-ft. in June, July and August.

Along the headwaters of each of the two branches of North Boulder Creek there lie (Fig. 1), at short distances from each other, 10 natural lakes, of glacial formation. Viewed from the top of Arapahoe Peak, these lakes, with their crystal-clear water and their setting of wild and rugged mountain peaks and dense pine forests, form a bit of scenery which, once seen, can never be forgotten. Fig. 2 is a view of the chain of lakes on Arapahoe Creek. The names are as follows: Triple Lakes, Goose Lake, Island Lake, and Silver Lake.

In 1904, because of the pollution of the old source of supply—Middle Boulder Creek—with tailings and slimes from the mines and mills above the old Lower Intake, it became necessary for Boulder to seek a new source of supply above the region of possible pollution. The city purchased a number of the lakes in the Silver Lake Watershed, and acquired title, by special Act of Congress and otherwise, to a considerable portion of the lands within the watershed, and adjoining the lakes. Surveys were made at each dam site, and preliminary work was done in excavating outlet channels at each lake. The contemplated areas, capacities, and heights of the several reservoirs, together with the original estimates of the cost of development, were as follows:

Reservoir	Area, acres	Capacity, million gal.	Height dam, ft.	Cost
Triple Lakes	[illegible]	[illegible]	[illegible]	[illegible]
Goose Lake	[illegible]	[illegible]	[illegible]	[illegible]
Island Lake	[illegible]	[illegible]	[illegible]	[illegible]
Silver Lake	[illegible]	[illegible]	[illegible]	[illegible]
Albion Lake	[illegible]	[illegible]	[illegible]	[illegible]
Total		[illegible]*		[illegible]

*One thousand million gal.

At the present maximum rate of consumption, this amount of storage (one year's filling) would be sufficient to last the city for two years.

To eliminate waste and all possibility of pollution of the water enroute from the lakes to Boulder, a steel gravity pipe line was built in the summer of 1906. It is approximately 9 miles in length, and has its intake at the "Intake Reservoir," a point on North Boulder Creek, six miles below Silver Lake, at an elevation of 8900 ft. above sea level. This reservoir has a capacity of 9,300,000 gal. The lower end of the line discharges into the head-gate chamber of the old gravity pipe line in lower

*Boulder, Colo.

Boulder Cañon, situated on Middle Boulder Creek at a point approximately three miles west of Boulder, and 5950 ft. above sea level. The pipe line consists of 3800 ft. of 12-in., 16,800 ft. of 15-in. pipe and some 27,000 ft. of 18-in. pipe, all pipe ¼ in. thick, lap-welded longitudinally. Joints are made with cast-iron bells, which receive the ends of two consecutive pipes. The points are calked with oakum and lead in the usual manner.

From the old intake of the lower Boulder Cañon pipe lines, the water is conveyed to the city through several thousand feet of 24-in. wood-stave and 20-in. cast-iron pipe and through a separate 15-in. steel gravity line. Sunshine and Chautauqua reservoirs serve to equalize the pressure on their respective distributary systems, which are operated separately and also provide some protection in case of a serious fire, or break in the main supply-pipe lines. They have capacities, respectively, of 5,775,000 and 3,712,500 gal.

Since completing the Mountain Pipe Line, in 1906, the city has actively undertaken the development of its mountain reservoir system. In 1908, a timber crib dam 30 ft. in height, with loose rock fill, was completed at Goose Lake, at a total cost of $26,216. In June, 1910, active construction was begun on a 60-ft. cyclopean rubble-concrete dam at Lake Albion. This dam is now two-thirds complete, and to date has cost nearly $210,000. When complete, the dam will contain 17,315 cu.yd. of masonry.

In the summer of 1911, excavation was made at Silver Lake for the foundations of a rock-fill dam 35 ft. in height. A contract was subsequently let to the Peter O'Brian Construction Co., of Denver, for placing the rock fill, and otherwise completing the dam. Owing to a failure to find suitable foundations within from 15 to 25 ft. of the depth indicated on the contract drawings, Mr. O'Brian refused to execute his contract, and on Aug. 20, 1912, the work was abandoned. Since that time, no further real progress has been made on the dam, but the city has done some prospecting and other preliminary work which should have been done in the beginning. In all, about $30,000 have been spent on the dam to date. At this writing, new plans for a rock-fill structure are under consideration, and it is expected that work will shortly be commenced in accordance with them.

No plans of a definite character have so far been made for dams at Island and Triple lakes, and it is probable that none will be made in the near future. For additional storage, an effort is being made to gain possession of the five Green Lakes lying above Lake Albion.

FIG. 2. CHAIN OF LAKES ON ARAPAHOE CREEK; PART OF WATER-SUPPLY OF BOULDER, COLO.
(Beginning in the foreground the lakes shown are named as follows: Triple, Goose, Island, Silver.)

With the dams completed, which are contemplated or now under construction, and with the Mountain Pipe Line extended up North Boulder Creek to a point above the Denver, Boulder & Western Ry., the City of Boulder will have a water system of which it may well be proud, and which, in the semi-arid State of Colorado, will be worth at least $1,000,000.

The writer was Resident Engineer on the Albion Dam during the construction seasons of 1910, 1912 and 1913, and Inspecting Engineer on Silver Lake in the season of 1912.

Russian Thistles Caused Breaks in the Irrigation Canals of the Truckee-Carson Project in June, 1914, according to the United States "Reclamation Record" for July-August. The only information on the subject is:

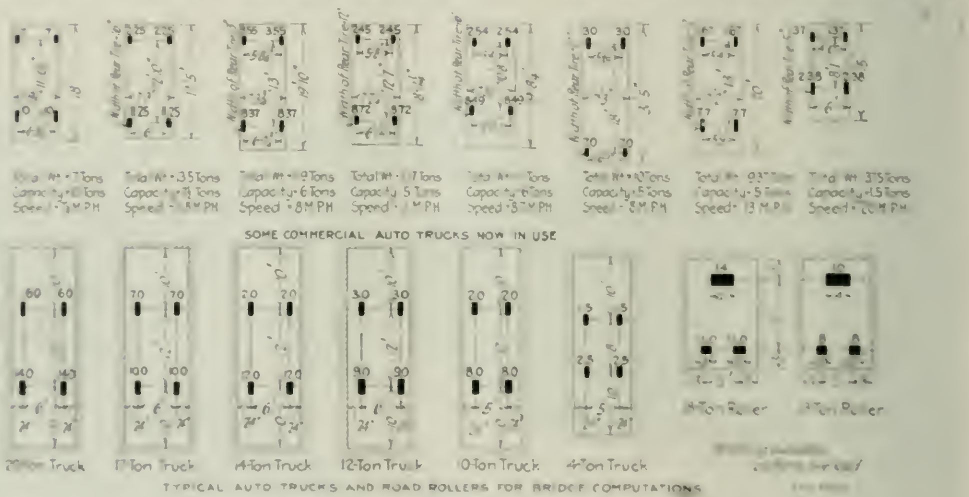
The accumulation of Russian thistles in the canals formed dams in the structures and caused many breaks in laterals which kept the repair force busy. This nuisance decreased towards the end of the month.

Motor-Truck Loading on Highway Bridges

By L. E. Mannheim* and R. W. Gastmeyer*

It is desired in the following article to call attention to the inadequacy of a large percentage of our highway bridges to accommodate the heavy automobile traffic of today. It appears to be a fact that automobile-truck designers are blindly turning out machines which neither ordinary highway bridges nor highway macadams will sustain.

Recently, there have been several published reports of failures of highway bridges. These failures are causing railroads and other corporations, as well as states and municipalities, owning highway bridges for whose strength they assume the responsibility, to take an active interest in the weights of auto trucks being placed upon the market. It is time that some one in authority call a halt to the excessive wheel loads our modern trucks are assuming, or at least that the state authorities inaugurate the practice of posting signs on all highway bridges limiting the loads permissible, and at the same time regulate the concentrations permitted on state highways.



Load Diagrams of Auto Trucks and Road Rollers

Old Loadings and Modern Loads

The customary loading assumed for the design of a highway bridge in the past has been a certain uniform live-load alone, possibly a typical heavy wagon or road-roller, or a uniform live-load with a concentration. These types of loading, of course, had their origin at a time when traffic conditions were readily taken care of by such assumed loads. But these *older types of loading* are inadequate for purposes of design to take care of modern conditions; they should be replaced by some types of typical motor trucks. Most auto trucks now give greater axle concentrations than any roller heretofore used, and with less favorable distribution.

Greater Velocity of Motor Trucks—The chance that two rollers might be on a bridge at the same time was so remote that it was never deemed practical or fair to design floor-beams for that loading. Today it is a common occurrence that *two motor trucks* pass each other on a bridge.

Modern trucks traveling at the rate of 12 mi. per hr. can be stopped within a comparatively short distance; this sets up *longitudinal stresses* in the floor system. Further, where the planking is not adequately tied down, the longitudinal forces may prove destructive to the floor surface.

Better *protection fences* must be given trusses to protect them against possibility of collision.

The trucks, traveling at a much greater speed than the rollers, produce *more jar and sway*, which require stiffer bracing.

Centrifugal forces will act on bridges occupying a sharp bend in the roadway, an effect which was negligible with slow-speed rollers.

Thus, many conditions arise which have heretofore never been encountered in simple highway-bridge design. What is more, trucks are frequent in their passage, while rollers come along quite infrequently, and as a result we have not merely occasional overload but a daily repetition of the overloading.

Comparative Figures on Trucks and Rollers

Accompanying this article is a diagram showing concentrations and wheel spacing, as well as outside dimensions of various trucks which are being sold today. From these examples certain typical trucks are recommended to be used for designing new bridges as well as for investigating old bridges. It should be noted that the area assumed as covered by the typical trucks is based on the idea that the truck is in motion; possibly more than 12 ft. in the direction of traffic would be justifiable, but the distance is at least a conservative one.

The table accompanying shows the comparison between trucks representing actual present-day operation and two common types of road rollers, 18 ton and 10 ton, and

*Engineering Department, New York Central R.R., Grand Central Terminal, New York City.

COMPARATIVE BRIDGE MOMENTS FROM ROLLERS AND AUTO TRUCKS

Maximum moments in thousand foot-pounds for a width of bridge equal to the width of roller or truck.
Impact is included as follows:

For rollers, 25%

For trucks and uniform load, $\frac{150}{L + 300}\%$ where L = loaded length in ft.

Trucks assumed to be surrounded by uniform live-load of 100 lb. per sq.ft for spans over 15 ft.; rollers without uniform live-load except for floorbeam moments of 18-ton roller.

Figures in parentheses ( ) are ratios $\frac{\text{Load or moment from truck}}{\text{Load or moment from 13-t. roller}}$

Figures in brackets [ ] are ratios $\frac{\text{Moment from truck}}{\text{Moment from uniform L.L.}}$

TYPE OF LOADING		20-ton truck	17-ton truck	14-ton truck Dump-cart type	10-ton truck	13-ton roller No U.L.L.	18-ton roller No U.L.L.	Uniform Live-Load
WHEEL CONCENTRATION		14 (1 75)	10 (1 25)	12 (1 5)	8 (1.0)	8.0	11 0	
	Span, ft.							
MOMENTS	10	104 (2 08)	74 (1 48)	89 (1.78)	59 (1 18)	50	69	21
	12	124 (2 08)	89 (1 48)	107 (1.79)	71 (1 18)	60	83	29
	15	155 (2 07)	111 (1 48)	133 (1.78)	89 (1.19)	75	103	45
	20	206 (2 04)	147 (1 45)	176 (1.74)	118 (1.17)	101	138	81
	30	343 [1 90]	262 [1 45]	279 [1.54]	191 [1.06]	180	246	181
	40	509 [1 61]	405 [1 28]	405 [1.28]	287 [0.91]	260	356	317
	50	696 [1 42]	572 [1 16]	550 [1.12]	400 [0.82]	340	469	492
	60	913 [1 30]	768 [1 10]	725 [1.04]	540 [0 77]	421	581	701
FLOOR-BEAM MOMENTS (10-ft. panels)	Width, ft.						18-ton roller with U.L.L	
	15	106 (2 04)	78 (1 50)	93 (1.79)	71 (1.37)	52	76.5	
	20	169 (2 22)	128 (1 69)	134 (1.76)	115 (1.51)	76	122 8	
	25	243 (2 36)	188 (1.82)	216 (2 10)	169 (1.64)	103	178	
	30	327 (2 60)	257 (2 04)	291 (2 31)	232 (1.84)	126	242	

in designing bridges. While the uniform live-load is generally omitted in design when using a roller (except possibly when an 18-ton roller is used on city bridges), the writers feel justified in using a uniform live-load of 100 lb. per sq.ft. as a possible load that might be present simultaneously with the trucks.* There are several reasons for this assumption: three or four inches of well packed snow or ice would give 15 or 20 lb. per sq.ft.; timber might be piled alongside of the roadway for repairing an adjacent roadway and sidewalk; the assumption of a uniform load provides for all other traffic—such as trailers, if the truck is being used as a tractor, or a horse team near the truck; and, in general, the practice of using the uniform live-load simultaneous with the concentrations serves as a load factor-of-safety.

The moments in the accompanying table are for a width equal to the assumed width of truck or roller. *The moments include impact,* taken as 25% of the live-load in the case of the roller, and 150 ($L + 300$) in the case of the motor truck, L being the loaded strength of span in feet.

From this table, it is readily seen how these trucks are loading most bridges considerably beyond the loads employed in design. Considering the elastic limit of steel as about 32,000 lb. per sq.in., and our designing stress at 16,000 lb. per sq.in. in tension, it can be seen (from the columns showing ratios of moments of the trucks and rollers) how near the elastic limit a great many bridges are being worked. Especially is this true of the floor-beams and stringers, where the ratios of actual loads to designing loads run high, and it should be borne in mind in examining the table that the truck moments on the floor-beams do not take into account the case of two trucks passing.

While in the table of comparative moments a higher impact percentage has been used in figuring the trucks than in figuring the rollers, yet the moments produced by the trucks are so great that they would still be excessive if the impact effects were reduced to those employed for the rollers. It must be remembered that the roller was a slow-moving load and the resulting impact stresses were accordingly low; 25% of the live-load ought to cover the impact effect for an ordinary roller. The modern truck is capable of operating at a rate of about 12 mi. per hr., and the driver seldom if ever slows down the machine when on a bridge. An impact allowance of 50% would probably be required to cover the resulting stresses. The jar caused by these heavy trucks is often felt in houses set far back from the street, even when the pavement is asphalt in good condition, and the corresponding effect on a steel bridge can readily be imagined.

In the course of an investigation of the strength of a series of old highway bridges using truck loads similar to those given in the tables, it was found that the older bridges were not designed with uniform strength throughout to take care of the loads of today; and no doubt these old highway bridges referred to are typical of highway bridges in general. The floor-beams and stringers often are found to be considerably weaker than the main girders or trusses. The increase in loading due to the trucks shows most on the floor-beams and stringers because of the large percentage of load concentrated on the rear axle,* and the capacity of the bridge is largely limited by these members.

Recommendations

Posting Capacity of Existing Bridges—Since the older bridges are now carrying loads considerably in excess of the loads for which they were designed, and since the modern loads introduce new forces on our bridges in the way of impact, centrifugal forces, braking effects, etc., it is urgently desirable as a safety provision that bridges be posted for their permissible loading.

Posted signs at the approaches of highway bridges should state the heaviest total weight of loaded truck permissible. Drivers should know the weight of their trucks empty, the amount of load on the heavier axle, and the total capacity. As a rule, drivers lack this essential information.

Loadings for Future Design—For future designs some departures must be made by engineers to conform to the modern conditions. The following requirements are suggested:

Class A bridges to be designed for a 20-ton truck as per diagram, surrounded by a uniform live-load of 100 lb. per sq.ft., to take care of heavy city traffic.

*The uniform live-load is considered as loading the clear roadway only on the area surrounding that assumed as occupied by the moving truck. For spans exceeding 60 ft. in length this uniform live-load could be materially reduced in amount.

*In the case of dump carts, over 80% of the total load is usually on the rear axle

Class B bridges to be designed for a 12-ton truck as per diagram, surrounded by a uniform live-load of 100 lb. per sq.ft., to take care of suburban and state-road traffic.

Class C bridges to be designed for a 6-ton truck with distribution of load on axles similar to those shown, surrounded by a uniform live-load of 80 lb. per sq.ft., to take care of light country traffic.

If the clear roadway is wide enough to permit two trucks to pass, the floor system should be designed of corresponding strength, roadways over 16 ft. wide in the clear would come under this provision.* Class A and Class B bridges should provide for specified trolley loads in localities where such loads prove heavier than the truck loads. The bracing on these bridges should be effectively riveted stiff members. The planking should be well anchored and the floor-beam should be amply braced against stresses induced by sudden braking. All connection details should be worked out so that bracing members will prove efficient against vibration and lateral sway.

The dump truck will always require a heavy floor system if the scheme of dumping from the rear is adhered to, because of the large percentage of load balanced over the rear axle. Some form of center or side dump could be devised which would give more favorable concentrations for floor-beam and stringer design.

Class B loading should prove ample for almost any truck, and it is recommended as the most generally applicable type of loading. It should prove satisfactory for the occasional operation of any of the heavier types of trucks. A bridge designed for two Class B trucks passing each other will not be much heavier than most Class B bridges designed under the older types of loads, and the weight will be much better distributed to give a bridge of uniform strength throughout.

FUTURE INCREASE IN TRUCK LOADS?

After all, the above loads will not take care of all possible increases in highway loads unless legislation is enacted limiting load concentrations. There might be no limit to these concentrations if truck manufacturers are permitted to continue unrestricted. This would appear to be a matter of State regulation and surveillance. To blindly design bridges to take care of uncalled-for future increases in loading would involve a wasteful expenditure of money; and railroads and other corporations owning bridges, and finally the taxpayers, would be the ultimate losers.

A Bit of Early American Water-Works' Equipment

An old gate valve which was a part of the appurtenances of the old cast-iron water-storage tank of the Manhattan Co., New York City, described in ENGINEERING NEWS of July 23, is shown in the accompanying illustration. We have been unable to obtain any exact information as to the time this valve was installed, but if it was as old as the tank it dated back to the beginning of the last century.

The body of the valve was of cast iron, the stem, yoke rods and bolts of wrought iron, and the gate itself was a sheet of cast iron connected to the screw stem by a loose bolt. Although all the company's street mains were of wood—bored logs, yet the tank fittings were all cast iron.

Cast-iron water pipes were made and used for some purposes as early as the middle of the 18th century, but curiously enough were objected to for mains carrying a potable water supply as unhealthful. In the latter part of the 18th century and the first part of 19th century, when the London water pipes began to give out because of increased pressures, it was proposed to substitute pipes of bored stone for the wood mains, as the popular clamor against iron pipes was formidable. Patents were granted to two or three inventors for stone-pipe boring machines, and considerable money was invested in the industry.

EARLY WATER-WORKS GATE VALVE

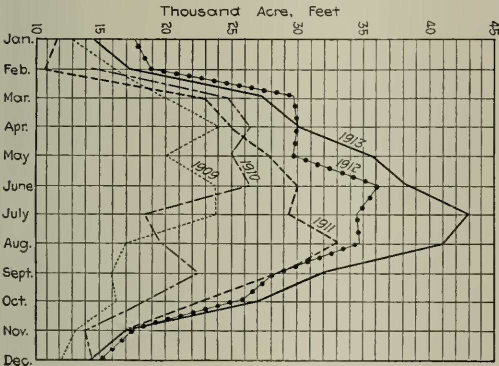
For the photograph shown we are indebted to Alfred D. Flinn, Deputy Chief Engineer of the Board of Water Supply of the City of New York. Mr. Flinn and other officials of the Board of Water Supply probably would have liked to see the old valve preserved in some museum as a relic of the city's history, but the city's historical societies could not be interested in a mere engineering curiosity, and the old valve was broken up for junk.

*[illegible]

Irrigation Operations of Imperial Water Co. No. 1 for the Year 1913

Intensive cultivation on land below sea level in what only a few years ago was a sun-parched desert has been made possible by diverting the water of the Colorado River into that portion of the extreme southern portion of California which is now known as the Imperial Valley. Water for this district is supplied wholesale by the California Development Co. to a number of companies which distribute it to farmer's canals. We have received from Ray S. Carberry, Superintendent of Imperial Water Co. No. 1, a copy of his annual report for the year 1913 and have taken from the report a number of unusually interesting and valuable operating and cost facts and figures.

The company operates 330 miles of canals. These canals cover 115,520 mi. of irrigable land. During 1913



Monthly Deliveries of Water to the Imperial Water Co. No. 1 for the Years 1909 to 1913, Inclusive

the company executed 33,964 orders for water and paid the parent company for 337,349 acre-ft. of water, which was delivered to 101,796 acres of crops. On this work an average of 172 men were employed per day for a working year of 300 days.

The accompanying diagram shows the amount of water delivered to the company by months during the past five years. The maximum demand in 1909 and 1910 was in April, but since then it has ranged from June to August. In 1913, July was the maximum month.

Unaccounted-for water in 1913 amounted to 11.06%, which was the difference between the measured amount received by the company and the measured quantities delivered to individual consumers. For earlier years the unaccounted-for water was as follows: 1912, 13.9%; 1911, 15.9%.

The 11.06% of water not accounted for in 1913 represented a gross charge against the company of \$20,737, reduced to \$1996 by an allowance of 10% on the part of the parent company.

The difference between what may be termed the wholesale and retail deliveries is explained in Mr. Carberry's report as follows:

The difference of \$20,737.47 may be accounted for in seepage, evaporation, waste, stock water and error in measurements, of which the waste water is a principal factor in crowding our ditches during the peak load, which results in considerable overflow of the banks, occasioned by the stockholder's ditch, as well as the company's ditch, being in an undesirable condition for conveyance of the maximum amount of water at that time of the year.

Your Board, by authorizing the charging for stock water, has saved several dollars; not that the charge for any large amount was made, but the fact that stock water was charged for reduced materially free irrigation under pretense of stock water.

The errors of measurement will be further investigated and studied in hopes that some further information may be given to you relative to this condition.

Cost figures for cleaning canals, clearing canals, cutting brush, widening and shaping banks, "Canal V'ing," dredging and for automobiles are given in the report as follows:

CLEANING CANALS—During the year we cleaned 339 mi. of canal, at a cost of \$35,826, or \$105.68 per mi., as compared with 343 mi. of canal at a cost of \$88.61 per mi. for 1912, or 465 mi. at a cost of \$60.64 in 1911, or 562 mi. at a cost of \$43.81 per mi. in 1910. The gradual increase of cost may be attributed to the increased amount of material necessary to be removed by cleaning occasioned by increased capacity required at such times as the increased quantity of silt, growth and difficulties of labor conditions, effect this class of work.

CLEARING CANAL on 50 miles cost \$1984, or \$38.68 per mi., as compared with 101 mi. at a cost of \$80.58 per mi. in 1912, or 194 mi. at a cost of \$35.39 per mi. in 1911. This decrease is accounted for by the fact that little clearing and more cleaning has been done, therefore increasing the cost of one and decreasing the cost of the other.

CUTTING BRUSH on 300 mi. of canal cost \$1054, or \$33.51 per mi., as compared with 200 mi. at a cost of \$18.98 per mi. in 1912, or 392 mi. at a cost of \$20.71 per mi. in 1911, or 346 mi. at a cost of \$43.45 per mi. in 1910. The increase per mi. in this class of work is attributed to the fact that considerable heavy growth was cut during the year that had not been attempted during the previous years.

DISC AND GRADER—During the year we have continued the use of disc and grader outfits on our canal banks, with the result of widening the banks, removing the "V" rolls, discouraging the growth, and in some places making the banks suitable for travel, and for the use of mowing machines to keep down the growth. This work during the year has cost \$4851 in covering 296 mi. of canal, or \$16.39 per mi., as compared with 280 mi. at a cost of \$14.88 per mi. for the previous year.

CANAL V'ING still proves the best method for cleaning the canals where same is practical. The detailed amounts and costs of this work are as follows:

	1910	1911	1912	1913
Total cost	.....	\$21,437.78	\$26,142.08	\$26,471.20
No. of miles of ditch V'd	362	364	481	431
Cost per mi. for V'ing...	\$25.94	\$16.76	\$17.05	\$21.99
Cost per mi. repairs to engine	15.66	16.29	13.43	14.31
Cost per mi. repairs to V's	5.56	5.09	3.93	2.38
Cost per mi. fuel and oil	.....	5.96	6.52	6.69
Cost per mi. Mexican labor	13.58	14.80	13.42	16.04
Total average cost per mi.	\$60.74	\$58.91	\$54.35	\$61.41

DREDGING—During the year the Stockton dredges and the Austin dredge, referred to in my report of a year ago, have been practically in continual operation. On the first of August an additional Stockton dredge as purchased, which also had been in continual operation since that time. During the latter portion of the year a contract was made with the Schlatter Dredge Co. for experimental work with their dredge at 15c. per yd.

As this method of work is comparatively new, it may be of interest to note that the Stockton dredges have worked on 37.3 mi. of canal and excavated 188,708 cu.yd. of material at a cost of 10.7c. per yd. Austin dredge worked on 33½ mi. of canal, removed 96,712 cu.yd. of material at a cost of 16.8c. per cu.yd., to Water Company No. 1, while the Schlatter dredge worked on four miles of canal, removed 3862 cu.yd. of material for 15c. per cu.yd. The total mileage for the year for these dredges amounts to 74.8 mi., total yards for these dredges for the year amounts to 287,282 cu.yd. and total cost to Imperial Water Co. No. 1 is \$37,150.98, or 12.93c. per cu.yd.

The repairs on the Stockton dredges have amounted to \$1353 for operating 17 months, or \$79.40 per month, which is quite nominal compared with repairs needed for caterpillar engines. It is certainly a question as to how we would have been able to deliver water throughout the past year had not this 287,282 cu.yd. of material been removed.

[illegible] you will note that we have worked on [illegible] as compared with 118 mi. in 1912, [illegible] while our statement shows but [illegible] mi. in our system; this gives you some idea of the amount of work required to maintain the delivery of water as long as the peak load remains in the latter part of the summer.

AUTOMOBILES—During the past four years we have used three cars and they have traveled 66,331 mi., the cost of [illegible] as follows:

	Overland cars 1910	1912	Hupmobile
[illegible]	[illegible]	[illegible]	[illegible]
Miles [illegible]	19,147	22,858	24,026
[illegible] gal.	1,166	1,814	1,461
Total [illegible]	31,123	[illegible]	[illegible]
Total [illegible] cost	1,860	1,411	1,027
[illegible] cost per mi.	[illegible]	0.0617	0.0427
Total [illegible]	[illegible]	12,413	41,913
Total cost per mi.	0.1688	0.1054	0.0796
Average mi. per gal. of gasoline	9.59	12.39	16.14
Average cost per mi. for [illegible]	[illegible]	0.0187	0.0125
[illegible] per mi. of travel	0.0511	0.0250	0.0213

The distribution of irrigation costs for the past three years and the acre-ft. of water delivered and the cost of water per acre-ft. were as follows:

The acreage of crops in 1913 was 101,796, divided as follows: Alfalfa, 59,279; barley, 19,257; corn, 12,[illegible]; cotton, 1741; melons, 3125; vineyard, 910, asparagus, [illegible]; truck, [illegible]; miscellaneous, 1104.

The increased amount of water used per acre of crop, as shown in the table, is "attributed to the increase in summer crops and the decrease in winter crops; more alfalfa, corn and cotton and less barley."

	1911	1912	1913
Canals	$94,756.11	$[illegible]	$56,698.82
Dredging			35,320.61
Distribution of water	23,158.81	[illegible]	20,946.[illegible]
Live stock, etc.	7,664.6[illegible]		747.68
Salaries, general	12,443.32	13,[illegible]	13,[illegible]05.67
Engineering			4,5[illegible].96
Zanjero houses and phones	1,[illegible]50.3[illegible]	2,1[illegible]	933.64
Tools and repairs	1,386.1[illegible]	1,7[illegible]	3,430.[illegible]
Expense, general and miscellaneous	[illegible]	[illegible]	[illegible]
Structures	1[illegible],423.80	[illegible]	[illegible]
Equipment, new			11,6[illegible]
Total	$[illegible]	$[illegible]	$[illegible]

COMPARATIVE COST FOR PAST FOUR YEARS

Year	Total cost	Acre-ft. delivered	Cost per acre-ft. delivered, cents	Acre-ft. per acre*
1910	$171,6[illegible].11	236,161	73.[illegible]	[illegible]
1911	15[illegible],[illegible]31.5[illegible]	274,66[illegible]	[illegible]	[illegible]
1912	158,454.6[illegible]	318,12[illegible]	[illegible]	3.15
1913	[illegible]	337,3[illegible]	[illegible]	3.[illegible]

We are informed by Mr. Carberry that he will gladly mail copies of his complete report to any engineer requesting him to do so.

Worcester Water-Works Plant and Operating Methods

SYNOPSIS—The city of Worcester, Mass., does all its water-works construction, repair and maintenance by municipal day labor. In this article is a description of the organization, plant and operating methods, together with notes on local water-works practice. [illegible] independent bureaus of the Water Department, one under a Water Commissioner and one under a Water Registrar; work of the 12 divisions under the Water Commissioner, work of the Water Registrar's bureau, regulations governing the use of water, shop, stables and [illegible], use of cement-lined [illegible] pipes, [illegible] boxes, etc.

The city of Worcester, Mass., is notable because for many years it has constructed practically all its public works by municipal day labor. Yet there is no public-works organization as a whole. There are a City Engineering Department, Street Department, Sewer Department, Water Department, each independent. Aside from the actual survey work and work preliminary to construction, the City Engineer acts merely in an advisory capacity, and has no power to enforce his recommendations. Every department works out its own problems largely in its own way. Some of those [illegible] by the Water Department are given in the following columns.

The population of Worcester served with city water is about [illegible]. The [illegible] consumption of water is about [illegible] billion gallons, [illegible] of which is metered. The average daily consumption is nearly [illegible] million gal., and the per capita consumption is about [illegible] gal. per day. The whole cost of supplying water, including maintenance and interest, runs about [illegible] per million gallons. The supply comes from several reservoirs by gravity; there are no pumping stations.

ORGANIZATION OF THE WATER DEPARTMENT

There are two independent bureaus of the Water Department, one under the Water Commissioner, George W. Batchelder, which has charge of reservoirs, distribution system, operation and maintenance; the other bureau is under the Water Registrar, George C. Hunt, and looks after the reading of meters, collection of water rents, etc. The organization of the bureau under the Water Commissioner is shown in the accompanying sketch, Fig. 1.

All orders given in this bureau must have the approval of the Water Commissioner. Acting under the direction of the Water Commissioner, the General Foreman has supervision over Divisions 1 to 9 inclusive, shop and emergency calls, stock and supplies, pipe yard, service pipes and stop boxes, fire pipes and hydrants, repairs, hydrant inspection, shop accounting and construction. Foremen in charge of Divisions 10, 11 and 12, meter repairs, [illegible] pipe inspection and reservoirs, receive their instructions and make their returns directly to the Water Commissioner.

WORK OF THE VARIOUS DIVISIONS

Each division is in charge of a foreman who acts under the orders of the Water Commissioner, as transmitted to him directly or through the General Foreman. A list of the various divisions, their work and the approximate number of men employed in each, follows:

DIVISION 1—SHOP AND EMERGENCY.—This division includes the shop and emergency crews, except as otherwise provided for. The force employed is about 25 men. Emergency calls are here taken care of and the emergency men act under orders of the division foreman and report to him, day or night, any serious disturbance in the distribution system, such as sudden drops in pressure, reported leaks, broken hydrants, etc.

DIVISION 2—STOCK AND SUPPLIES—This division has charge of all stock and supplies at the East Worcester St. yard, which is adjacent to and part of the shop and stable layout. The division foreman furnishes all supplies when presented with properly signed requisitions, and is held responsible for the contents of stock room and yards. The men employed in this division are included in the 25 listed under Division 1.

DIVISION 3—PIPE YARD—All the large pipe, fittings,

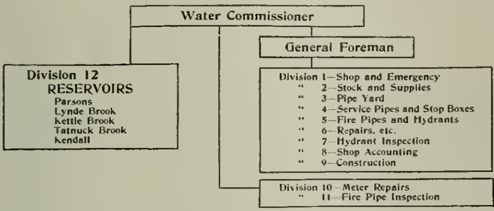

FIG. 1. ORGANIZATION SCHEME, WORCESTER, MASS., WATER DEPARTMENT

gate valves, specials, etc., are unloaded directly into dump cars and stored in the Albany St. yard, which is about a quarter of a mile from the other material yard, shop and stable. About $130,000 in stock is here kept constantly in hand. This yard is in charge of a subforeman who keeps in touch and is answerable to the foreman of Division 2. There are about five men employed in Division 3.

DIVISION 4—SERVICE PIPES—All installations of service pipes, small pipe extensions, resetting and regrading of service and stop boxes made necessary by street changes, and such other work as may be directed, are performed by this division. The whole force of the division is about 30 men, divided into five gangs, each in charge of a subforeman.

DIVISION 5—FIRE PIPES AND HYDRANTS—This division has charge of installing fire pipes, elevator pipes, fire hydrants, standpipes, flushing hydrants, drinking fountains and watering troughs, and has charge of the maintenance and repair of all these except drinking fountains and standpipes. The division force is about 18 men, divided into three gangs, each under a subforeman.

DIVISION 6—REPAIRS AND MAINTENANCE—This division has charge of all general repairs to service pipes, drinking fountains, standpipes, service shutoffs, removing and replacing meters, etc. The force consists of 10 men in two gangs, each under a subforeman.

DIVISION 7—HYDRANT INSPECTION—Five men have the work of inspecting, maintenance and minor repairs to fire hydrants.

DIVISION 8—SHOP ACCOUNTING—The men in this division, four in number, are included in the force under Division 1. This division has charge of all accounts kept at the East Worcester St. shop and yards, and is in reality a subdivision of Division 1, although its chief is responsible only to the Water Commissioner and General Foreman.

DIVISION 9—CONSTRUCTION—All construction work, and this includes construction work on reservoirs and new reservoirs, the installation of mains, replacements, repairs, maintenance, etc., employing 150 men, is done by this division, under four general foremen. The department owns an Austin trenching machine, the work of which was referred to in ENGINEERING NEWS, Aug. 6, p. 312, and numerous other uptodate equipment, which is used by the construction division.

DIVISION 10—METER REPAIRS, LIGHT MACHINE WORK, ETC.—This division has charge of the testing and repairing of all meters, which employs three men. The meters are installed by the employees of Division 4, as a part of the service connection. The house inspection and reading of meters is done by the men under the Water Registrar, as hereafter described. The meter-repair division makes tests of all new meters delivered at the shop, and makes necessary repairs to all meters taken off of services for any cause. The foreman keeps a careful record of all meters received at and delivered from his division, and sends copies of these records to the office of the Water Commissioner.

DIVISION 11—FIRE-PIPE INSPECTION—This is a one-man division, although he may have assistants assigned when necessary. He sets all small meters on fire-service lines, has charge of all inside valves on fire-protection services, reads and inspects meters on fire-service pipes, the Venturi meters at reservoirs, and has entire charge of the inspection of fire-service pipes. He makes daily reports direct to the Water Commissioner.

FIG. 2. STOCK YARD ON EAST WORCESTER ST.: TOOL HOUSES AND SHEDS

Division 12—Reservoirs. This division includes the caretakers or foremen in local charge at the various reservoirs, each of whom reports direct to the Water Commissioner.

General.—Under the General Foreman are three men detailed to make general emergency repairs. There is also a spare foreman ready to take the place of any regular foreman, assume emergency duties and perform any service he may be directed to by the Water Commissioner or General Foreman. Every man in the department is assigned to one or the other of these divisions and takes orders from the foreman in charge of that division. This, in general, is the rule of the organization, yet in cases of emergency all men are expected to carry out such directions as may be given them by the Water Commissioner, General Foreman, or such foreman as shall be in charge at the time.

Bureau of the Water Registrar

This bureau is locally called the Water Income Division of the Water Department. The bureau employs six meter readers and two inspectors. Every meter is read once a month. The meter readers are employed every working day in the year in reading meters, and each is held personally responsible for the condition of meters in his territory. The reader makes returns of the meter readings to the office each day and he also posts the readings on a card on the premises of the owner, so that the owner may always know the quantity of water being consumed each month.

The inspectors' duties are to inspect the fixtures in houses whose month's consumption is out of the ordinary. Each day the readings turned into the office by the meter readers are compared in the office, and, if the consumption of any house is much in excess of the average, and there appears no reason for the increase, an inspector is immediately sent to examine the house-service fixtures. If the fixtures are found imperfect, the owner is immediately notified of the exact condition, thereby being able to take advantage of this information if he desires.

The city has at present about 18,000 meters. As Mr. Hunt says, the financial success of a water department depends largely upon the accuracy of the water meters and it is of the greatest importance that the meters be examined and tested frequently. About 3000 meters are taken out each year and repaired at the expense of the Water Department, unless they have been injured by frost or otherwise through negligence of the property owner. If the meter is worn out, a new one is installed at the expense of the owner. The total cost to the department of meter repairs in the year 1913 was $10,315.

Regulations Governing Use of Water

There are the usual ordinances governing the introduction and use of water, all applications being sent to and handled by the office of the Water Registrar. All service pipes and appendages laid in the street are furnished and maintained by the city. From the street line to the outlet of the meter on the house side of the stopcock all pipes and fixtures are furnished, placed and repaired by the city at the expense of the owner. Bills for metered water are payable semiannually, in March and September. If bills for water or fixtures are not paid within 40 days after notice, the water is shut off and an additional charge of $2 made. Water users are charged $2 for shutting off and letting on water, when making repairs on premises, or for any other reason. All injuries to service pipes, street mains, hydrants, or other fixtures caused by ex-

Fig. 3. Shop and Stable, Worcester, Mass., Water-Works

FIG. 4. ALBANY ST. STOCK YARD, WORCESTER, MASS., WATER-WORKS

cavations in putting in sewers, drain, or other pipe are charged to the owner of the premises for whom the work is done. Installing meters is optional with the owner. All private fire services are metered at the expense of the owner.

Shop, Stable and Yards

Fig. 2 shows the East Worcester St. yard of t'e Water-Works Department. On the right are wagon and automobile sheds and on the left a row of individual tool houses, one for each service pipe gang. The corner of the building on the right is the stable and on the left the shop. Fig. 3 is a view of the shop and stables taken from the rear of the yard. Fig. 4 shows the Albany St. stock yards.

The shop was built in 1908 and is a thoroughly uptodate water-works repair plant in every respect. On the first floor are the offices, general shop and storage room for tool chests, etc. On the second floor are the meter repair shop and the meter-testing room. Fig. 5 shows the interior of the meter repair shop, which is equipped as shown with lathes, drills, grindstone, etc., for light ma-

FIG. 5. INTERIOR OF METER REPAIR SHOP, WORCESTER, MASS., WATER-WORKS DEPARTMENT

Fig. 6. Storeroom, Worcester Water-Works Shop

chine work. On the third floor are carpenter and woodworking shop and storerooms. The fourth or top floor is all storeroom, as shown in Fig. 6. Everything is orderly and well arranged as may be judged from the illustrations, which were taken under the direction of one of the editors, without previous warning to the shop foremen.

In the basement are additional machine tools and equipment for handling, repairing and storing the heavier appurtenances. From this basement of the shop there is a subway to the basement of the stable, which is utilized as a storeroom for service pipe, cocks, connections, hydrants and hydrant parts, etc., as shown in Fig. 7. Here is kept emergency repair equipment for serious breaks.

On the main floor of the stable overhead is a garage, as most of the vehicles now used by the Water Department are motor-driven. There are eight motor vehicles in all, two touring cars, one runabout, one 3-ton truck and four smaller trucks like the one shown in Fig. 3.

These small trucks are used for emergency work, but to be always ready to answer hurry calls the emergency wagon shown in Fig. 8 stands with harness ready to drop in place. This wagon is equipped with various kinds of apparatus for shutting gate valves, and making hasty repairs, lanterns, tools, etc. To answer these emergency calls, a crew of five men is always on duty, working in 8-hr. shifts.

The apparatus for quick closing of main gate valves consists of a rod wrench, which is put down the manhole, a wrought-iron frame fitting in the manhole opening, with a center ring to hold the wrench rod, and an ordinary wagon wheel which fits over the top of the wrench rod. The valve can be closed very readily and very rapidly by turning the wagon wheel.

Over the main floor of this building is the stable proper which is now used by but one or two horses.

Notes on Operation

Service Pipes—All service pipes are cement-lined 1-in. and 1¼-in. wrought-iron pipe. The lining is done by the municipal labor crews in the winter when other work is slack. The cost of the pipe with cement lining per lin.ft. is 4.75c. for 1-in. and 7.84c. for 1¼-in. pipe. The pipe is sold to the property owners at 10% increase over these prices.

All service connections are made by lead goose-neck connections with the mains, to take the water-hammer and shock. There are now no curb cocks inserted for cutting off house services. Instead, a regulation corporation cock is inserted alongside the main, in the street. The cock is inclosed in a cast-iron box made in two sec-

FIG. 8. STABLE, WORCESTER WATER WORKS DEPARTMENT; EMERGENCY WAGON

tions (Fig. 9), one tapered, straddling the service pipe and resting against the main (A), and the other (B) cylindrical with a flanged circular top, which lies flush with the street surface. The tapered lower part admits of adjustment to the depth of main below street surface. It is stated that little or no trouble is experienced with this type of service cut off.

FIG. 9. SERVICE CONNECTION BOX

The Department owns two or three large pipe-tapping machines and is in every way equipped to do all the construction and repair work often done in other cities by contract.

Mine Cave-ins are so general, almost continual, and the resulting casualties so high, that the United States Bureau of Mines has just issued a circular discussing safety measures applicable to the circumstances. There were employed in and about metal mines of the United States in 1912, 169,199 men, of whom 110,056 worked underground, and 59,143, on the surface. There were 661 fatal accidents—522 underground and 139 on the surface; of these, 212 were caused by falls of rock or ore, representing 32.1% of the total number of men killed on the surface and underground, and 40.6% of the number killed underground. Copper mines showed the largest percentage of men killed from this cause, with iron mines second. Lead and zinc mines showed about the same percentage of fatalities as gold and the miscellaneous metal mines, and were third in order. This indicates that the greatest number of accidents from falls of rock or ore occur in ore bodies of great width.

As in the case wherever men are employed, the personal equation can prevent more accidents than a superabundance of mechanical safety devices. A knowledge of the nature of the ground and the proper method of timbering is essential to efficient working. That rock or ore falls because of lack of support is axiomatic, and the circular claims that the usual tendency whether drifting or stoping is to use too little timber, or to wait too long before placing the timber. All loose rock should be removed from the face, back, and sides as driving progresses, and should be done immediately on returning to the place after blasting. A common cause of falls is failure to use enough blocking about the timber. Where the ground has a tendency to fall or slough off, there should be no space left over the timber sets or lagging. All loose rock should be pulled down, and the spaces filled in solidly with rock or tightly blocked with pieces of timber. The dropping of pieces no larger than a baseball has killed men.

No infallible rules for detecting dangerous ground can be laid down, on account of varying ground conditions in different mines, and even within the same mine. The usual method of spotting a dangerous piece of rock overhead is to tap the suspected place (gently at first) with a pick handle. If the sound given out indicates that it is loose it is called a "drummy," and although it may stand for years, certainty demands that it be pulled down at once. A study of the accidents occurring in a certain large mine showed that most of the falls occurred in what was thought to be safe ground. The obvious reason was that in treacherous ground greater care was exercised. The company owning this mine arranged for closer inspection of workings, and thereafter used twice as much timbering. It is said that after a six-months' trial the reduction in the number of accidents from falls amounted to 50%.

A Large Reinforced-Concrete Mat Foundation for a Seventeen-Story Office-Building

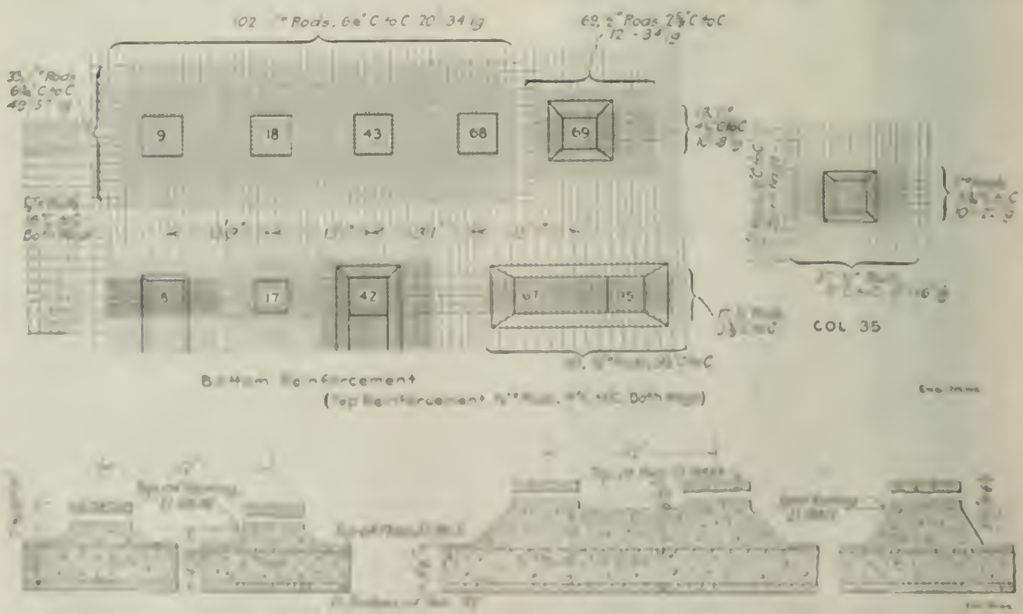
The two accompanying drawings represent the foundation slab or mat of reinforced concrete on which rests the 17-story office-building portion of the new passenger terminal of the Michigan Central Ry. at Detroit. This unusual type of foundation was employed because the character of the subsoil did not promise any better results from deep foundations, piers, piles, or the like, than could be secured with shallow footings, and at the same time a base slab was desirable to forestall unequal settlement. The advantage of economy lay with the mat foundation by a large margin.

Footing Plan, West Half of Mat

Elaborate piledriving and loading tests and soil-loading tests were made on the site of the proposed station before the foundation design was settled on. The site is a mile or more from the central business district of Detroit, and no high or heavy buildings exist near-by, so that reliable precedent was lacking. The deep bed of clay underlying Detroit, averaging over 100 ft. to rock, varies in physical character so much that the downtown practice in heavy foundations could not be taken as applicable to the case.

The conclusion from the soil-loading tests was that at cellar level a loading of 2 tons per sq.ft. of loaded area could be carried without appreciable settlement. The pile tests, on the other hand, did not indicate that any advantage in stability or economy would result from the use of piles; at the same time there remained some doubtful features in the behavior of the piles under long-continued test loading, which suggested that working on piles should be kept very low, possibly below 15 tons per pile. The engineers of the railway company concluded in favor of a mat footing, and their opinion was confirmed in the report of Olaf Hoff, who was called in consultation.

The mat footing as designed for the 17-story building is a 42-in. slab of concrete reinforced at top and bottom by continuous layers of rods. Under the single-story waiting-room and concourse portions, north and south of the office-building, the slab is 30 in. thick. At the edges the slab is extended somewhat beyond the footing-width of the outer columns, to prevent any possible bogging action, i.e., settlement at the edges of the mat from lateral flow of the clay subsoil. The bottom of the



Reinforced-Concrete Mat Foundation under Michigan Central Terminal and Office-Building, Detroit, Michigan

mat (Elev. 92) is 2 ft. below the mean level of the Detroit River (Elev. 94), and 27 ft. below ground level in front of the building.

The loads of the columns bear on the mat through spread reinforced-concrete footings proportioned as if for direct soil support, but at the higher loading of 4 tons per sq.ft. This is intended to reduce the bending moments in the mat. The reinforcement of the mat is proportioned empirically.

The mat was built by concreting direct on the floor of the cellar excavation. It was necessary to place the concrete in sections (defined by vertical bulkheads), but the continuity of the reinforcement makes the mat in effect a monolith.

The mat was built in June, 1912. Up to the present, no settlements of any kind have been detected by careful leveling.

The design of the foundation is due to George H. Webb, Chief Engineer of the Michigan Central Ry. The company's architect, Edward W. Smith, and W. B. Goddard, Jr., Structural Engineer, collaborated in the work, and carried out the detail designing. Geo. A. Fuller Co., contractors for the entire station building, constructed the foundation.

Track Elevation in Chicago

The elimination of grade crossings of streets and railways in Chicago represents one of the most extensive and costly engineering works in the country. The work has been in progress for some 22 yr., and the report of the city's Commissioner of Track Elevation in 1911 showed that the work then done amounted to 110 miles of road and 843 miles of track, at a cost of $66,256,000. A future total of 192 miles of road and 1265 miles of track was then estimated.

Figures compiled recently by R. H. P. Ford, Engineer of Track Elevation of the Chicago, Rock Island & Pacific R. R., show that at the present time about 1000 miles of track have been elevated, and 1285 subways built, at a cost of over $75,000,000, while when completed, this work will comprise some 2185 miles of track and 2600 subways, with a total cost of $175,000,000. Of this enormous cost, about 98% is paid by the railways, 1.7% by the city and only 0.3% by the street railways and other public-service corporations. The city's share is in assuming all costs of damages to adjacent property due to the track elevation, and the corporations bear the expenses of the necessary changes to their property in the streets and alleys.

In other cities there are more or less costly sections of track elevation (or sometimes track depression) to eliminate grade crossings at certain points, but in Chicago the work comprises long continuous stretches of line, and the project as a whole covers practically all railway lines within the city limits.

The flat country in which Chicago is located led naturally to the early railways approaching and entering the city on the ground level, and they were extended gradually through the city to terminal points, being built either in the streets or on purchased right-of-way. At one time there was a policy of elevating important streets and carrying them across long groups of tracks by viaducts, but this was abandoned some years ago, as the long approach grades were unfavorable to street traffic, while the multiplication of elevated approaches (both on the viaduct streets and on intersecting streets) would cause serious depreciation of value of property. Some of the viaducts have been replaced by subways, and while a number still remain, no new ones have been established for a long time, the fixed policy being the ultimate elevation of all the railway lines.

The Chicago track-elevation movement dates from 1892 when the Illinois Central R.R. secured an ordinance for the elevation of its tracks between 51 St. and 67 St., in order to be able to handle the heavy local traffic during the Columbian Exposition. The city created its track elevation department in 1897, and this was conducted until 1907 by the late John O'Neill, who realized that this was a matter of a definite and comprehensive policy of track elevation for the entire city.

The typical track-elevation work consists of a solid fill or embankment contained between concrete retaining-walls on each side and the concrete abutments of bridges over the streets. There is practically no viaduct work utilizing the space beneath the tracks. It is of a very comprehensive character, including main lines with from four to ten tracks, and in relation to these there are stations, terminals, yards and innumerable sidings and industry tracks. Further, the work has to be done largely in busy districts, and in all cases provision has to be made for carrying on the railway, street railway and street traffic. This involves special difficulties in the planning and execution of the work. At certain points it is complicated by railway-grade crossings. In some of these cases, the railway grades have been separated by means of a double-deck construction, one railway viaduct crossing above the other. In other cases, however, the conditions have not permitted such an arrangement, and it has been necessary to retain the railway grade crossing, but removing it from the street level.

For the numerous bridges across the streets, the designs vary on different roads. In some cases there are steel through bridges, with girders between the tracks, but this prevents any shifting of tracks or the placing of switches to accommodate future conditions, and will be a source of trouble when electrification of the terminal lines is commenced. In other cases, deck-girders or self-supporting through-floor steel spans have been used, which present no obstructions above the road bed.

Of late years the all-concrete subway bridge has come into use on several lines, the floor consisting of massive concrete slabs which are set in place on the concrete abutments and intermediate piers or bents by means of powerful wrecking cranes or derrick cars. These also provide an unobstructed floor. As different railways sometimes occupy parallel and adjacent right-of-way, many subways present the curious feature (and unfavorable appearance) of two distinct types of construction.

The track elevation in progress at different points of the Chicago railway system presents interesting examples of different designs and methods of execution for work of the same general class. The work must be done on a restricted right-of-way, with a frequent service of trains to be provided for. On account of the density of street traffic, the city will not permit the closing of more than a few consecutive streets at one time, so that a stretch of track-elevation work must be divided into sections, in each of which the operations are separate and distinct. This

complicates the work and the handling of trains, lengthens the time occupied by the work, and adds materially to the cost.

As far as the results are concerned, the railways benefit by greater facility of traffic, and the reduction of damage claims due to accidents at street crossings. The public benefits by the greater facility and safety of street traffic, and the traveling public shares the benefit gained by the railways. The city gains in the general improvement of its traffic conditions and in the greater safety of its population. In this respect, it is of interest to note that grade-crossing accidents in Chicago declined steadily from 19 deaths and 173 total personal accidents per million population in 1899, to 6 fatal and 39 total per million in 1911.

While it is true that the work of track elevation has to some extent been forced upon the railways by the city, much credit is due to the railways for their foresight in recognizing the necessity of the work and in cooperating liberally with the city. And it must be remembered also that practically the whole of the expense of this very costly work is borne by the railways. It is specially worthy of note that in the general policy of track elevation in Chicago and in the planning and execution of the various sections of work, there has been on the whole, the very desirable feature of harmony and cooperation between the railways and the municipal authorities.

Acceptance Test of a High-Duty Triple-Expansion Pumping Engine at Bissell's Point Station, St. Louis Water Works

By Geo. M. Peek*

In 1912, specifications were drawn for two new pumping units to be installed in Engine House No. 2 at Bissell's Point, St. Louis. These two pumps were to take the place of one old [illegible] bucket-and-plunger machine which was installed in 1891. This old engine was [illegible] by the [illegible] Foundry & Machine Co., of Philadelphia, at a cost of $[illegible]. It had a rated capacity of [illegible] gal. per 24 hr. against [illegible] lb. water pressure when supplied with steam at [illegible] lb. pressure. The tests on this engine showed it to develop a duty of 61,860,000 ft.-lb. of work per 1000 lb. of steam. The original boilers for supplying steam for this engine were [illegible] type. In 1898 these were replaced by four water-tube boilers fitted with inclined-grate stokers. The boilers carried a steam pressure of 75 lb. which was reduced, to a large [illegible], to [illegible] lb.

[illegible] April, 1912, bids were opened and the contract for the two new 20,000,000-gal. pumping engines, to be completed and erected on foundations prepared by the Water Department, was awarded to the Holly Manufacturing Co., of Buffalo, for $[illegible]. The specifications called for the completion of one unit in 10 months and the other in [illegible], but the company was granted an extension of time.

The contract called for a duty of 165,000,000 ft.-lb. of work per 1000 lb. of steam (160 lb. pressure and 100° superheat) when pumping against a pressure of 125 lb. in a discharge pipe whose elevation was 105.25 and with the elevation of water level in the wet well at 95. The engine was required to deliver all of the condensate back to the boilers. The contract called for a bonus of $1000 for each million foot-pounds of work done by the engine in excess of 165 million and a forfeiture of a like amount for each million the duty fell short of the guarantee. One unit was put in service in September, 1913, and was tested Apr. 23 and 24, 1914.

The design shows a vertical flywheel type with single-acting outside-packed plungers, each located under one

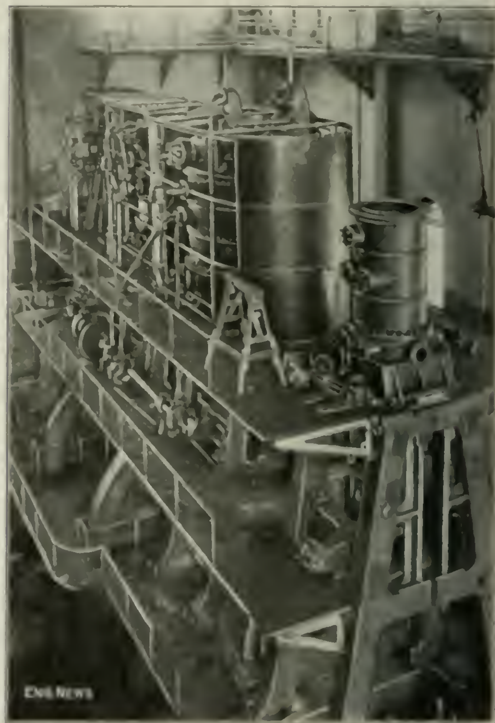


FIG. 1. THE 20,000,000-GAL. PUMPING ENGINE AT THE BISSELL'S POINT STATION, ERECTION NEARLY COMPLETED

of the cylinders. Each cylinder has a single piston rod and [illegible] distance rods connecting the plunger with the crosshead. The pump ends are arranged for direct flow and have removable steel valve [illegible]. This arrangement is shown in Fig. 2.

The valve gear is worked from a layshaft, which in turn is driven from the main shaft through bevel gears. All valves are located in the heads and, except the low-pressure exhausts, are of the multi-ported Corliss type. The low-pressure exhaust valves are poppets. All cylinders are jacketed and arranged so that the steam passes from the jacket of the high-pressure cylinder to that on the intermediate, then to the one on the low-pressure.

The cylinders are supported on A-frames, which extend

*[illegible] Engineer in [illegible], Construction Department, St. Louis Water Works, St. Louis, Mo.

Fig. 2. Valve Deck of New Bissell's Point Engine

to bedplates resting on top of the air chambers. The bedplates are arranged so that they may be supported on jacking columns in order that any air chamber may be removed without disturbing any of the superstructure of the engine. The plungers are semichilled and ground. Pump chambers are of ca t steel.

The pistons are of cast iron, in one piece, fitted with cast-iron rings, and are finished and polished on both sides. The cylinder heads are polished on the inside. The cylinders are covered with 85% magnesia insulation. The valve cages are of semisteel and the holding down bolts are of manganese bronze. The crossheads are of cast steel and are fitted with solid bronze shoes.

TABLE 1. DETAILS OF 20,000,000-GAL. HOLLEY PUMPING ENGINE; ST. LOUIS WATER-WORKS

1. Diameter of Steam Cylinders; 34, 64, 98 in.
2. Character of Metal; cast iron.
3. Thickness of inside shell; 1½, 1¾, 1⅞ in.
4. Width of Jacket Space; 1, 1, 1⅛ in.
5. Thickness of Outside Shell; 1⅝, 1⅞, 2 in.
6. Volume of Receivers; First, 206 cu.ft., Second, 291 cu.ft.
7. Thickness of Piston Head; 12 in. throughout.
8. Piston Packing Rings; Cast iron.
9. Number of Piston Rods; One to each Cylinder.
10. Diameter of Piston Rods; 8 in.
11. Stroke of Piston; 66 in.
12. Revolutions per Minute; 20.
13. Diameter of Steam Valve; 6, 9, 10, 12 in. Corliss, 21 in. Poppet.
14. Location of Valves, All in Heads.
15. Type of Valve Gear. Corliss with poppet exhaust on low pressure.
16. Size of Main Connecting Rod; 8 and 9¾ in. diameter.
17. Length of Main Shaft; 12 ft. 7½ in.
18. Diameter of Main Shaft; 23 [illegible] in.
19. Diameter of Main Journal; 20 in.
20. Length of Main Journal; 32 in.
21. Metal in Main Shaft; Fluid compressed steel.
22. Size of Cranks; Hub 33 in.; Web 30 in.
23. Size of Crank Pin Journal; 12½x11 in.
24. Diameter of Flywheel; 20 ft.
25. Weight of Rim of Flywheel; 30 tons.
26. Diameter of pump barrel — Force Chamber, 5 ft. 4 in.; Suction Chamber, 5 ft. 4 in.; Suction Air Chamber, 4 ft. 6 in.; Discharge Chamber, 4 ft. 5 in.; Plunger Chamber, 5 ft. 5¾ in.
27. Metal in Pump Barrel; Cast Steel.
28. Diameter of Cage Plates; 5 ft. 5¼ in.
29. No. Valves each Suction Cage Plate; 247.
30. No. Valves each Discharge Cage Plate; 247.
31. Total number Valves each Pump; 1482.
32. Total Area of Valves each Suction Cage Plate; 1368 sq.in.
33. Total Area of Valves each Discharge Cage Plate; 1368 sq.in.
34. Diameter Valves; 3¾ in.
35. Proportion Valve Area to Plunger Area; 164%.
36. Material in Valves, Seats, Stems and Springs; Rubber, Gun Metal, Bronze, Brass.
37. Lift of Valves; ⅝ in.
38. Diameter of Plungers; 32⅝ in.
39. Speed of Plunger; 220 ft. per min.
40. Total Displacement per Revolution; 716.5 gal.
41. Number of plunger or distance rods; Four to each plunger.
42. Diameter of plunger rods; 5 in.
43. Diameter of discharge pipe; 36 in.
44. Diameter of suction pipe; 42 in.
45. Cooling surface of condenser; 1800 sq.ft.
46. Number of tubes in the condenser; 701.
47. Size of tubes; 1 in. o.d.
48. Metal in tubes; Brass.
49. Size of air pump; 24x66 in.
50. Size of boiler feed pump; 3¼x66 in.
51. Size of air compressor; 3x66 in.
52. Total estimated weight; 875 tons.

The condenser is a water-works surface type with steam passing through the tubes. It is located in the suction pipe and all the water pumped passes through it. This arrangement might be criticized since it reduces the temperature of the condensate to very nearly that of the water pumped and gives cool boiler feed. It is proposed to install an exhaust feed-water heater on this engine to increase the B.t.u. duty. A method of bypassing only a part of the water pumped through the condenser is followed with some of the pumps of the Department but after considering all of the working conditions it was decided that the scheme adopted was the best.

Among the miscellaneous items of interest are the following: governor controlling the cutoff of the high-pressure cylinder with hand-controlled cutoff on the intermediate and low-pressure cylinders; a sight-feed force lubricator from which feed connections are made to all rotary valve stems, the throttle and intermediate-cylinder side pipes; a central oiling system with filters and oil tanks; a two-stage air compressor for supplying air to the air chambers. Further details of the pumping engine are summarized in Table 1, which shows the data required of the contractor with his bid.

Table II gives the data which was obtained from the test log sheets. The figures given are averages for 24 hr.

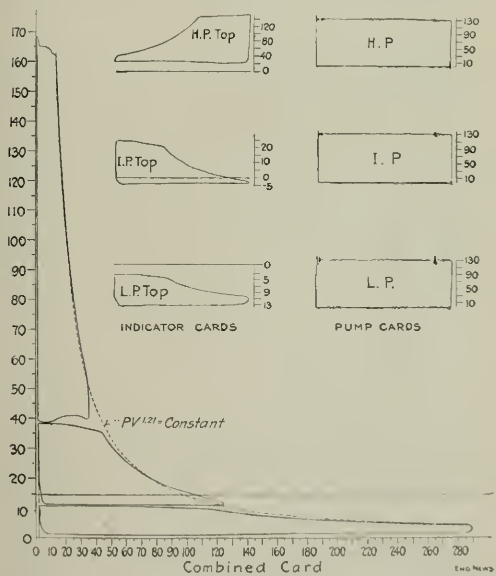

Fig. 3. Straight and Combined Steam-Cylinder Cards and Pump Diagrams; New Bissell's Point Engine

Table III gives the results as calculated from the data given in Table II. The discharge pressure was measured by means of a mercury column. The specific gravity of the mercury when at 58.18° and compared with the water pumped, at the same temperature, was found to be 13.58. The weight of a cubic foot of water at this temperature was taken to be 62.38 lb.

TABLE II. TEST LOG DATA, ST. LOUIS 20,000,000-GAL. HOLLEY PUMPING ENGINE

1. Steam Pressure, 159.41 lb. per sq. in.

6. Reading of Pressure Mercury Column, 301.5 ft.
7. [illegible]
8. Average Temperature of Mercury Column, 76.1°
9. Elevation Water in Wet Well, 95.31
10. Diameter H. P. Plunger, 32.82 in.
11. Diameter [illegible] Plunger, 32.818 in.
12. Diameter L. P. Plunger, 32.81 in.
13. Stroke of H. P. Plunger while running, 65.875 in.
14. Stroke of [illegible] Plunger while running, 65.828 in.
15. Stroke of L. P. Plunger while running, 65.806 in.
16. Water Pumped in 24 Hours (actual plunger displacement), 20,576,500 gal.
17. Water Pumped in 24 Hours (Venturi meter readings), 20,600,000 gal.
18. Weight of Condensate, 230,165 lb.
19. Weight of First Receiver Drain, 1883 lb.
20. Weight of Second Receiver Drain, 8209 lb.
21. Weight of Jacket Drain, 11,763 lb.
22. Total weight of steam, 252,020 lb.
23. Weight of steam per hour, 10,503.7 lb.
24. Temperature of water pumped, 58.45°
25. Temperature of Condensate, 61.73°
26. Temperature of First Receiver Drains, 263.101°
27. Temperature of Second Receiver Drains, 197.705°
28. Temperature of Jacket Drain, 164.27
29. Plunger leakage per hour, 333 lb. (Specification allowed 100 gal.)

Fig. 3 shows a set of indicator cards. This set was taken at a time when all of the conditions were as near as possible to those of the specifications. All indicator cards both steam and pump ends, were taken every hour and were taken simultaneously by electric control. Fig. 3 also shows a combined card made from the set of ordinary cards after they were corrected for the spring calibration. The curve $pv^{1.21}$ = *constant* is the nearest pv^n = *constant* curve to that shown by the indicator cards*.

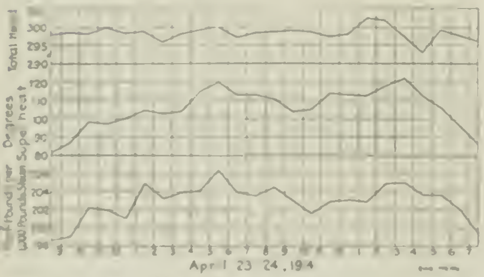

FIG. 4. HEAD, DUTY AND SUPERHEAT CHARTS FOR TOTAL RUN OF BISSELL'S POINT ENGINE

Fig. 3 shows also the set of pump cards corresponding in time to the other cards. Fig. 4 is a chart showing the relation between duty, superheat and total head pumped against for the test run. The duties were figured hourly and do not take into account the small correction due to the temperature of the mercury column. The maximum duty, after making all corrections, of 202,105,616 ft.-lb. per 1000 lb. of steam at 160 lb. pressure and 100° superheat, is the highest of which the writer has any knowledge.

The test was conducted for the City of St. Louis by L. A. Day, Chief Mechanical Engineer of the Water Department and the writer. The Holly Co., represented by D. A. Decrow, Chief Engineer, and H. E. Gibbs, who prepared the pump for testing. There were 25 observers taking readings during the test.

*[illegible]

TABLE III. AVERAGE TEST RESULTS, ST. LOUIS 20,000,000-GAL. HOLLEY PUMPING ENGINE

1. Absolute steam pressure, 174.03 lb. per sq. in.
2. Superheat (corrected emergent stem thermometer), 105.23
3. Average value of superheat in duty, 10° equals 1,000,000 ft.-lb.
4. Pressure by mercury column (corrected for temperature), 301.13 ft.
5. Total head pumped against (95.31 — 92 + 3.31; 301.013 + 3.31 = 297.703), 297.703
6. Gallons per revolution, 714.137
7. Weight water pumped per revolution, 5957.7 lb.
8. Average revolutions per hour, 1200
9. Duty, foot-pounds per 1000 lb. steam without correction for excess in superheat,

$$\frac{1200 \times 5957.7 \times 297.703}{10,503.7} = 202,625,616$$

10. Deduct for 5.23° of superheat, net duty, 202,105,616 ft.-lb. per 1000 lb.
11. Heat per pound superheated steam, 1256 B.t.u.
12. Total heat delivered to engine, 316,625,[illegible] B.t.u.
13. Heat per pound condensate, 29.87 B.t.u.
14. Total heat in Condensate, (13) × (18), 6,874,431 B.t.u.
15. Heat in one pound of First Receiver Drains, 231.8 B.t.u.
16. Total heat in First Receiver Drains, (15) × (19), [illegible] B.t.u.
17. Heat per pound Second Receiver Drains, 167.63 B.t.u.
18. Total heat Second Receiver Drains (17) × (20), 1,374,563 B.t.u.
19. Heat per pound jacket drains, 132.15 B.t.u.
20. Total heat Jacket drains (19) × (21), 1,554,[illegible] B.t.u.
21. Total heat rejected, 10,240,071 B.t.u.
22. Heat consumed by engine, 306,384,969
23. Total foot-pounds work done in 24 hr., 51,[illegible],697.[illegible]
24. Duty, foot-pounds of work per million B.t.u. consumed by engine,

$$\frac{24 \times 1200 \times 5957.7 \times 297.703}{306,384,969} = 166,719,796$$

25. Water horsepower developed, 1074.91
26. Steam per water horsepower-hour, 9.77

The Remarkable Success of Typhoid Vaccination in France and the French colonies was brought before the engineers of the Ponts et Chaussées of France by Prof. H. Vincent of French Academy of Medicine, in a paper published in the Annales des Ponts et Chaussées, May-June, 1914. Prof. Vincent described in detail the nature of the vaccination and its effect on the individual and presented finally a table showing the comparative morbidity and mortality records in a number of small epidemics and particularly among the French army resident in northern Africa. These figures in the original are given for each town and city camp and state the number of non-vaccinated and vaccinated persons with the number of cases of typhoid and deaths from typhoid in each class.

A compilation of the figures shows that in [illegible] nonvaccinated persons the average typhoid rate was 63 per thousand, whereas in 15,[illegible] persons subjected to the same conditions but vaccinated against typhoid, the morbidity rate was practically nothing, there being reported only two cases. In the non-vaccinated class the typhoid rate was as high as 195 per thousand in the epidemic at Avignon (July, 1912) and 168 per thousand in the army camps in western Morocco in 1914.

The Fuel-Briquetting Industry in the United States in 1913 was characterized by a net decrease of two in the number of operating plants and a decrease of 17% in quantity but an increase of [illegible] in the value of the manufactured product. The United States Geological Survey explains this condition by stating that briquetted fuel in the United States is essentially a domestic fuel for which there was less demand in 1913 owing to the mildness of the winter. The explanation for the higher values in the face of decreased demand appears to be in the general enhancement of values of all industrial products in that year. In the production of briquets, seven plants used anthracite culm or fines, one used semi-anthracite, one used anthracite and bituminous slack, mixed in proportions of 1 to 1, one used anthracite culm and bituminous slack, principally the former, five used bituminous or semi-bituminous slack, and two used carbon residue from gas works making gas from petroleum; eight plants used coal-tar pitch for binder, one asphaltic pitch, [illegible] and five mixed binders of [illegible] and [illegible].

The total production amounted to 181,[illegible] short tons valued at $1,[illegible] compared with 22[illegible],[illegible] tons valued at $[illegible] in 1912. The production for the four years preceding 1912 was as follows: 1907, 66,[illegible] tons; 1908, [illegible] tons; 1909, [illegible]; 1911, [illegible].

Editorials

Columbus' noted egg-balancing feat finds a sort of parallel in a modern pile test, where the engineer sets a 40- or 60-ton load on the top of a slender pile of doubtful verticality and straightness, and expects it to stay put while he measures the settlement of the pile. A correspondent recommends guying such loads; yet the Pittsbugh tests and the Panama-Pacific Exposition tests (in our issue of July 30, 1914) were successful without guying.

The prominent fact of the matter is that pile testing has hitherto been thought very unimportant, so that descriptions or discussions of proper methods of pile testing are scarce as snowflakes in June. The same is true of soil-loading tests. Both kinds of test give highly valuable information, and (in our view) are destined to find wide use in the future. At the same time, both tests may prove to be either inexpensive or very costly, depending on the way the test is arranged. And, what is even more important, the information furnished by the test may be instructive or seriously misleading, again depending on the test method. There is room for fuller study of the subject.

⁂

Detroit has foundation problems quite peculiar to itself. Many different solutions are to be found among the structures erected in that city, each one being found of interest. Among them not the least is the remarkable foundation of the new Michigan Central terminal and office building. We believe it is little exaggeration to class this foundation among the notable examples of building-foundation work of the last half dozen years.

No other 18-story steel-frame building of modern times rests by means of a very thin shell of reinforced-concrete directly on deep clay soil of uncertain and variable character.

A discussion of the problem presented in the case, and of the solution adopted, is of course outside of the editor's sphere, and may be safely left to the members of the profession competent for it. But to supplement our descriptive article, we should note that in the course of the design, one expedient was recommended which later was not embodied in the structure, and commentators may well consider its bearing on the case. This was a line of sheeting, which was to be driven around the edge of the reinforced-concrete mat, some 15 or 20 ft. into the soil below, to act as a confining curb, a protection against possible localized outward flow of the clay under the foundation pressure. This expedient was recommended by a highly conservative and competent engineer, but was finally overruled. As built, the foundation subsoil has no restraint to outward flow, and no such flow is expected.

⁂

It is alarming to learn that under traffic conditions which exist in many parts of the country standard practice in designing highway bridges is inadequate (this means *unsafe*) for short spans—spans up to 50 or 60 ft. Bridges have been designed to carry road rollers (and only one roller at a time), while the actual traffic requires them to carry much heavier motor trucks, and two of these will often pass each other on a bridge. Further, when a truck going at a speed of 6 to 10 miles an hour bumps along over a rough bridge-floor, there is a respectable amount of impact, although talk about highway-bridge impact has hitherto been regarded as highly academic, not to say hairsplitting.

It may be thought that the statements and conclusions given by Manville and Gastmeyer on another page of this issue are overdrawn and needlessly disquieting. But the engineers of Cuyahoga County, Ohio, recently took action along exactly the same line of thought; they carefully reviewed all bridges under their charge to learn how they are stressed under motor loads, so that those bridges which cannot safely carry modern freight-truck traffic may be known, and warning notices posted to limit their loading.

The fact is that commercial motor trucks have grown amazingly in number, and at the same time heavier and heavier capacities and axle-concentrations have been employed. This has progressed to a point where the safety of road bridges is menaced. The truck builders are not to be blamed, for they merely followed the demands put forward by truck users; they went about their own business in the tacit belief that bridges as well as roads could carry anything that might cross them.

Bridge engineers are notoriously conservative. They design only for existing loads, rarely looking toward a speculative morrow. The Pennsylvania Highway Commission some time ago established a 24-ton truck as standard for designing bridges on main roads near cities; in New Jersey a 20-ton truck is assumed; and possibly some other authorities are equally progressive. But in the main the growth of street and road loadings has left highway bridge practice in the rear. It is necessary to revise the current standards.

The immediate need, however, is to study existing road bridges, decide what loads may be allowed to pass over them, and post notices stating the limit of allowable load. This duty rests in part on the states, but in larger part on the counties, who are the real road authorities. Public safety requires them to act.

⁂

Preserving Concrete Linings On Fresh Canal Banks

The difficulties in placing concrete on newly made slopes in such a way that it will hold its form and alignment, are so frequently noted that instances of conspicuous success are of unusual interest. Therefore attention is directed to the description, elsewhere in this issue, of the work on lined canals for the Seros power project near Barcelona, Spain. Here are to be seen some 17 miles of relatively deep canals connecting the diversion works, regulating reservoirs and penstocks. Attempts

to spread an impervious lining on the slope of $1\frac{1}{2}$ on 1 were futile and forms had to be used. Only three-fifths of the height of bank was lined at first, the work being completed after water had been in and the initial settlement obtained. In testing out this construction, any serious displacement of the lining was anticipated by watching for the development of cracks between concrete and earth at the top of the bank and forcing a clay puddle into the dangerous spots to maintain continuous support. Only something like $3\frac{1}{2}$% of the canal banks required any treatment.

It is also interesting to note that similar means was successful in sealing incipient settlement cracks of the seven earth dams on this project (to be described in a subsequent issue), so that the combined leakage, including that through the rock strata of the hillsides was under 3 sec.-ft., or 7/100% of the normal flow from storage.

The Next Convention of the New England Water Works Association

The New England Water Works Association, which will meet in annual convention at Boston next week, occupies a unique position. By establishing a non-resident membership, publishing an excellent quarterly journal, and later on by holding some of its annual conventions outside of New England, this organization with a local name has achieved high rank among the national technical societies of America.

While being a national society, the New England Water Works Association has served admirably not only the geographical section indicated by its name, but also the more local needs of the Boston metropolitan district. The sectional and local needs have been met by the maintenance of rooms and a library in conjunction with the Boston Society of Civil Engineers and by its monthly luncheons, which keep up social relations and afford a never-neglected opportunity for the presentation of papers and for informal discussions of the problems of the water-works superintendent and engineer. The rooms, library and monthly meetings are, of course, open to all non-resident members [illegible] avail themselves of the privilege, and the monthly meetings go far in providing live material for the *Journal*, which through several decades has been a [illegible] binding all the members together, regardless of geographical location and all other [illegible] conditions.

For a few years the New England Water Works Association equaled, if it did not exceed, the American Water Works Association in membership, as it had long surpassed it in usefulness to the water-works profession. Recently the American Association has forged ahead in membership, got out from under various clouds, started a quarterly *Journal*, made possible the formation of sections throughout the country, and established a New York section. The American Association is not yet in position to have permanent headquarters, but there is reason to hope that this may be possible within a few years.

Although we have no reason to think that the officers of the New England Water Works Association are [illegible] in their aims lest their organization be forced back into New England territory and there cramped and confined by the American Association, we have no doubt but that the New England officials are awake to the friendly rivalry that exists. One of the claims made in behalf of the American Association is that it surpasses the New England Association in usefulness to superintendents. Unless we are greatly mistaken, a careful analysis would show that most of the papers and notable committee work in each association have been contributed by engineers rather by superintendents.

However all this may have been in the past, the program of the New England Water Works Association for its convention to be held at Boston, on Sept. 9 to 11, devotes several sessions exclusively to superintendents. This is a desirable thing to do. The superintendents make up a high percentage of the membership of all the water-works associations. Water-works are constructed in relatively brief time, but have to be operated 365 days and nights in the year. Strangely enough, relatively few papers dealing with strictly operating problems are presented, and there are practically no books on water-works operation in existence. It is sincerely to be hoped that the superintendents' sessions at the Boston convention next week will be fully attended and the papers extensively discussed.

How May I Become an Engineer?

Although not so specifically put, the above title is the question a correspondent is asking when he writes:

> Some time ago there appeared in your magazine an editorial urging young men who have an engineering education and who are willing to "rough it," to go out West and, starting out as county surveyors or in any other capacity in the employ of some municipality, endeavor to build up a general engineering practice. Will you kindly suggest a way in which a young engineer hesitating to spend a good deal of his ready money in order to get to a part of the country, which is to him as yet shrouded in a haze of mystery, and there wait until he is lucky enough "to strike a job," may get in communication with someone who could give him more definite information before he ventures out of his home city? I believe that a suggestion of this kind would be welcomed by a good many young engineers.

First let us correct an erroneous conclusion our young friend has evidently drawn from our editorial, "A Neglected Opportunity of the Engineering Graduate" (Engineering News, Dec. 11, 1913, p. 1196), in which we pointed out, from very good evidence on another page of the same issue, that many county surveyors and county engineers in some of the Middle Western States are incompetent and ignorant, and that young engineering graduates were neglecting their opportunities in not getting in line for those offices.

We did not then, and, so far as we know, never have urged young men to go West and ask for positions as county surveyors and engineers. County engineer jobs are not to be had that way; unfortunately, as we have said before, many are too much mixed with politics. Neither have we [illegible] advice or suggestions to offer our young friend as to how to secure those positions, since there are other things he will have to learn first. But we will undertake to offer for his perusal, and by chance the perusal of the "many other young engineers" referred to, a few truths that it is time he and they knew.

First, this is a tough year for the new engineering graduate. Jobs in engineering work are few and hard to

get. Second, there are a great many engineering college graduates; an estimate of 5000 per annum is conservative, from what might be termed first-class technical schools and universities. More than that, according to the United States Immigration statistics for the fiscal year ending June 30, 1912, some 1500 admitted aliens were professional engineers, who are for the most part in this country now, although present European conditions will restrict such immigration for a few years to come. Hence from the nature of things, competition for work in the lower ranks of engineering is keen.

Another point to be remembered is that graduation from a technical school doesn't make an engineer. If the institution from which our correspondent has just been graduated has granted him the degree of Civil Engineer, why so much the worse for our young friend if it has aroused in him visions of his glad welcome into the ranks of real engineers. All other things being equal, his chance of becoming a civil engineer is better than that of a fellow who has not had the advantages of a technical education; but that is all that can be said.

He would like to know how to begin as an engineer; he needs to know the prime requisites of an engineer. First and foremost, and the one that is most frequently neglected and overlooked, is a natural inclination, or an inherited or otherwise acquired predilection for mathematics and the natural sciences. The natural inclination must be more than a desire for an outdoor life and the pleasure of tramping through green fields and shady woods. Secondly, and hardly less to be considered, are self-confidence and self-reliance. There never was a successful engineer without these, however modest and unassuming in outward demeanor. A third and by no means the least prime requisite is industry—a real love and enthusiasm for engineering work as such, and a genuine joy and innate pride in results accomplished.

As to the first of these requisites, we do not know how our correspondent stands; he alone is judge of that; but we do know that our technical schools and universities are turning out annually many bright young men who have taken engineering courses solely from having been misled by extravagant and utterly untrue pictures of the lives and prosperity of the rank and file of civil engineers. Many an engineering graduate comes to a realization of his special fitness for some other work before he has been out very long. He seldom has cause to regret his technical education, if it were really an education and not the memorizing of a conglomeration of facts and formulas.

On the second essential requisite, we should judge our correspondent needs enlightenment. If a young man is able-bodied and not afraid of manual work, and is free from family responsibilities, he certainly should not be afraid of starving, even if he has not had the advantage of nearly 20 years of schooling, as most technical graduates have.

There is not a contractor, railway or other corporation, or individual, who would not employ an able-bodied American college man in preference to a foreign "roughneck," if the college man were willing to roll up his sleeves and get to work. Such a job isn't inviting, but it offers experience that can be gained in no other way; it offers an opportunity to get into contact with construction work and with engineers, and without these no man ever yet progressed very far as an engineer.

This year, jobs are not coming to the engineering graduate; owing to the tremendous outflux of engineering graduates, it is doubtful if that time ever comes again. In England, young graduates pay a premium for the chance to work at engineering. Some of our graduates might prefer this method, but they are not the stuff of which American engineers have been made. More than one railway officer and chief engineer has started his career as a sectionhand; college men have not infrequently started in this way, and doubtless every one of them who has afterward attained success feels very proud of his early experience, as he has a right to do.

If one lacks self-reliance, there is no better way of curing this failing than to prove to himself that he can earn his bread and butter by the sweat of his brow. This isn't an idle fancy or a theoretical discussion; it is based on personal experience, and the experience of many another man. We sympathize with our young friend, but if a fellow hesitates to leave home and free board for fear of not being able to earn his living, he would better have stayed at home always than have gone to an engineering school.

As to industry, it is hardly worth while to elaborate, since every man ought to know that it is the only key to success in any line of work. Not all men who are industrious are successful, by a long shot. Yet it is safe to say no man was ever very successful as an engineer who wasn't industrious. Of course, one soon learns that opportunity cuts a big figure; or will we say just pure dumb luck? But luck in the game never comes to one who doesn't join in the game. This is just as true in engineering work as in almost any other.

Engineers and contractors, as Col. H. G. Prouty says, are the stuff that soldiers were made of; in the field, they are generally a rough and ready lot, used to forming quick judgments and making quick decisions. "He who hesitates is lost," is just as true of the engineer as of the soldier in the field of battle. No one of these men is going to think the worse of a young man for having served as a laborer or in any capacity that meant real serviceable work. There are no social distinctions in a construction camp, and an extra-bright laborer stands a far better chance of winning the respect, friendship and assistance of his employers, and of the engineers he comes in contact with, than an unknown "tenderfoot" who wants to be guaranteed a good position before leaving home and father's dining table.

We don't say "Go West, young man." If a recent item in a Western contemporary be correct, no less than 2000 applications for positions have been received for work on the proposed Hetch Hetchy Reservoir of the city of San Francisco. Evidently, the West offers no more and no better opportunities than the East, except that in the West there is a more democratic attitude toward work in general.

However, there are opportunities in both the East and West for men who are strong enough in body and purpose to handle a pick and shovel, run a dinky, a steam shovel, a concrete mixer, work with a hammer and saw, and a thousand and one other jobs, which the average engineering graduate turns up his nose at. These jobs are not inviting, truly, but they offer a means of earning a livelihood and they offer one way to enter the ranks of engineers; a way that many a bright, clever and ambitious fellow has made use of before now.

Letters to the Editor

Balancing the Load in a Pile Test

Sir—In your issue of Aug. 6, 1914, you describe load tests on concrete piles at North Side Point Bridge approach, Pittsburgh. From the sketch accompanying this article it would appear extremely difficult if not physically impossible to maintain such a large water tank in absolute balance over the pile. Would it not be more satisfactory to make such a test by supporting a tank on a platform on top of the pile and attaching to the sides of the tank horizontal guys, which would not affect the vertical action of the load?

T. L. Condron.

Monadnock Block, Chicago, Aug. 20, 1914.

Use of Current Meters in Large Pipes

Sir—In the June 11, 1914, issue, you published an article by K. A. Heron entitled, "Current Meters for Measuring the Flow in Large Pipes." Reference is made to experiments at the Minnequa steel plant of The Colorado Fuel & Iron Co., where both meters described "have been in use for several years." The statement is made that "the experiments were conducted and the meters designed by A. A. Weiland and the writer under R. M. Hosea, Chief Engineer of The Colorado Fuel & Iron Co."

Your attention is called to the *Journal* of the Western Society of Engineers, Chicago, May 17, 1911, and Engineering News, May 25, 1911, where is a paper, "Measuring the Flow of Water in large Pipe Lines," in which the record of experiments and the work referred to by Mr. Heron is authoritatively given. The meter illustrated by him in Fig. 1, was designed and constructed by J. S. J. Laille (deceased), mathematical instrument maker, Denver, Colo., early in 1908, in response to a request for a meter that could be inserted into a pipe line through a 4-in. gate valve, quite a time prior to Mr. Heron's employment by this office. The meter illustrated in Fig. 2 was first constructed in the shops of the Colorado Fuel & Iron Co., Pueblo, Colo., in 1908 and 1909 from plans made in this office, drawn by R. G. Hosea, and embodying his ideas and those of A. A. Weiland, H. A. [illegible] and other engineers and employees of the company. This was also prior to Mr. Heron's employment, except as [illegible].

The meter giving satisfactory results, an improved [illegible] was prepared and submitted to W. & L. E. Gurley with the request for such additions and improvement as their wide experience might suggest. The mechanism for [illegible] the counter was shown in Gurley's *The* [illegible] and the meter as constructed by W. & L. E. Gurley and put into practical form in a [illegible] manner, as shown in the writer's paper before the Western Society. Mr. Heron worked under direction on [illegible] for this improved device in this office in 1909, for a time. Before and after this date he was regularly employed as concrete inspector until leaving the service in June, 1910. Mr. Weiland was engaged in water-investigation work with the writer in 1908 and 1909, but left the service of the Colorado Fuel & Iron Co., Feb. 15, 1910, before the improved meter was built or used.

Some work was done with the pitometer in our pipe lines, by Mr. Weiland, and he made the suggestion of inserting an electrical meter in a closed pipe in the same manner as the pitometer (as shown in E. S. Cole's article "The Pitometer & Water Works Losses," in the 1906 *Proceedings* of the American Water Works Association). The putting into practical form was, however, done by Mr. Laille and others and Mr. Heron had nothing to do with it. He was probably not familiar with the facts when he prepared his article. For the reasons given in Engineering News, May 25, 1911 (and in the present letter), the design was given publicity.

The foregoing gives the bare statement of facts which the writer believes he is in a better position to do than Mr. Heron. In fairness to all concerned, I request publication of this letter.

R. M. Hosea,

Chief Engineer, The Colorado Fuel & Iron Co.

Pueblo, Colo., July 3, 1914.

[Mr. Heron has offered the following comments:]

Sir—As suggested by Mr. Hosea, I was not aware that a description of the meters had been previously published. The publications mentioned are not available at the moment, but if Mr. Hosea's description was in the same manner as is his letter it is not too late to extend the credit he has given for this work. He has [illegible] relegated me to a "thinking part," and then [illegible] Mr. Weiland's leaving the service of the company "before the improved meter was built or used."

I was connected with the Colorado Fuel & Iron Co. for the greater part of four years, and most of this time was spent in the Water Department of the company on various engineering work. From three years' close association with Mr. Weiland, and with an intimate knowledge of the operations of the water department, I have always understood that this electrical meter was developed solely by him, and was made by Mr. Laille in the manner suggested by Mr. Weiland, who was in charge of water investigations for the company in 1908-09-10. I assisted Mr. Weiland in the rating of this instrument and in a number of experiments during the summer of 1909.

In the early part of 1910, Mr. Weiland left the service of the company. I had been associated with him for a time, and shortly before he left we started the preparation of plans of what was then the improved meter. The meter as constructed by W. & L. E. Gurley was according to a set of plans that were prepared in their entirety by me (under the general direction of Mr. Hosea), applying the [illegible] experience in this line of Mr. Weiland. As Chief Engineer of the company, Mr. Hosea

was responsible for all the work of the engineering department, and may choose without question whatever credit he desires for his work.

Mr. Hosea seems to think that I am claiming too much credit for the part I took in this work when, as a matter of fact, I was merely describing an interesting method of water measurement in the development of which I had assisted.

K. A. HERON.

Modesto, Calif., July 16, 1914.

Opportunities for Engineers in the Argentine; A Warning

SIR—After reading the editorial in ENGINEERING NEWS, Aug. 20, p. 407, on the opportunities offered by the present European war to American commerce and engineering in South America, it has seemed advisable that a note of warning in regard to conditions of employment be sounded for some of your readers who may have drawn false conclusions from your remarks.

A young structural draftsman recently informed the writer that he had been devoting special attention to skewed work for the reason that the people of the Latin-American countries are swayed by their artistic natures to such an extent that their architects design very complicated roofs, domes, cupolas, etc., on all their buildings; and, since not many draftsmen are skilled in detailing such work, it follows that there must exist a demand for those with the necessary qualifications.

Granting without question the great amount of queer roofs to be seen in South America, the conclusions drawn are quite wrong. It must be remembered that industrial work in South America and in Europe is regulated by very different customs from our own.

The functions of the American engineering draftsman are carried out by two types of men. The first is merely a mechanical copyist, who makes tracings or show drawings from the sketches of engineers. His pay in the Argentine is about \$65 per month, which, considering the high cost of living, is about equivalent to \$50 in this country. He works slowly, but with skill, and produces drawings beautifully lettered and elaborately finished, often in colors.

The second type is that of the German "techniker," somewhat similar to the "designing" or "engineer draftsman" of our better railway bridge drafting rooms. He is competent to and does design simple structures and prepares the detailed pencil drawings for the tracers. His pay is about \$130, or, say equivalent to \$100, and is very seldom increased.

A "techniker" is a graduate of a "technikum" or school offering two-year courses in specialized branches of engineering. Its graduates are often men of much practical experience, who have wished to study some of the theory underlying their work, and they rank considerably above the average American structural draftsman.

There are many such men in South America, but frequently their place is filled by young Italian, German, Austrian or Scandinavian civil-engineer graduates of the great European universities, who are willing to work for small salaries while learning the language of the country or while "revalidating"* their degrees.

The cost of living is particularly high in Buenos Aires, where American shoes cost \$8 to \$10 per pair, Stetson hats \$10 each, collars \$2 per half dozen, etc. A small and uncomfortable room with meager board in the native style will cost \$50 to \$75 per month. In spite of these excessive expenses, many young Europeans have flocked to Brazil, Uruguay and the Argentine. Often these men have enjoyed excellent educational advantages; yet they are used to much lower salaries and more modest conditions of living than our young men, and hence are willing to work for the small wages mentioned.

Only a few of the foreigners have been able to leave South America to return to their countries since the sea has been closed to merchant steamers. Great numbers will pour into the southern countries at the close of the war. It should be perfectly evident that our draftsmen, clerks and high-grade artisans, with all the national ignorance of and disinclination to learn foreign languages, will be able to offer very little real competition to these men.

The case is not very different for engineering graduates. In the Argentine, for example, as I have shown in my letter in ENGINEERING NEWS, Apr. 30, 1914, p. 979, the cost of "revalidation" is so high, the time so long and the requisite knowledge of Spanish so unusual, that no private practice could ever be obtained. As employees of American companies, engineers are apt to become much dissatisfied with living conditions, unless the salaries paid are very high.

It should, of course, go without saying that it is useless to expect any success in South America unless one speaks Spanish or Portuguese. A large part of the passenger list of every steamer to Rio or the Plate is made up of soi-disant engineers "looking for a job." Most of them return in a sadder and wiser frame of mind after a very short visit. The writer has even seen American mechanics who have journeyed all the way to Buenos Aires "on speculation." He is not speaking of the threshing machine operators who come on contract. When it is realized that in Buenos Aires a 10-hr. day's wage for brick masons is less than \$2.50, or for carpenters \$2, the utter folly of such "speculation" is seen.

To turn to the more general aspects of the case: South America has no floating capital of its own and does not usually borrow it directly to accomplish public works of great magnitude, preferring rather to grant long-time concessions to foreign capitalists, who naturally purchase all supplies in their own countries. Thus the great port of Rosario was built, and is operated, by a French syndicate. Most of the railways are English. Mineral enterprises are English and American. Many of the electric plants and most of the quebracho forests are German. The meat-packing industry is fast being controlled by Americans. Only in accordance with the amounts that American capitalists are able to invest in other enterprises will engineering work be carried out with American materials.

It is probable that England will keep the seas clear for her enormous commerce, which will continue with but temporary interruptions. With French wines, silks, objets d'art, etc., we do not compete. The opportunity, such as it is, presents itself to us to acquire the trade of Belgium and Germany in metals and manufactured goods. This may, perhaps, last only as long as the war. We are absorbing at present about all that is economically

*"Revalidating" engineering degrees here means practically the process of obtaining a license as Civil Engineer.

[illegible] of South American products, and the general principles of commerce will act to prevent us entirely and permanently supplanting those countries, for they can consume very much more of the South American exports than we.

Our opportunity is for establishing and extending the market for certain articles which we manufacture better, or more cheaply, than the European countries. Many of these are already in the field, and others, such as electrical supplies (in which our present trade is weak), cement, structural materials and small manufactured goods, could secure a decided foothold—only, however, in case our manufacturers will adopt the most modern methods of selling. Let the market be seriously studied as to its [illegible], demands and possibilities. Spanish-speaking representatives, who have some understanding of the customer's character, must be found. Unfortunately, these are few and far between.

What I have said applies mainly to the East Coast countries. On the West Coast, our commerce and enterprises have been developing for some years in a healthy manner. The opportunity for increases is good, but is strictly limited by a very much smaller population and purchasing power than in the princely East Coast republics.

This letter is written not in pessimism, for many opportunities do now exist for the wise and adaptable manufacturer, but as a warning against over-rashness on the part of adventuresome men, young or old.

Cyrus T. Brady, Jr.

615 Lake St., Elmira, N. Y., Aug. 24, 1914.

The Waterproofing of the Muskogee Reservoir

Sir: In one of your recent issues, there appeared a full-page advertisement dealing exclusively with the merits of a waterproofing material applied to the interior surface of a [illegible]-gal. reservoir designed by the writer for the City of Muskogee, Okla. The inference in the advertisement is plain that the waterproofing is wholly responsible for the excellent results secured.

The specifications covering the construction of this reservoir did not contemplate the use of any special waterproofing material. The only waterproofing called for was two coats of neat cement wash to be applied with a whitewash brush on the inside of the basin, the second coat to be applied before the first one had had time to get very hard. The writer is of the opinion that any special waterproofing for such a structure is unnecessary to secure the degree of water-tightness called for in the specifications under which the reservoir was constructed. However, as the contractor was under contract to keep the leakage within the limits of the specifications, he would be [illegible] the additional precaution, entirely at his own expense, of [illegible] a patent waterproofing ingredient in the cement wash called for under the specifications.

Under ordinary conditions the writer is opposed to the use of waterproofing ingredients in the concrete or waterproofing applications to the exposed surface. It is far better to put the value of waterproofing materials into the concrete work itself by adding more cement and [illegible] better workmanship. In general, the use of waterproofing ingredients or applications tends to poor construction work, the contractor counting upon the waterproofing to materially help out careless construction. At Muskogee, Okla., the faithful work done by the contractor in mixing and placing the concrete was ample assurance to the writer that the structure when completed would be water-tight within the limits of the specifications.

The writer has designed a number of reinforced-concrete reservoirs in which neither waterproofing ingredients nor applications were counted upon for water-tightness, and in many cases not only a water-tight but a practically damp-proof construction was obtained. That it is possible to obtain with concrete, water-tightness sufficient for all practical purposes is an established fact. In the past two years the writer has constructed four identical sewage pumping stations, three at Harrison, N. Y., and one at Moorestown, N. J., in which the pumping pits are constructed below the ground-water level and subjected to hydrostatic heads ranging from 7 to 10 ft. In three of these pumping stations, a satisfactory damp-proof construction was obtained. In the fourth case, the contractor had considerable trouble from leakage and sweating, which can only be attributed to poor workmanship, and which necessitated the use of a waterproofing application to meet the requirements of the specifications.

In addition to the Agency Hill Reservoir, the writer also designed and constructed for the City of Muskogee, a 6,000,000-gal. reinforced-concrete settling basin in which no waterproofing ingredients or applications were used. The water-tightness of this structure came well within the specifications, which were similar to those for the Agency Hill Reservoir.

Alexander Potter

Havana, Cuba, Aug. 20, 1914.

NOTES AND QUERIES

A Formula for Columns Subjected to Bending, given in our issue of Aug. 27, p. [illegible], by Prof. J. [illegible] contained a slight typographical error. In the final formula for [illegible], middle of second column, the denominator should have the figure 1 in place of the letter l. The corrected formula thus reads: [illegible]

A. M. V., [illegible], Chicago, Ill., [illegible] whether he can collect [illegible] [illegible]

Pulling Steel Sheet Piling [illegible] after the work is done is not always an easy matter. In some of the bridge foundation work for the Grand Trunk Pacific Ry. along the Fraser River, in British Columbia, the hoisting hook inserted in the hole in the pile would tear through the web, splitting pile to the top. In one case the metal above the hole [illegible] and developed such intense heat that the folds were welded together.

A Large Sewer Tunnel at St. Louis

A costly piece of sewer work which has been undertaken at St. Louis, Mo., and which involves the unusual feature of working under pressure, is the Mill Creek joint district sewer. Its purpose is to relieve the old Mill Creek sewer, which is now working far beyond its capacity. The new sewer will be at a low level, as shown by the profile, Fig. 1, with drop shafts from several sewers above it. It will take the storm flow of the old sewer by means of a drop shaft near Vandeventer Ave. It will be 20,000 ft. in length, of which 18,200 ft. will be in rock tunnel, with 1800 ft. at the outfall built in open cut. The flow capacity is 3300 cu.ft. per sec.

the method of payment in tax bills, which necessitates the financing of the entire cost by the contractor.

On account of congestion in the main valley, the sewer is laid out along the ridge on the south side. To the east of Theresa St. the territory is built up almost solidly, being in the old part of the city. Core borings with diamond drills were made at frequent intervals, in order to obtain a reliable knowledge of the depth and character of the rock. The tunnel will be driven from a number of shafts, the approximate location of which is shown on the plan.

The tunnel is of horseshoe section, 16½ ft. high and 16½ ft. wide at the springing line. The principal sections in tunnel and in open cut are shown in Fig. 2. For the tunnel, which will have 60 to 90 ft. of rock

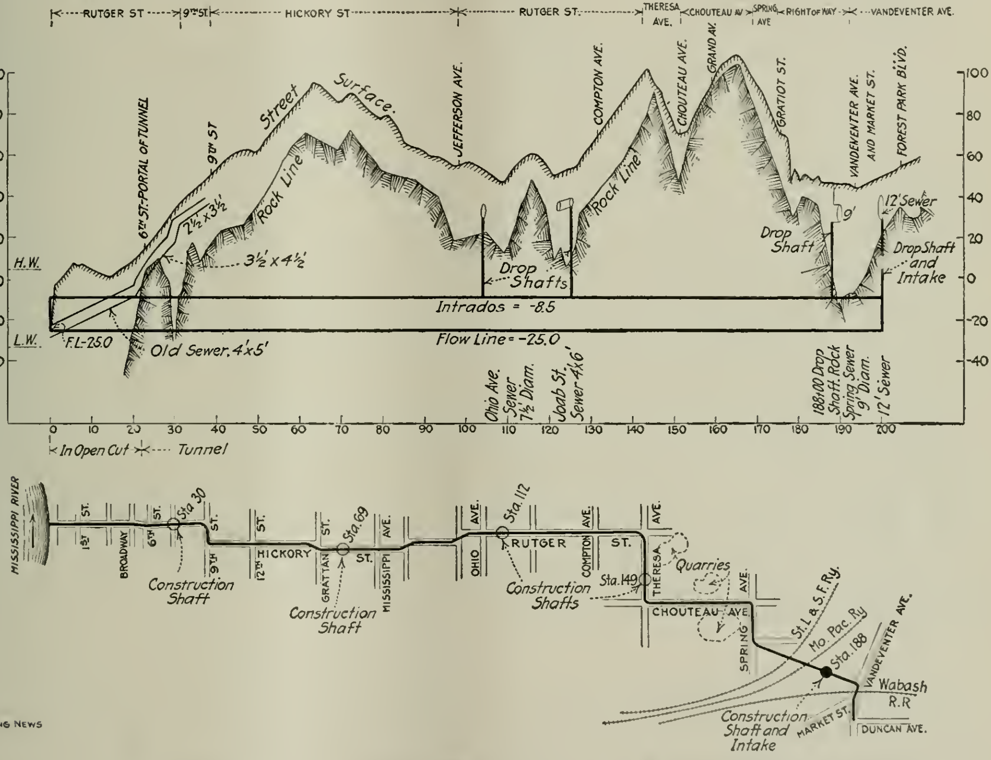

Fig. 1. Plan and Profile of the New Mill Creek Joint District Sewer, St. Louis, Mo.

The special features of the work include the following: (1) The design of a sewer as a pressure tunnel in order to construct the tunnel as far as possible through solid rock; (2) the consequent level flow line; (3) diversion chambers with peculiar overflow weirs in order to conduct storm water to the tunnel and ordinary sewage to the old Mill Creek sewer; (4) special drop shafts leading the flow from the diversion chambers in the high-level sewers into the tunnel; (5) the use of granite aggregate in the concrete work of the chambers and drop shafts; (6) the design of the reinforced-concrete section in open cut; (7) protection of the outlet by reinforced-concrete sheet-piling; and (8) most important of all,

cover, section (A) is to be used where the line of solid rock is more than 16 ft. above the springing, and section (B) where this line is 7 to 16 ft. above the springing on both sides. For open-cut work, with 25-ft. till, section (C) is to be used in rock, and section (D) in soft ground. These latter sections will have vitrified brick lining for the invert. The quantities are as follows:

	Tunnel		Open cut	
	Sec. A	Sec. B	Sec. C	Sec. D
Excavation, cu.yd.	11.74	13.39	5.89*	....
Concrete (within neat line), cu.yd.	2.88	4.53	2.61	4.91
Vitrified brick (cu.yd.)	.....	.....	0.21	0.21
Steel reinforcing bars, lin.ft.	.....	.....	112,500	298,000

*Excavation below springing.

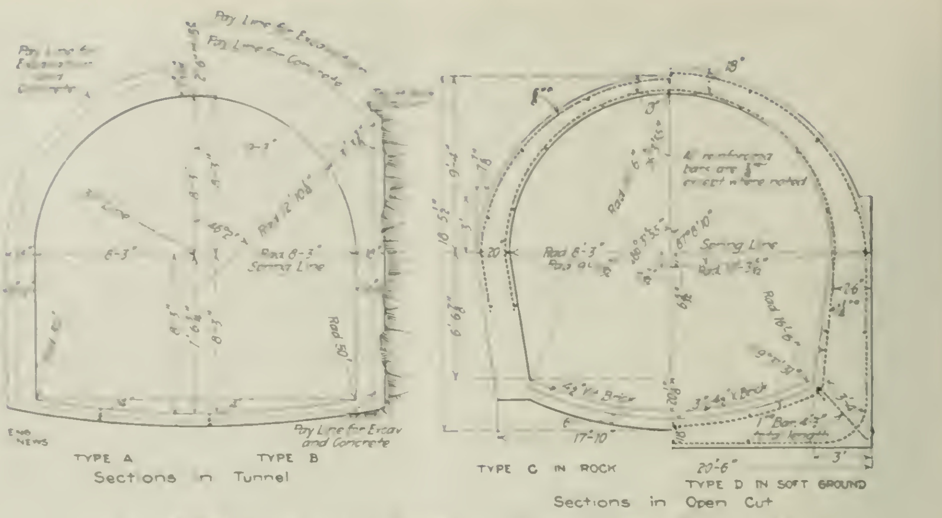

FIG. 2. CROSS-SECTIONS OF MILL CREEK JOINT DISTRICT SEWER, ST. LOUIS, MO.

In regard to the system of payment, which limits the work to contractors having strong financial backing, the notice to bidders stated as follows:

> Payment is to be made by special tax bills, divided into three parts, the first payment being due 30 days after the work is completed and service had on the property holders by the sheriff, the second payment in one year, and the third and last payment in two years from the time service is had on the property holders by the sheriff. All deferred payments will bear 6% interest. In case the property holder defaults on any payment, all becomes due and bears 8% interest.

The work was let out in two sections, one of 9500 ft. (including the outlet), and the other of 10,500 ft. Both were let to the Carter Co., of New York, as the lowest bidder. The contract prices were, respectively, $1,399,-[illegible] and $1,672,500, while the estimates were $1,500,000 and $1,700,000. The work is under the direction of J. A. Hooke, sewer commissioner. For plans and information we are indebted to W. W. Horner, principal assistant engineer of the Sewer Department, Board of Public Improvements.

Railways in Time of War

By H. Raynar Wilson*

The terrible war now raging on the European Continent has drawn attention to the important part played by railways in the mobilization and transport of troops, horses, guns, stores and commissariat. The importance of securing absolute possession of the lines and uninterrupted passages for the traffic was so great in England that the railways passed automatically into the possession of the State by an Order in Council made on Aug. 4, the day when war between Great Britain and Germany was declared. British railways are now under the control of an Executive Committee composed of the General Managers of some of the principal English Railways and of the leading Scottish [illegible]. Power to do this was obtained in 1871 by "The Regulation of Forces Act." This legislation allows the State to take possession of "any railroad [or tramway] in the United Kingdom and of the plant belonging thereto." Full compensation, as may be agreed between the parties for any loss or injury they may have sustained by the exercise of the powers is to be paid; in case of dispute the amount to be settled by arbitration.

On the European Continent the railways of Germany and Belgium are State-owned, and those of France, Austria and Russia that are not actually State-owned are practically so. In Germany there are, it is known, lines strategically laid out for military purposes, whilst in France the lines principally concerned, that is, the Northern and the Eastern, although privately owned, have always been recognized as of importance when the day arrived that found France again at war with her Eastern neighbor. It will also be remembered that it is claimed that military considerations contributed greatly to the plans of Bismarck for the State purchase of the railways of Prussia.

No railway in Great Britain has been constructed in which military considerations have entered; the only benefits that have weighed have been those of the public. There has, however, been a railway proposed that has secured not only the approval but the support of the military authorities. This was for a road known as the Outer London, which was to link up, on the outskirts of London, some of the southern and some of the northern lines. The proposals have been before Parliament on three occasions but, strange to relate, in view of the present terrible events, they have been rejected.

British railways enjoy several advantages in the matter of transportation of troops. There is, for instance, the short distance between the main centers. From Aberdeen, in the north of Scotland, to London, is 540 miles; from Edinburgh to London, 400 miles; Carlisle to London, 300 miles; Liverpool to London, 200 miles; Plymouth to London, 250 miles, and so on. Then, practically, all the lines are double-tracked—all those used for military purposes certainly are—and the main lines are [illegible]. Yet another benefit is that all are protected

*[illegible] Road, London, N. W. England.

by the absolute block system, but the stations being so close together, the permissive system can be readily adapted.

But the two chief advantages lie in the numerous alternative routes and the nearness of the stations to each other. There are, for instance, three routes, all direct, between London and Portsmouth, four between London and York, four between London and Liverpool, three between Liverpool and Hull. The benefit of the short distance between stations is that supposing troops are being sent from the area A to the port of E; they can be entrained at B, C, D, three stations in the neighborhood of A, and detrained at F, G, H, three stations in the vicinity of E. This, if trains are to be run at ten-minute intervals, would give half an hour for each train to load at B, C and D, respectively, and the same time at F, G, H, for unloading.

At the time of writing no details are available as to the movements of trains in Great Britain.

Before leaving this subject, it may be of interest to American readers to learn that Major-General Klein, an officer of high rank in the German army, strongly objects to the electrification of the main lines of Germany, because the destruction of a power house, or of the electrical supply, might seriously affect the rapid mobilization of troops. He also points out that Socialism was very strong in the ranks of electrical workers, which might be another adverse factor.

This warning was issued about 18 months ago, and in it the writer sees an explanation for the delay in opening electric traction through the Mount Cenis tunnel dividing France and Italy. Trains have been worked electrically on the Italian side between Bussoleno and the frontier town Bardonecchia for over a year. The writer, when visiting the works in June of this year, asked why they did not run through to Modane, in France, seeing that the installation was complete throughout. He was told that it was for international political reasons.

NEWS NOTES

Ohio Road Improvement Work is progressing with unprecedented speed. Before Jan. 1, 1915, it is expected to have approximately 900 miles of road under contract for improvement. [Ohio State Highway Department Monthly.]

A Headgate on the Welland Canal Was Carried Away at Lock No. 6, St. Catherine's, Ont., on Aug. 23, by the steamer "John K. Ketchem," owned by the Reid Wrecking Co. A footgate was also torn away, and the steamer dropped to the lower reach. The damage was small and traffic was not interrupted more than four hours.

A Gasoline-Tank Car Exploded near Savoie, La., on Aug. 28, killing four men and seriously injuring three others. The car was part of a freight of the New Orleans, Texas & Mexico R.R. Press dispatches state that the explosion followed the slipping of a chain attached to the car. It is thought that a spark might have been struck in this manner and ignited the gasoline.

Three Railway Bridges Burned—A bridge over the Ohio River ,at the foot of Sixth St., Cincinnati, Ohio, burned on Aug. 24. A bridge of the Wabash R.R. burned one mile east of Wilcox, Mo., on Aug. 16. The structure was about 200 ft. long and 30 ft. high. On Aug. 18, the pile approach to the little Pappio Bridge of the Union Pacific Ry., near Omaha, Neb., was destroyed by fire.

A Marine Collision between the "Admiral Sampson," of the Pacific-Alaska Navigation Co., and the Canadian Pacific steamer "Princess Victoria" resulted in the sinking of the "Admiral Sampson" off Point-No-Point, Wash., on Aug. 26. Press reports state that the steamer sank in four minutes, with a loss of 11 lives. It is alleged that neither vessel was making more than three knots an hour, in a heavy fog. The "Victoria" rammed the other vessel directly on a line with the after hatch, opening a 12-ft. gash in the hull, where fuel oil was stored, crushing several large containers. The oil caught fire. The "Victoria," which had kept her nose pressed into the hole, backed away as the flames enveloped both vessels. The lost vessel was of 2262 gross tonnage and 16 years old.

Improved Engineering Conditions in New York State—In the past two weeks the paper mill industry in northern New York has shown marked improvement owing to conditions arising from the European war. There seem to be several causes, such as the impossibility of securing foreign sulphite pulp much of which has come from Germany and Scandinavia, the uncertainty of obtaining material for ground-wood pulp from Canada as rapidly as usual, and the increased demand for extra editions of newspapers. This particular commercial improvement has materially brightened the prospects of engineering work generally in this locality where a large amount of civil and mechanical design has been held in abeyance.

Rules for Storing Gasoline in New York State were recently formulated by Fire Marshal Ahearn, as follows:

On and after Dec. 1 all existing buildings or other structures used as garages, with a capacity for housing more than four vehicles, shall immediately comply with the orders of the State Fire Marshal.

Repair shops shall not be maintained within a garage.

Torches, forges, fire or flame, or any electrical apparatus capable of emitting an exposed spark shall not be used or maintained in a garage or motor-vehicle shop. Heating shall be by steam or hot water.

No person shall conduct or maintain a garage, or keep or store any volatile inflammable liquid in connection therewith without a license or permit being obtained therefor, in accordance with the provisions of the State Fire Marshal law.

Gasoline or naphtha tanks will not be allowed under sidewalks. For those already installed reasonable time will be given to have them removed and reinstalled in compliance with the orders of the department.

Gasoline or naphtha tanks must be buried at least 3 ft. from the surface of the ground and proper piping connected to garage or curb outlet.

Smoking is at all times prohibited in garages.

No pits will hereafter be allowed.

No building or parts thereof shall be converted into a garage or used as such unless of fireproof construction.

Sand-Lime Brick Produced in the United States in 1913 was valued at $1,238,325, and represented the work of 68 firms. The value of sand-lime brick marketed and the number of operating plants which reported to the U. S. Geological Survey rose rapidly until 1907. In 1908 there was a decrease, in common with other industries. In 1909 and 1910 there were slight increases; in 1911 the lowest value ($897,664) was reached since 1904. In 1912 and 1913 there were gains, the total for 1913 being the maximum, though the number of active firms reporting was three less than in 1912. Last year the number of bricks manufactured was 189,659 M. The average price per M. for common sand-lime brick was $6.27 in 1913, as compared to $6.46 in 1912, and $6.09 in 1911; for front brick it was $10.61 in 1913, as against $10.41 in 1912, and $9.53 in 1911.

Michigan has been the leading state in number of plants and in value of production of sand-lime brick since the beginning of the industry in this country, with the exception of 1906. Twelve plants reported for 1913. The second state in number of operators was New York, which reported five.

Building Troubles in Russia—From a recent number of "Le Genie Civil" it appears that the number of building accidents, particularly those taking place during the construction of private dwellings, in St. Petersburg, Russia, has led the Russian Imperial Technical Society to initiate an investigation into the causes of the accidents. This investigation has shown that the owners of these dwellngs and more particularly the contractors, are generally lacking in any technical instruction, and, in addition, that there does not exist any competent municipal control able to make up for these defects in experience and knowledge. It also appears that there are no rules limiting the load which can safely be supported by different materials or different types of construction and that the contractors always are trying to make the low price material work as much as possible. Finally, they decided that in addition to the ignorance of the builders, there was a decided lack of understanding between the builders and their workmen.

To remedy these defects the investigators recommended that the city organize a building department with authority to supervise private construction and to fix maximum loads which should be allowed. To limit the use of poor material the committee recommended that a severe penalty should be imposed for the purchase of poor material, particularly when that material resulted in failure. To increase the knowledge of construction among both workmen and superiors the investigators concluded that it would be necessary

for the higher technical societies to create some technical societies of a lower order which might give instruction to [illegible]. Finally, the commission recommended that there should [illegible] an employers' liability law which would insure workmen against accident caused by the negligence of their superiors.

The Tai Tam Tuk Reservoir, now under construction for the water supply of Hongkong, China, will have a storage capacity of [illegible] U. S. gal. According to a brief note in the "[illegible] and Eastern Engineer" for July, 1914, the reservoir "is designed to catch the overflow from the Tai Tam proper and the Tai Tam intermediate reservoirs." Thus far the construction has proceeded to the extent of diverting streams and making it possible to store 60,000,000 U. S. gal. for use by pumping. The construction work "is being carried out under the supervision of the Public Works Department," and will require five years more for completion.

The Annual Improvement Work on Missouri Roads by volunteer laborers took place Aug. 19, 20 and 21. It is stated in newspaper reports that the number of volunteers was less by [illegible] than the number which turned out last year, when the scheme was inaugurated, but this is made a matter of congratulation by stating that many residents of cities turned out last year who proved to be more ornamental than useful, while this year the volunteers were farmers and country residents capable of doing a day's work. Governor Major spent the whole three days with a gang of 25 convicts. The Governor is optimistic enough to believe the state is a gainer by $1,[illegible] as a result of the three days of popular road work.

Trade of the United States With Other American Countries in the year ending June 30, 1914, aggregated $1,303,-[illegible], or 3[illegible] of the commerce handled by domestic ports. Of this, 956 million was with North America and 347 million with South America, according to recent statistics of the Department of Commerce, Washington, D. C. Imports from North American countries into the United States, valued at $[illegible], were chiefly from Canada, Cuba, Mexico, Central America and the British West Indies. Exports to these countries, amounting to $[illegible]29,000,000, were chiefly to Canada, next [illegible] Cuba, Central America and Mexico. Although the trade of the United States is very extensive in North America, this is not the case in South America. In Argentina, Brazil and Chile, for instance, only about 1[illegible] of the imports were from this country.

The Last Spike [illegible] a new railroad was driven at Nova, Ohio, Aug. 17. This event, now rare in the East, marked the completion of the Lorain, Ashland & Southern R.R., 78 miles long. It begins with a belt line at Lorain, on Lake Erie, and runs south to [illegible], on the Pittsburgh, Fort Wayne & Chicago R.R. (Pennsylvania System). It crosses two branches of the Lake Shore & Michigan Southern, the Wheeling & Lake Erie, the Cleveland, Cincinnati, Chicago & St. Louis, the Northern Ohio, the Baltimore & Ohio and the Erie roads. Most of the line has been built within a year and a half, though the [illegible] miles between the Erie and Pennsylvania lines [illegible] and Ashland) has been built 1[illegible] years. The road is [illegible] for about $[illegible],000, or $[illegible]6,000 per mile. [illegible] schedule operation will begin Sept. 1. Freight will be hauled by steam trains and passengers by storage-battery cars.

Another Concreting Record at Arrowrock Dam.—The June "[illegible] Record" gave what was believed to be a world's record for concrete placing with [illegible] mixers while at the Arrowrock Dam, [illegible] Project in April, 1914. The record was broken during May, according to July-August issue of the same journal. The following figures for the two months show that the April record was substantially exceeded in every particular during May:

	April	May
Total yardage for the month	[illegible]	[illegible]
[illegible]	6	6
[illegible]	3	3
[illegible]	18	18
[illegible]	3	3
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
Average [illegible] per day	[illegible]	[illegible]
Average [illegible] per hour [illegible]	[illegible]	[illegible]

A Remarkable Highway Bridge.—For [illegible] months a brick pavement with a concrete foundation on a rural road in [illegible] County, Ohio, has bridged a gap [illegible] ft. long and [illegible] ft. wide over a washed-out roadbed. The pavement was illustrated in "Engineering News" of [illegible] p. [illegible]. According to the August issue of "Dependable Highways," the [illegible] of National Paving Brick Manufacturers Association, this same pavement is still in use with no other safeguards than a few timber props and a guard rail to keep vehicles from venturing over the edge of the projecting shelf. The pavement is near Tinker's Creek, on the Durham road, where the washout occurred in March, 1913. It is said that after the washout, the road authorities attempted to break up the pavement with sledge hammers, but it resisted so tenaciously that traffic was allowed on it, and the road has been in use ever since. The chief cause of delay in backfilling the road foundation has been a project to divert the road to a new location.

Iron Ore Output in 1913 Largest.—The crude iron ore mined in the United States in 1913 amounted to about 62 million long tons, compared with 55 million in 1912, an increase of about 12[illegible]. The iron ore shipped from the mines in 1913 was about 60 million tons, valued at $131,000,000, compared with about 57 million tons, valued at $107,000,000 in 1912. The average price of ore per ton for the whole country in 1913 was $2.19, compared with $1.88 in 1912. These statistics include the ore used for fluxing other metallic ores at smelters in the Middle and Western States, but do not include the iron ore sold for the manufacture of paint. The latter ore in 1913 amounted to about 17,000 tons, valued at $[illegible],000.

Iron ore was mined in 28 states in 1913, the five largest producers were, Minnesota, Michigan, Alabama, New York and Wisconsin. The output of the Minnesota iron ranges amounted to five-eighths of the total. The Lake Superior district, comprising all the mines in Minnesota and Michigan and those in northern Wisconsin, mined 84.5% of the total.

A Report on the Reservoir Break at Turlock, Calif., described in "Engineering News," July 9, 1914, has been made by a committee of the affiliated commercial organizations of this irrigation district, confirming the probable causes set forth before. The report states (1) that the water forced its way through the south wing of the outlet gate on account of poor workmanship, (2) that the break was due to faulty filling behind the concrete bank lining, (3) that the fills along the north side of the Davis reservoir are faulty and porous, (4) that abnormal and alarming flows preceded the break but that the operating officials did not heed the warning. It is also reported (5) that the gate proper is undamaged, and (6) that there is good material available for an impervious earth fill. The committee recommends (1) strengthening all present fills "under the advice and immediate supervision of a first-class experienced engineer," and (2) appointing a general manager and superintendent for the district of "acknowledged ability and experience" to have control and supervision of the entire irrigation system, of the employing and discharging of employees, of the purchasing of supplies and auditing of bills. Several of the district directors have resigned.

An Ocean Car Ferry Steamer for through freight service between the United States and Cuba is being built for the Florida East Coast Ry. by the William Cramp & Sons Ship & Engine Building Co., at Philadelphia. It will run between Key West and Havana. It resembles the car-ferry steamers operating on Lake Michigan, having the bow and sides carried up to a deck over the track deck, so as to give a high freeboard in rough weather, while the stern is open for the passage of cars. The stern end of the track deck is shaped to fit the recessed end of the [illegible] pier, so as to adjust the boat and shore tracks in proper line. The boat was designed originally to be [illegible] ft. long, carrying [illegible] cars, but as built it is 3[illegible]0 ft. long and has capacity for [illegible] cars. It is [illegible] ft. wide and [illegible] ft. deep, and has a speed of [illegible] knots with 2[illegible] tons cargo load. There are four tracks, and when the cars are in place their bodies are supported by blocks, so that they cannot swing on the truck springs when the vessel is rolling. The double bottom has tanks for feed water and for water ballast when the vessel is light. There are also two tanks for carrying molasses, with pump equipment for handling this cargo.

The machinery consists of two triple-expansion engines, developing [illegible] hp. at [illegible] r.p.m., and steam is supplied by [illegible] boilers. Special arrangements are made for fitting guns to adapt the boat to naval or transport service. The officers and crew's quarters are in superstructure on the upper deck. The boat is nearly ready for launching and will be named the "Henry M. Flagler," after the late president of the railway, who originated the idea of the Key West extension (with its [illegible] viaducts) and the Cuba car ferry.

Proposed Municipal Water-Works for Birmingham, Ala., were reported upon by Julian Kendrick, City Engineer, on Aug. 1[illegible]. This report is printed in full in the Birmingham "Age-Herald" of Aug. 1[illegible], from which we have taken the following. Mr. Kendrick reports that a municipal plant can be built on the [illegible] River, where there is enough water to supply a city several times the size of Birmingham. The

site of the proposed pumping plant is at Glover Ferry between the proposed location of Locks 7 and 8, near the point where the Atlanta, Birmingham & Atlantic R.R. crosses the river. From the pumping plant a 48-in. force main is designed to be laid by way of Sterretts, passing through Coosa and Oak Mountains by means of tunnels, to a reservoir and filter site, near East Irondale, thence to the city's distribution system. The pumping plant will consist of one 12,000,000-gal. and two 8,000,00-gal. pumping engines—a total pumping capacity of 28,000,000 gal. per day. The pumps will operate against a head of 460 ft. The force main will be 117,600 ft., or 22.3 miles long.

Two storage reservoirs are planned at Slades Mountain with a total capacity of 300,000,000 gal. at an elevation of 800, or 35 ft. above the surface of the distributing reservoirs of the Birmingham Water Works Co. The proposed filter plant is designed to take 26,000,000 gal. per day. From the filter plant to the city's distribution mains, 32,000 ft. of 48-in. main will be required, and it is planned to spend about $1,500,000 on the distribution system. The estimated cost of the whole is approximately $4,500,000.

Under the present contract with the Birmingham Water Works Co., the city is required to pay 15c. per 1000 gal. for water, $55 per year for each fire hydrant, and the rate to private consumers ranges from 8c. to 30c. per 1000 gal. Mr. Kendrick reports that the city can sell water from the proposed plant for 10c. per 1000 gal. at a net profit of $52,560 per annum.

Temperatures of Ingots and Rails in Rail Rolling were measured by the Bureau of Standards at four rolling mills recently. The purpose was to determine prevailing practice regarding rail-rolling temperatures, find out what the shrinkage clause in rail specifications amounts to and determine if possible what parallel there is between physical properties of rails and rolling temperatures.

There is practical uniformity among the several mills for the rolling temperatures of ingots for steel rails, the range being from 1975° F. to 2085° F. There is no very considerable difference among the finishing temperatures of the rails at the hot saws, the range being about 1615° F. to 1815° F, the average, 1715° F., is 520° above the critical range of rail steel. Chemical analyses and micrographic examinations, together with tests of the chemical properties from samples of the rail whose tempertures have been observed, showed no particular relation between these various factors and the rolling temperatures.

The observations covered both openhearth and bessemer steel, the former having 0.65 to 0.70% carbon, and the latter 0.40 to 0.50% carbon. The melting points of the steel range from about 2680° F. to nearly the melting point of iron at 2786°. The critical point of the steel on heating was about 1350°, and on cooling —about 1230°.

The doefficient of expansion for openhearth and bessemer steel was found to be different. Between 0 and 1800° F. the linear coefficient per degree Fahrenheit was 0.0000081 for bessemer, and 0.0000087 to 89 for openhearth. On this basis the shrinkage allowance of 6¾ in. in 33 ft. fixed by the American Society for Testing Materials in 1909 specifications allows temperatures of 1947° F. to 2055° F., which is very far above the critical range of the steel. Thus the specification, the Bureau points out, does not serve its avowed purpose of limiting the finishing temperature to a value slightly above the critical range.

PERSONALS

Mr. J. W. Barrie, Principal Assistant Engineer of the Florida East Coast Ry., has resigned, and the office has been abolished.

Dr. George F. Swain, Past-President of the American Society of Civil Engineers, of Harvard University, was married on Aug. 21 to Mrs. Mary Augusta Rand, daughter of Mrs. George W. Batchelder, of Ipswich, Mass.

Mr. Fred. W. Lepper, M. Am. Soc. C. E., recently Supervisor of Construction of the building of the Bureau of Engraving and Printing, Washington, D. C., has been transferred to Augusta, Ga., to supervise the construction of the new Post Office building.

Mr. H. A. Butz, for the past four years Chief Engineer of the Dominion Iron & Steel Co., Ltd., Sydney, Nova Scotia, has resigned. The company has discontinued all construction work for an indefinite period, due to present war conditions. Mr. Butz was formerly with the Garrett-Cromwell Engineering Co., Cleveland, Ohio.

Mr. Morgan. K. Barnum, recently General Mechanical Inspector of the Baltimore & Ohio R.R., has been promoted to be Superintendent of Motive Power, with headquarters at Baltimore. He is a graduate of Syracuse University, class of 1884, and began his railway experience as a special apprentice in the shops of the New York, Lake Erie & Western R.R. at Susquehanna, Penn.

Mr. Hale Holden, Vice-President of the Chicago, Burlington & Quincy R.R., has been elected President to succeed the late Darius Miller, whose death was noted in our issue of last week. Mr. Holden was born in Kansas City, Mo., in 1869, and is a graduate of Williams College and Harvard Law School. His railway service began in 1907, and from 1910 to 1912 he was General Attorney of the Chicago, Burlington & Quincy R.R.

Mr. Ant. Decarie, Chief Inspector of the sewer department, northern division, Montreal, Que., and three of his Assistant Inspectors have been dismissed for alleged incompetency and irregularity in connection with the construction of the Notre Dame de Grace sewer. The dismissal of Mr. E. Pelland, Engineer in charge of the sewer department, for alleged graft in connection with the construction of this sewer, was noted in our issue of July 23, 1914.

OBITUARY

T. C. Chase, former Building Inspector of Denver, Colo., and for the past seven years connected with the construction department of the Denver Union Water Co., died Aug. 21. He went to Denver in 1879 from Massachusetts.

Edgar Thaddeus Welles, Vice-President of the Wabash R.R., died Aug. 22, at his home in New York City. He was born in Hartford, Conn., Aug. 29, 1843, and was the son of Gideon Welles, Secretary of the Navy under President Lincoln.

William E. Harwig, Supervisor of Bridges and Buildings of the Lehigh & New England R.R., died Aug. 24, at his home in Phillipsburg, N. J. He entered the service of the Lehigh Valley R.R. in 1878, and for 10 years, 1902 to 1912, was Supervisor of Bridges and Buildings.

Bernhardt W. Pohler, for 24 years an engineer with the American Bridge Co., died July 27. He was born in Denmark, Mar. 10, 1858, and graduated from the Royal College of Denmark in 1884. He is survived by a widow, whose present home is 4440 Dover St., Chicago, Ill.

Charles F. Baker, until about six months ago Mechanical Engineer of the Bay State Street Ry., Boston, Mass., died recently in East Orange, N. J. He was born in Vermont 59 years ago. In 1893 he was Master Mechanic of the West End Street Ry., Boston, Mass., and was later with the Boston Elevated Ry. as Superintendent of Motive Power and Equipment. In 1904 he was President of the American Electric Railway Association.

Roderick J. McD. Parke, Assoc. M. Can. Soc. C. E., Consulting Engineer, of Toronto, Ont., died Aug. 25, at his home in that city. Mr. Parke was the designer of one of the first long-distance electric transmission lines in Canada, that from Ragged Rapids, on the Severn River, to Orillia. He also designed light and power plants for numerous towns in Ontario. As Consulting Engineer for the Canadian Government, he had charge of the design of the lighting equipment of the Welland Canal.

Berthold Charles Kaiserling, recently with the city engineering department of San Antonio, Tex., was accidentally killed July 5, by a passenger train of the Southern Pacific Ry., at Galveston, Tex. Mr. Kaiserling was a civil engineer of wide experience in Mexico and South America, and he had just left the employ of the city of San Antonio to accept a position in South America. He had been with the engineering corps of the Mexican Central Ry. and of the Guayaquil & Quinto R.R. in Ecuador. At one time he was in charge of harbor work at Vera Cruz, Mex. He had also seen service in Guatemala. Mr. Kaiserling is survived by a widow, whose home is 113 Oak St., San Antonio, Tex.

William de Hertburn Washington, M. Am. Soc. C. E., Consulting Engineer, New York City, died Aug. 30, at the New York Hospital, from cerebro-spinal meningitis, after an illness of three days. He was born in Baltimore, Md., June 29, 1868, and traced his descent to John A. Washington, a brother of George Washington, of Mount Vernon, Va. He was for a time in the consular service in Canada. About 20 years ago, he came to New York City and for several years was President of the Hydraulic Construction Co. Later he was in the real estate business. Of recent years, he has been

[illegible] as a [illegible] engineer [illegible] member of the [illegible] of engineers which [illegible] New York State highway work [illegible].

Prof. Adolf Martens died on July [illegible], 1914, at 64 years of age. For [illegible] years he had been Director of the Royal Prussian testing laboratory, first at Charlottenburg, and since [illegible] at Gross-Lichterfelde. Raising this institution to [illegible] among testing laboratories was Martens' great work. His name will be longer remembered, however, by his metallographic work (martensite, the chief constituent of hardened steel, is named after him), by his endurance tests [illegible] of them still running), by his designing [illegible] original and improved instruments and machines for testing (the mirror extensometer and the diaphragm pressure-gage are among the best known), and by his efforts [illegible] testing [illegible] scientifically reliable [illegible]. In the latter regard he stood virtually alone, yet [illegible] enough to leave a long enduring impress on the testing world. Among other writings, he published an authoritative work on materials, which has been translated into English. He was one of the active spirits of the International Association for Testing Materials; his visit to America at the 1912 congress of that body in New York is doubtless remembered by many American engineers.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN MINE SAFETY ASSOCIATION.
Sept. [illegible]. Annual meeting in New York City. Secy., H. D. [illegible], Bureau of Mines, Pittsburgh, Penn.

AMERICAN FOUNDRYMEN'S ASSOCIATION.
Sept. [illegible]. Annual meeting at Chicago, Ill. Secy., A. P. [illegible], Cleveland, Ohio.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.
Sept. [illegible]. Annual convention at Buffalo, N. Y. Secy., Will [illegible], Cleveland, Ohio.

NATIONAL ASSOCIATION OF PORT AUTHORITIES.
Sept. [illegible]. Annual convention in Baltimore, Md. Secy., [illegible], New York City.

[illegible] AND MAINTENANCE OF WAY ASSOCIATION OF AMERICA.
Sept. [illegible]. Annual meeting at Chicago, Ill. Secy., L. C. [illegible], Ill.

[illegible] CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION.
Sept. [illegible]. Annual convention in Nashville, Tenn. Secy., A. [illegible], Mass.

NEW ENGLAND WATER WORKS ASSOCIATION.
Sept. [illegible]. Annual convention in Boston, Mass. Secy., [illegible], R. I.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.
Sept. [illegible]. Convention in Atlantic City, N. J. Secy., [illegible] Bureau, Philadelphia, Penn.

ILLUMINATING ENGINEERING SOCIETY.
Sept. [illegible]. Annual convention in Cleveland, Ohio. Secy., [illegible], New York City.

RAILWAY SIGNAL ASSOCIATION.
Sept. [illegible]. Annual convention in [illegible], N. Y. Secy., [illegible], Penn.

[illegible] ASSOCIATION.
Sept. [illegible]. Annual convention at New York. Secy., [illegible], Philadelphia, Penn.

INTERNATIONAL IRRIGATION CONGRESS.
[illegible]

AMERICAN ELECTRIC RAILWAY ASSOCIATION.
Oct. 12-16. Annual convention at Atlantic City, N. J. Secy., E. B. Burritt, 29 West 39th St., New York City.

NATIONAL COUNCIL FOR INDUSTRIAL SAFETY.
Oct. 13-15. Annual safety congress at Chicago, Ill. Secy., W. H. Cameron, Continental Bank Building, Chicago.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.
Oct. [illegible]. Convention at Los Angeles, Calif. Secy., C. A. [illegible], Chicago, Ill.

Kansas League of Municipalities—The League [illegible] will meet at Lawrence, Oct. [illegible], to discuss the [illegible] of cities [illegible].

Central Railway Club—[illegible]

Upper Mississippi River Improvement Association—The [illegible]th annual convention will be held at Stillwater, Minn., Sept. 16-[illegible]. Invitations have been sent to the Governors of Iowa, Missouri, Minnesota and Wisconsin, to the Mayors of all municipalities in the Upper Mississippi Valley, and to kindred waterway associations. The Secretary is L. H. Boswell, Quincy, Iowa.

American Electric Railway Association—The annual convention of this Association and its affiliated bodies, the American Electric Railway Accountants', Engineering, Claims and Transportation and Traffic Associations, will be held in Atlantic City, Oct. 12-16, at Young's Million Dollar Pier. At the same time the American Electric Railway Manufacturers' Association will hold an exhibit of electric-railway appliances. The secretary is E. B. Burritt, 29 West 39th St., New York City.

The American Boiler Manufacturers' Association—The program for the 26th Annual Convention of the Association, to be held in New York City, Sept. 1-4, has been arranged as follows: Addresses of welcome will be delivered by Hon. Henry Bruere, City Chamberlain, and Charles R. Lamb, a director of the Merchants' Association of New York. The business session will be held that afternoon, and in the evening the reception at the Waldorf-Astoria. At other sessions the following committees will report: Uniform Specifications, Uniform Boiler Laws and Uniform System of Cost Keeping, and Topical Questions. The banquet will be held on the evening of Sept. 3.

National Council for Industrial Safety—The third annual "Safety Congress" will be held at the La Salle Hotel, Chicago, Oct. 13 to 15. There will be addresses, reports of committees, papers, moving-picture displays and also an exhibit of safety devices and methods. Different sessions will be devoted to government work, the economics of safety, industrial hygiene, safety in transportation and public service, and safety in manufacture.

According to the [illegible] report of the secretary, the Council established its headquarters in Chicago in October, 1913. It has now 731 member companies or firms with 2155 representatives in the council, having about [illegible] employees. One of the principal activities of the organization is in the distribution of bulletins [illegible] and other information relative to the safety movement. President, R. W. Campbell, Illinois Steel Co., Chicago; Secretary, W. H. Cameron, Continental and Commercial Bank Building, Chicago.

Central States Water-Works Association—The 18th annual convention was held at the Windsor Hotel, Wheeling, W. Va., Aug. 25 to 27, inclusive. The address of President J. C. Martin, of Wellington, Ohio, covered briefly the history of the Association and the problems which were [illegible] before it and its members in the increasing density of population and the contamination of streams. F. W. Collins, Superintendent of the Water Department of Manistee, Mich., described the working of the commission plan of city government in Manistee, which has a population of about [illegible], where it has evidently been an unqualified success. C. H. [illegible], City Engineer of Wheeling, described various methods used to filter and treat Ohio River water by the cities which are obliged to use it for potable water supplies. The paper [illegible] chiefly in elementary principles of water purification. He stated that Wheeling had been [illegible] negligent in regard to water purification and that the typhoid fever death rate for the [illegible] years ending in 1913 was [illegible] per 100,000 per annum. In July, the city voted for a filter plant, and the city engineering staff are now working on plans and surveys. The system of water purification which received a preferential vote of the people last July is the [illegible] system, invented by L. [illegible], of Charleston, W. Va., and was described by him in a paper on the filtration and purification of the Ohio River water. Mr. [illegible] described the method by reference to the plant now in operation at Parkersburg, W. Va., as the best [illegible], which has been in operation for three years. This plant consists of [illegible] strainer [illegible] in the bed of the river. These strainers are joined to collector pipes leading to pump wells on shore. The water is filtered by the natural sand and gravel bed of the river itself. For washing the filter bed if it becomes [illegible], water may be forced back through collector pipes and strainers. The method adopted by the city of Wheeling in selecting the type of water purification plant to be built is a [illegible] one, [illegible] by the W. L. [illegible], engineer of the West Virginia State Board of Health. On the afternoon of Aug. 27 an excursion was made to the Wheeling city waterworks. The place selected for the next convention is [illegible], Ohio. The following officers were elected: President, F. W. Collins, Manistee, Mich.; Vice-President, [illegible]; Secretary, [illegible]; Treasurer, [illegible].

Engineering News

VOLUME 72 SEPTEMBER 10, 1914 NUMBER 11

The Farmville High Bridge across the Appomattox Valley

By F. P. Turner*

One of the longest and highest bridges on the Norfolk & Western Ry., known as Farmville High Bridge, has just been rebuilt as a double-track structure in connection with the extension of double-track between Roanoke and Norfolk, Va.

Historical

The line here crosses the Appomattox River and Valley, 145 miles west of Norfolk, Va., and the first bridge was built in the year 1853 as a part of the South Side R.R., connecting Petersburg and Lynchburg, Va. Information obtained from the files of the Engineering Department shows that the road was located after a careful study of the intervening country by C. O. Sanford, Chief Engineer, and built under his direction to secure not only a low first cost but an economical operation.

Briefly described, this line, after rising out of the James River Valley at Lynchburg, follows the top of the ridge which divides the waters of the Appomattox and Roanoke Rivers, in an easterly direction to Petersburg. On this location, grades of 16 ft. per mile could easily be obtained. The one exception to this is near Farmville, where it left the ridge route and crosses high above the Appomattox River Valley, returning again to the summit of the ridge several miles to the eastward.

The Chief Engineer's report shows that several conditions influenced the doption of this route. Chief among them may be mentioned:

(1) The loss of a large amount of tonnage from Farmville if the ridge route had been followed.

(2) The residents of Farmville made an urgent appeal for the line to pass through their town, and raised a subscription to purchase stock amounting to $100,000. This, in the early stages of railroad development, was a matter of considerable moment.

(3) The adoption of the Farmville route would advance the completion of the road one year.

(4) This route was 5 miles shorter than the ridge route.

The greatest obstacle to the construction of this line was the expensive bridge over the Appomattox River and Valley.

First Bridge—The bridge as originally built was 3400 ft. long, varying in height from 60 ft. at the abutments to 100 ft. at the river; clear spans 105 ft. in length. Previous to this time longer bridges, not so high, and higher bridges, not so long, had been built, but taking the length and height together this was thought to be the largest bridge in the world.

From a standpoint of economy, wood instead of iron was chosen for the superstructure, and was also given consid-

*Bridge Engineer, Norfolk & Western Ry. Co., Roanoke, Va.

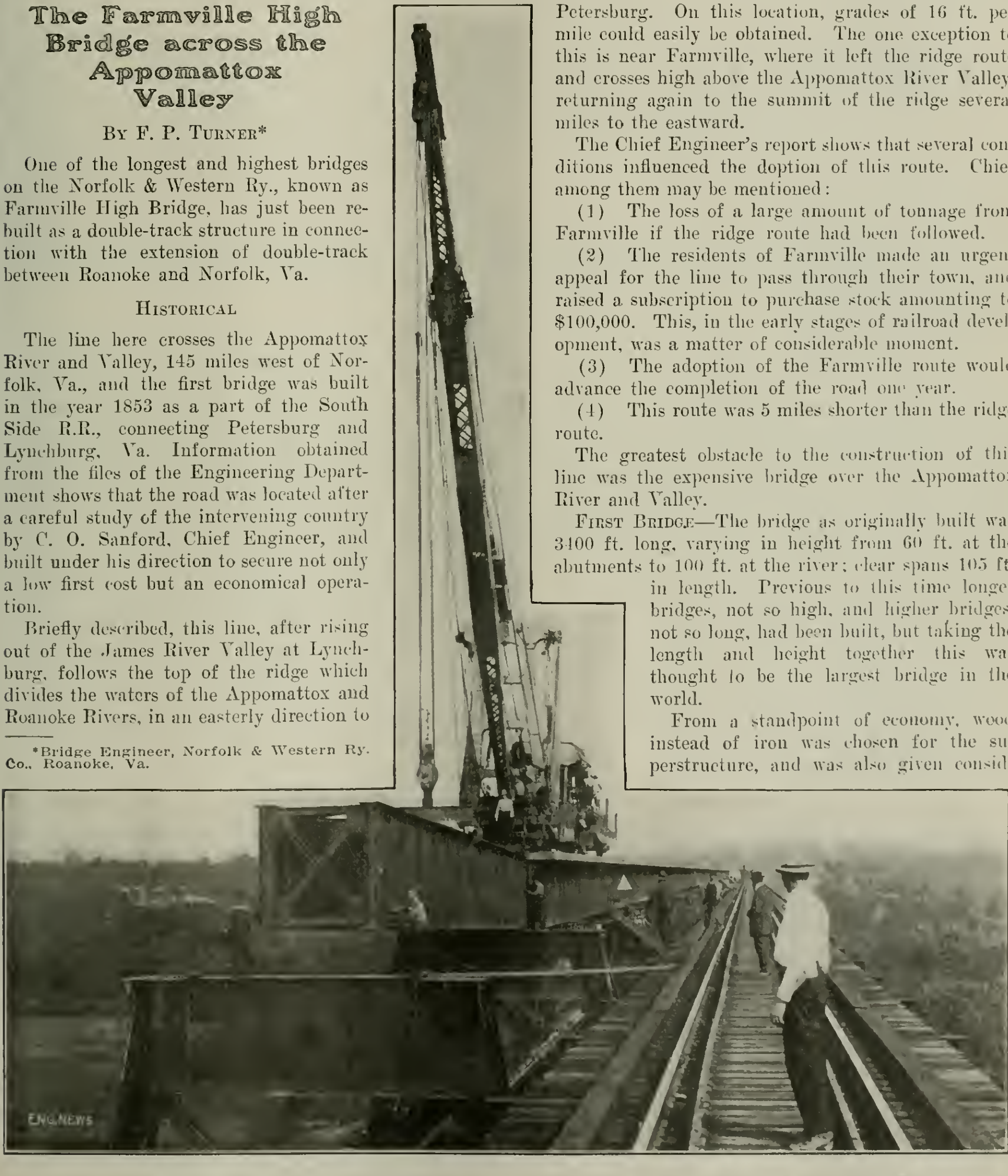

Fig. 1. Placing a Completely Riveted 72-Ft. Plate-Girder Span on the Farmville High Bridge, N. & W. Ry.

erations for the piers. After an examination of a number of higher structures built of brick in several cities of the United States, and having greater unit pressures at the bottom, the successful results obtained warranted the selection of this type of construction for the piers. This decision too was influenced somewhat by the presence in the immediate vicinity of the bridge of a brick clay of superior quality, which would make the estimated cost of the piers about one-third that of stone construction.

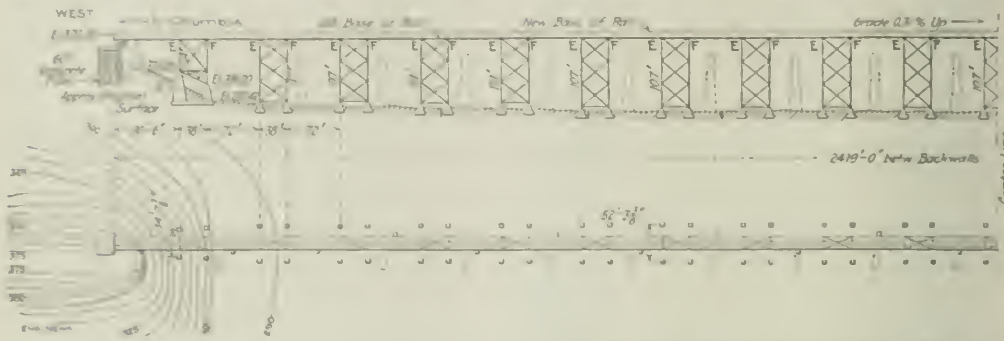

FIG. 2. PLAN AND ELEVATION OF THE NEW FARMVILLE

The abutments were built of rubble masonry, and the bases of the piers to a point 3 ft. above the high-water mark were built of stone masonry with cut beds and joints. The foundations extended about 8 ft. below the ground, resting on clay and gravel. The piers were of brick masonry 8x22 ft. at the top; 14x27 ft. at the bottom and were 82 ft. high above ground. The foundations of those adjacent to the river probably extend to solid rock.

Wood superstructure was anchored to the foundation by iron rods passing entirely through the piers in shafts left for the purpose. The estimated cost of the wooden trusses of the superstructure was $18 per lin.ft., and the total cost of the bridge was $167,500. It was built to carry engines weighing 32 tons, although the ones in use at that time weighed only 16 tons.

SECOND BRIDGE—The superstructure was rebuilt in 1870 as a metal structure, the length being reduced to 21 spans, 110 ft. $3\frac{1}{4}$ in. c. to c. of end bearings. It consisted of deck Fink trusses, built by the firm of Smith, Latrobe & Co., of Baltimore, of Phoenix Iron Co.'s material. The bridge was designed for a live-load of about 1850 lb. per lin.ft. of track; the spans weighed about 70,000 lb. each and were in service until 1886.

THIRD BRIDGE—In February, 1886, proposals were invited to strengthen the Fink trusses or construct a new bridge capable of sustaining loads that agree with Cooper's E-24 class, followed by a uniform load of 3000 lb. per ft., the present trusses having only 50% of the strength to safely carry this weight.

Deck Pratt trusses, built of iron, with steel eye-bars, were adopted and were fabricated and erected during the summer of 1886, the contractors being the Edge Moor Iron Co. & Frederick H. Smith. These spans were 12 ft. $4\frac{1}{2}$ in. c. to c. of trusses, 15 ft. 9 in. c. to c. of chords, and consisted of seven panels 15 ft. 9 in. each, making a total length of 110 ft. 3 in. c. to c. of bearings. The ties rested directly on the top chord. The weight of metal per span was about 60,000 lb., and the bridge cost $75,000 erected in place. The record of erecting shows that five of these spans were erected under traffic in 12 days.

FOURTH BRIDGE—The 1886 spans, resting on the brick piers, carried the increased traffic until 1901, when they were reinforced by the addition of a third truss placed midway between the existing ones and braced to them. A metal floor system was added at the same time, the floor-beams resting on top of the three trusses, the middle truss being designed to carry 48% of the live load from a concentration of four 15,000-lb. axles, 5 ft. c. to c., with a uniform load of 1000 lb. per lin.ft. of track at a 10-ft. interval in either direction. These spans were built by the American Bridge Co.'s Edge Moor plant, the material being soft steel except the eye-bars, which were of medium steel.

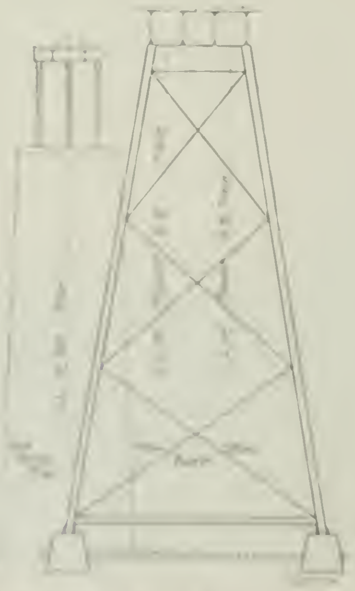

FIG. 3. COMPARATIVE CROSS-SECTIONS OF OLD AND NEW BRIDGES

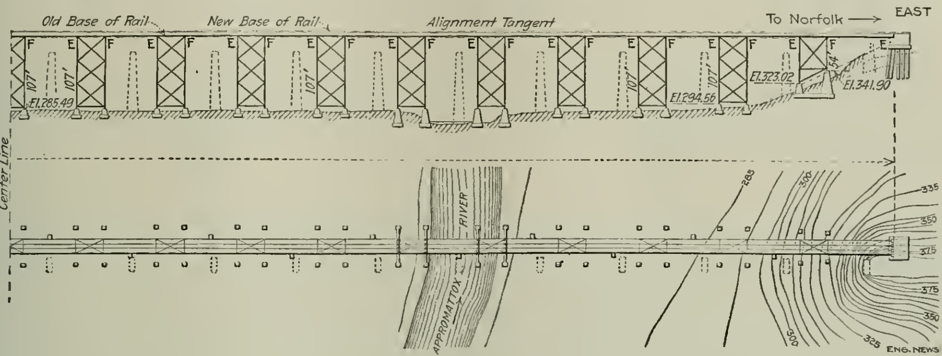
The installation of the third truss and floor system was made under traffic, the grade being raised about 2 ft. to accommodate the new floor system. This latter structure carries safely the present-day traffic, with axle loads as high as 57,000 lb.

Present Bridge

As stated above, the brick piers supporting these spans have shafts in them tapering in size from top to bottom. This condition, together with the vibration from heavy traffic, caused several of the piers to crack near the top. A number of years ago the piers were strengthened by placing bands of steel bars, at about 8-ft. intervals from the top, around the piers, connecting to angles running down the corners. These bands are clearly shown in the views.

Increased traffic which required the extension of the double-track lines into this territory, together with the appearance of additional cracks in the piers from time to time, caused a study to be made of plans for renewing this bridge for a double-track structure. Surveys were made and plans prepared in the latter part of 1912 for the construction of a double-track steel viaduct, with the center line of the near track parallel to and 20 ft. to the north of the center line of the existing bridge. The cross-section, Fig. 3, shows the relation between the old and the new structure, it being such as to permit the construction of the foundations and the erection of the steelwork without endangering the old substructure, superstructure, or interfering with traffic. Curves, near each end of the bridge, permitted the alignment to be easily adjusted on account of the offset.



High Bridge and (Dotted) the Old Substructure

Revision in the grades in this territory made it necessary to raise elevation of the base of rail on the new structure about 7 ft. higher than the old, in order to keep within the ruling grade of 0.3 against the eastbound coal traffic.

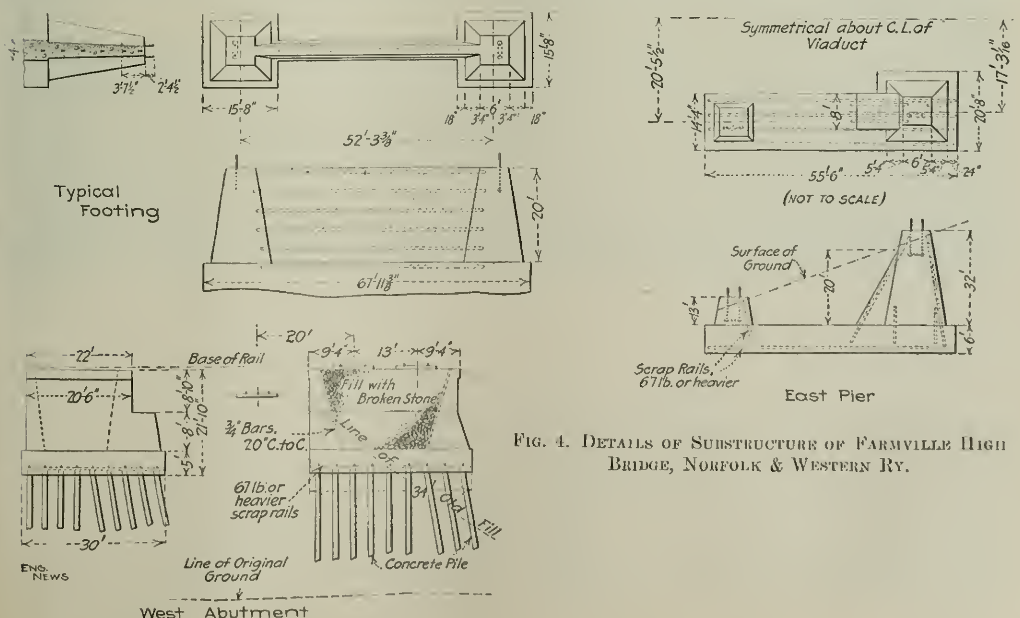


Fig. 4. Details of Substructure of Farmville High Bridge, Norfolk & Western Ry.

The approach embankments at the two ends were made from borrow pits, with short haul, the material being excavated with steam shovel and dumped from light trestles alongside the fill. The materials available for making the fills contained minerals of soapstone and talc formation, which gave it a disposition to slip, slides having previously occurred several times in the old embankment from this same cause. This matter was given careful consideration in the preparation of plans for the new structure, with the result that slopes of two horizontal to one vertical were adopted for the fills. As a further precaution the fill was made in three lifts, the material being placed in the outer edges of all slopes with scrapers after dumping from cars and kept in horizontal layers. A ditch was cut about 25 ft. from the foot of the slopes to care for drainage at the base. The approach fill at the west end is about 1800 ft. long; at the east end about 400 ft. long; the two contain 171,000 cu.yd.

The Cummings type reinforced-concrete piles was selected and manufactured at the site and driven by the Cummings Structural Concrete Co., of Pittsburgh, Penn. They are octagonal in section; 17 in. between parallel sides for 20 ft., tapering to 9-in. section, 15 in. from the point; their design is shown in Fig. 5. Heavy spiral reinforcement, ⅜-in. round, ¾- to 1½-in. pitch, is used near the top to resist the blow of the hammer. The piles were molded during the summer and fall of 1913 on platforms underneath the bridge. The reinforcement was placed in the forms and blocked away from the boards so that concrete would properly cover the metal. The top board was left off for pouring the concrete.

The mixture was 1:2:4, with one additional bag of cement per cubic yard of concrete, or about 1.75 bbl. of cement per cubic yard. Broken limestone, size 1 in., was used. Forms were removed after two days and piles were then allowed to cure from 30 to 60 days before driving.

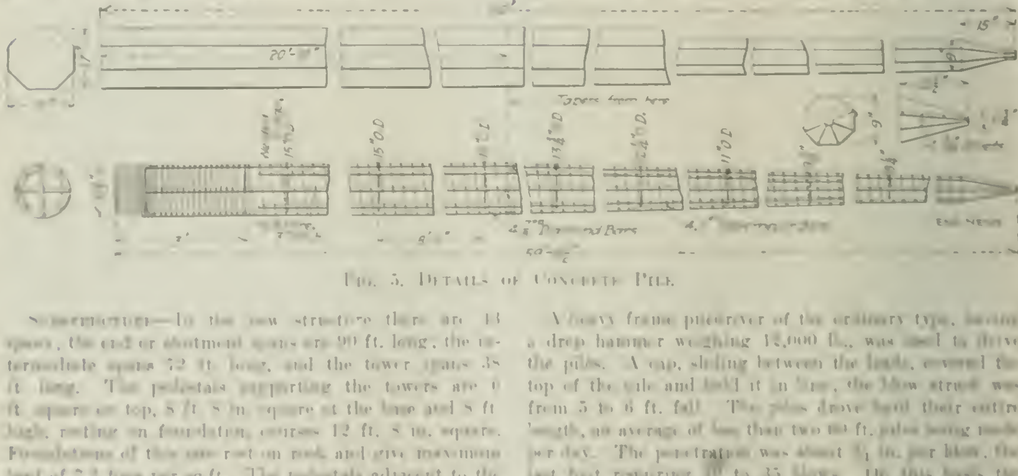

Fig. 5. Details of Concrete Pile

Substructure.—In the new structure there are 13 spans, the end or abutment spans are 90 ft. long, the intermediate spans 72 ft. long, and the tower spans 38 ft. long. The pedestals supporting the towers are 6 ft. square on top, 8 ft. 8 in. square at the base and 8 ft. high, resting on foundation courses 12 ft. 8 in. square. Foundations of this size rest on rock and give maximum load of 7.3 tons per sq.ft. The pedestals adjacent to the river were tied together with concrete struts, reinforced with steel rods, to prevent the accumulation of drift between them.

The pedestals supporting the first tower on either end vary from 20 to 40 ft. high, and the two on either side of the viaduct have a continuous foundation parallel with the track, the upper or higher pedestal is also buttressed with concrete, reinforced with steel rails, to resist the earth pressure from the fill which spills around it. The [illegible] in Fig. 2 shows the arrangement clearly. The foundations adjacent to the river, and practically all others in the low ground, extend to rock, a distance of about 25 ft. below ground.

The abutments, U-shaped, rest on the old fill about 30 ft. below the base of rail. Broken stone fill [illegible] used between the wing walls and earth spills around the [illegible]. Steel-rail reinforcement was liberally used in the [illegible] and wing walls of the abutments to counteract the tendency to crack from any slight settlement that may occur from shrinkage of the fill.

Precast reinforced-concrete piles, cast at the bridge site, were adopted to support the two abutments. Lengths of 30 to 60 ft. were required to make these pedestals to the original ground line. The outside piles were driven on a batter.

A heavy frame piledriver of the ordinary type, having a drop hammer weighing 12,000 lb., was used to drive the piles. A cap, sliding between the leads, covered the top of the pile and held it in line, the blow struck was from 5 to 6 ft. fall. The piles drove hard their entire length, an average of less than two 60-ft. piles being made per day. The penetration was about ¼ in. per blow, the last foot requiring 30 to 35 blows. On this basis the piles have a resistance of 40 tons as calculated by the Engineering News formula, the actual load being 25 tons, including the weight of the pile, which is 6 tons; pressure per square foot on foundation bed, 1.6 tons. Good results were obtained in driving, only a small number being damaged at the top. These were cut off 3 to 4 ft. from the end.

The concrete for the pedestals and abutments was made according to Norfolk & Western standard specifications of 1:2:4 mix, with broken limestone to pass through a 2-in. ring, all dirt and dust being screened out. Good sand was secured by pumping from the river.

Plant.—The contractor's plant was located on the low ground near the west end of the bridge. All material was delivered to this plant by a low-grade track leaving the main line about one mile west. The contractor's equipment consisted of a 10-ton locomotive crane, with orange-peel bucket, used for excavating foundations. This crane also handled the concrete buckets when depositing into forms, the pile hammer to drive sheet piling and many other kinds of work in connection with this contract. Cars were used for handling the concrete from the mixer to the various pedestals, a construction track having been laid between the pedestals from one end of the work to the other. Concrete mixers, derricks, hoisting en-

gines were supplied to meet the requirements of handling the materials rapidly when needed. Work on the foundations and fills began in May, 1913, and was completed in April, 1914, a total of 10,908 cu.yd. of concrete being placed.

SUPERSTRUCTURE—The viaduct was designed according to the Norfolk & Western specifications of 1911 for a live-load of five 55,000-lb. axles, 5 ft. c. to c., and a uniform load of 5500 lb. per foot on either end at 10-ft. intervals. Double-web cross-girders, 7 ft. deep, were used at the top between the columns to furnish support for the two center girders, the outside girders resting di-

four angles 6x4x$\frac{9}{16}$ in., two webs 24x$\frac{9}{16}$ in., double laced on the inside, with 3x$\frac{5}{8}$-in. lace bars. Columns are built in two sections, with a batter of 2 in. in 12 in.; the base plates are 4 ft. 2 in.x5 ft.x1$\frac{1}{2}$ in. thick, and are anchored to the pedestals by two 1$\frac{3}{4}$-in. bolts 6 ft. long, built 3 ft. 6 in. in the concrete with an anchor plate 6 in. wide, placed on the lower ends of the bolts.

The longitudinal and transverse bracing is a double system, capable of taking both tension and compression, and is made up of four angles 5x3$\frac{1}{2}$x$\frac{3}{8}$ in. and 6x4x$\frac{3}{8}$ in., with single lacing 2$\frac{1}{2}$x$\frac{3}{8}$ in. for transverse bracing, and double lacing the same dimensions for the longitudi-

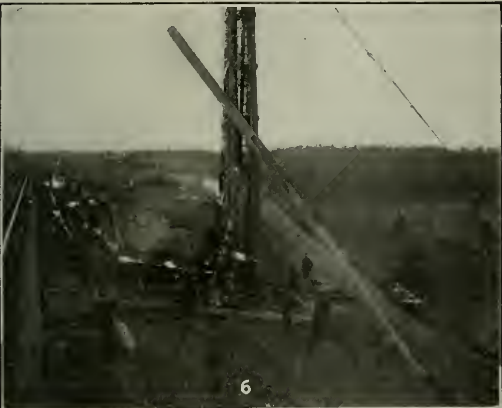

FIG. 6. SLINGING A 60-FT. PILE ONTO THE DRIVER

FIGS. 6-9. DRIVING CONCRETE PILES ON FARMVILLE BRIDGE ACROSS APPOMATTOX VALLEY

rectly on the column cap, diaphragms and stiffeners being used under the bearings of the center girders. The deck girders, spaced 6 ft. 6 in. c. to c., are 7 ft. 6$\frac{1}{2}$ in. deep, back to back of flange angles. A standard floor of 8x10-in. bridge ties 12 ft. long, dapped to 9$\frac{1}{2}$ in. and spaced 13 in. c. to c., is used, with 6x8-in. guard timbers outside the rails, notched down 1 in. over the ties, and 85-lb. steel guard rails inside.

The columns are made up of one cover-plate 28x$\frac{9}{16}$ in.;

nal bracing. The bottom struts are made of two 15-in., 33-lb. channels, double laced. Tower bracing in a horizontal plane is made of four angles 5x3$\frac{1}{2}$x$\frac{3}{8}$ in., double laced.

ERECTION—The girders, with the exception of the two 90-ft. spans, were delivered completely riveted in pairs, and unloaded on the east end at grade alongside construction tracks. All the column sections, bracing and cross-girders were delivered and unloaded alongside the con-

FIG. 10. ERECTING THE NEW FARMVILLE BRIDGE OF THE NORFOLK & WESTERN RY., ACROSS THE APPOMATTOX VALLEY

struction track running between the pedestals on the low ground.

The bottom section of each bent was erected and all bracing placed, using a 75-ton locomotive crane working on the low track. The top section of each bent was assembled and left standing alongside the bottom section, where it could be lifted to its final position with a [illegible]-ton derrick car, using an 80-ft. boom, and working from the completed viaduct above. The top section of the rear bent of each tower was placed, the derrick car standing at the end of the track over the preceding tower. The 72-ft. girder span, weighing 36½ tons, was next run out on a truck to the end of the track, and set off on the [illegible] in a temporary position; the derrick car then backed off the bridge so the truck could be gotten out of the way, whereupon [illegible] returned and placed the span in position. The tower was then completed and the tower span placed.

Erection of the steel began, Apr. 1, 1914; the first span was placed, Apr. 7; last span placed, June 9; erecting completed, May 11 [illegible], June 18, and traffic diverted over the new structure, June 20.

As the double track has not reached the immediate vicinity of this bridge, girders for only one track are placed at this time. The total weight of metal is [illegible] lb. Metal in the 72-ft. towers, per foot of length, weighed [illegible] lb.; per foot of track it weighed [illegible] lb. Girders, per foot of track, weighed [illegible] lb.; total weight of bridge as constructed, [illegible] lb. per lin.ft. of track.

ENGINEERS AND CONTRACTORS

The work was started under the direction of Chas. S. Churchill, Chief Engineer; Chas. C. Wentworth, Principal Asst. Engineer, and J. E. Crawford, who, as Bridge Engineer, prepared masonry plans and supervised the design of the steelwork. It was completed under the direction of J. E. Crawford, as Chief Engineer. A. Branch, Assistant Engineer, was in charge of all double-track construction and W. W. Vail was Resident Engineer on the work.

The Virginia Bridge & Iron Co., of Roanoke, Va., designed the steelwork, furnished and erected the structure.

Messrs. W. W. Boxley & Co., contractors, of Roanoke, Va., built the masonry and approaches.

A Fireless Locomotive for use at powder magazines and [illegible] has been supplied to the British army [illegible]. The engine was built by Andrew Barclay, Sons & Co., of Kilmarnock, Scotland.

Asphaltic Concrete Surfacing for Suburban Roads, Chicago, Ill.*

Suburban roads about Chicago have cost approximately 20c. per sq.yd. per year to maintain, and at no time has there been a road with a smooth wearing surface. In three years, the cost of upkeep on each macadam road, it is estimated, will approximately equal the first cost of an asphaltic concrete surface, 2 in. thick, which can be placed by municipal forces for between 50 and 60c. per sq.yd.

The low cost of this work is largely attributed to the planning of the work, provision of modern municipally owned equipment and to the efficiency of the organization. It is estimated that the macadam road covered by 2 in. of asphaltic concrete will not require any repairs for five years and that with reasonable repairs, this pavement will last 20 years.

The repair and maintenance of roads and pavements in Chicago is under the general direction of the Superintendent of Streets and under the immediate supervision of the general foreman in charge of the gangs, which are distributed in different sections of the city. The planning of the work is done by a number of civil engineers who report directly to the superintendent in charge of street repairs. In all cases, the street-repair foreman in charge of gangs works in conjunction with the superintendent of the ward in which the work is being done.

All asphaltic material required for the repair of pavements and roads is manufactured by the Bureau of Streets at the municipal asphalt plant and by a portable asphalt plant. These materials are transported by municipally owned vehicles, and the work is done by the organization which is recruited from civil-service lists.

*Mainly from an article prepared for the Journal of the Chicago Automobile Club, by J. L. Jacobs, Efficiency Engineer in Charge, City Service Commission, Chicago, Ill.

The portable asphalt plant can be moved about on the outskirts of the city where it is proposed to resurface macadam streets with bituminous top. This reduces the cost of long team haul, which is usually a large factor in the cost of repairing pavements. Under this arrangement material is received on the track beside the portable plant where it is manufactured and transported to the job by 5-ton motor trucks, recently purchased by the Bureau for this work.

Appropriations have been provided and specifications prepared for another portable plant which is to be used to utilize old asphalt top, which heretofore had to be transported and discarded at a large cost. The old asphalt will be brought to this portable plant, crushed and reheated together with new material, and taken back to the job to be used as binder. In this way the expense of long haul and waste of old material will be materially reduced and the capacity for new work will be proportionately increased.

In order to keep all the equipment in good condition, shops and storage sheds have been provided, and all the equipment is overhauled during the winter months, so there is little or no breakage or delay on account of run-down equipment during the working season.

Careful cost records are kept of the repairs to various types of pavement, and yearly averages are published in the report of the Public Works Department.

Engineering Vernacular as Interpreted by a Lawyer—An erecting contractor, who was building part of one of the great suspension bridges across the East River in New York, visited a law office and undertook to explain his troubles to a law student in the office. The would-be lawyer made notes and, confessing that he did not thoroughly understand the situation, made a report in substance as follows:

A Traveler was on the lower cord of the approach span of the Williamsburgh Bridge and was sustained by four Guys. Each Guy was held fast by two dogs, after passing through an opening in the tail piece. Tony, an Italian, had just been sent out and had given two of the dogs a fresh bite on the longest Guy, when they let loose, one of the Guys slipped, and the Traveler tipped over and threw the counter-weights into the air, and they went down on the street below and killed a man.—From an address by John C. Wait before the Civil Engineers' Society of Cornell University.

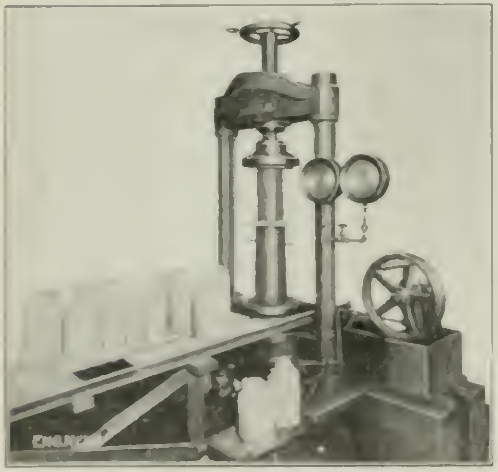
Type of "Pierce-Arrow" Motor Truck Used for Handling Hot Asphalt Paving Mixtures, Chicago, Ill.

Field Tests of Concrete for Municipal Work at Kansas City, Mo.

By F. S. [illegible]*

The early tests on concrete used in municipal work at Kansas City, included the usual tests on cement and sand but the tests on the large aggregate were confined to some very primitive investigations which consisted in making comparative mixes with different aggregates, placing them in similar molds, and at the end of certain periods, breaking them by striking repeated blows with a hammer. The quality was determined by the manner in which the concrete resisted the impact of the blows.

At best, this was a most unsatisfactory test and about a year ago the city started a systematic method of testing aggregate, and in fact, concrete, by taking samples of all concrete on the job and subjecting the samples to



[illegible] Compression Machine for Testing Concrete Cylinders Used by Kansas City, Mo.

compressive tests through periods up to one year. The city now has a 200,000-lb. hydraulic compression machine and one dozen 8x16-in. cast-iron cylindrical molds formed on a true surface. These molds are taken to the place where concreting is in progress, and without the previous knowledge of the contractor, the concrete is caught in a bucket as it is discharged from the mixer, and filled into the molds. No two molds are filled from the same batch, which possibly accounts for the wide variation in compressive strength of sets of cylinders at the same age. A [illegible] gas-pipe flattened at one end is used to tamp the concrete in the molds, and in tamping it [illegible] to make the cylinders as near like the concrete as it is deposited in the work as possible. [illegible] are noted.

The molds are allowed to stand until the concrete has set, usually from 12 to 24 hr. before removing to the laboratory, where the forms are taken off and the concrete cylinders are placed in a storage tank, which is kept filled with water at a temperature of about 70° F. The storage tank is a rectangular-shaped concrete box, 5x22 ft. in plan, 2 ft. 4 in. deep; it has a floor drain at lowest point for drawing off the water and a 3/4-in. perforated steam pipe runs the entire length of the bottom for heating the water in cold weather, as it is outdoors in an areaway.

The accompanying view shows the machine with a cylinder in position for crushing, and several tested cylinders in the foreground showing manner of fractures. It will be noticed that the openings between the uprights and the distance between platens of the machine is much greater than necessary for testing concrete cylinders, but it was so designed in order to make crushing tests (known as the knife-edge test) on sewer pipe up to and including 27 in. in size. The cast-iron stool saves using a long and cumbersome adjusting screw.

When making tests, a rubber plate about 1/4 in. thick is placed on the stool, the cylinder is set upon this, and another rubber plate placed on top. These plates are used to even up any irregularities there may be in the end surfaces of the cylinders and are believed to be superior to plaster of paris. The top platen, which is suspended from the adjusting screw on a ball-and-socket joint, is now screwed down firmly, and the load applied. As will be noticed, the machine is in reality a hydraulic jack, operated with a three-plunger hand-power pump, and the load is applied from underneath on the bottom platen.

Two gages are used; one is graduated in 50-lb. readings up to 10,000 lb., and the other is graduated in 500-lb. readings up to 200,000 lb. Each gage is equipped with a marker hand which registers the highest ultimate load attained. The load is applied at the rate of about 35,000 lb. per min.

As a rule the cylinders crush off at angles of about 45° on either top or bottom end, though some of them split from end to end into two or more prismoids. Observation has shown that concrete is quite green at 7 days, and is still improperly cured at 28 days. It would seem that much better results could be obtained from concrete if it were not subjected to live loads until after the 28-day period.

There is given also herewith a table of compression tests. As before noted there is a wide variation between tests of the same age, and complaint might be made against these discrepancies, but the writer has only attempted to make tests as near like the material used under working conditions as is possible, and no effort was made to obtain a concrete that would show uniformity in testing.

Contractors on city improvements are permitted to use any brand of cement they choose so long as it complies with the city's specifications, which are those of the American Society for Testing Materials, but it so happened that only three brands are shown in the table; they are standard brands of this district. A careful study of the chart will convince most readers that conditions and workmanship play by far the most important part in the manufacture of good concrete, and irregularities shown in these tests cannot be attributed to the cement.

In Test 12, cement "A" shows the highest results obtained, while Test 11 with the same brand of cement, same mixture, and same style of mixer, but by different contractors, shows the lowest. Test 5, cement "B," with

*[illegible] City Engineering Department, Kansas City, Mo.

17	11-12-13 p.m.	H	"	"	A	"	"	2-in. native, clean and uniform in size.	250 500 Avge. 375	1480 1620 950 1350	2150 1440 2500 2197	2720 1530 2125	Cloudy	65°	Sand was black and dirty looking. Aggregates fractured in 28-, 90- and 180-day tests.
18	11-20-13 p.m.	H	"	"	A	"	Quaking.	"	340 460 350 Avge. 383	800 550 650 667	1550 1400 930 1293	1440 1320 1400 1387	Clear	75°	A few aggregates fractured in 90-, 180- and 360-day tests.

Missouri River sand used in samples 6, 7, 8 and 10. Kaw River sand used in all others. Kaw River sand is coarse and sharp. Voids in loose sand = 32.2%. Compacted 29.9%. Missouri River sand is quite fine. Voids in loose sand = 31.6%. Compacted 27.0%. Quality of limestone aggregates in these tests was quite uniform. Aggregates marked "Crusher Run" include, from size indicated, to and above a No. 10 screen. Old concrete base aggregates referred to in tests Nos. 2, 3, 4, 5, 7 and 8 were made from Natural cement, the old mortar failed in each test, including the 7-day. Tests indicated that limestone aggregates seldom fail under 1400 lb. pressure per square inch. 360-day test on No. 1 (2070 and 2940 lb.)—avge. 2555 lb. 360-day test on No. 2 (1530 and 1410 lb.) average 1470 lb.

a 1:?:? mix and an aggregate of broken up old concrete made from natural cement shows an ultimate load of 1087 lb. per sq.in. in 184 days while Test 9, with the same brand of cement, a 1:2:4 mix and a $^3/_4$-in. native stone aggregate shows an ultimate load of only 1317 lb. per sq.in. at the same age.

A person may easily determine the thoroughness of which a batch of concrete is mixed by its looks, but our tests have demonstrated the foolishness of anyone attempting to judge its qualities by observation. A well graded sand and aggregate with hardly enough cement to hold them together, may be mixed so thoroughly as to look quite rich, while a batch containing plenty of cement, but with a [illegible] aggregate, and not so thoroughly mixed may appear quite "poor and lean." When the writer was taking sample No. 12, by observing the mixers, he considered it very poor and noted it accordingly, and No. 18 was noted as being very good, but actual tests have given results which were exactly the opposite, showing the uncertainty of trusting to observation alone.

It is believed that the 8x16-in. cylindrical molds are the best suited where aggregates of 1 in. in size or over are used, as this size permits the large pieces of aggregate to [illegible] well, and eliminates the arching effect which would [illegible].

There are no specifications requiring tests of the above [illegible] character, for the work, so far as has been experimented, and for the purpose of collecting data. The results obtained in [illegible] cases have been different from what were expected, and in some instances have been a surprise, yet it is felt that they have been more than paid for the trouble and expense.

The Sale of Bottled Mineral Water in the United States [illegible]

The Present Status of Small Cube Granite Block Pavements

As noted in the article on "Recent Developments in Granite Block Paving" in ENGINEERING NEWS, of Aug. 13, 1914, there is a growing tendency to reduce the size of granite paving blocks. Where specifications formerly called for blocks 7 and 8 in. deep, the present practice is to specify 4½ and 5 in. What is the minimum depth and size of blocks?

For durability 3½ in. of granite answers every purpose of 5 in., since wear is seldom appreciable on the surface of granite blocks in any pavement. For rigidity, the present practice is to depend upon a good portland cement concrete foundation and not upon the wearing coat, whatever its type. For a foothold for horses'

FIGS. 1 AND 2. VIEWS OF "DURAX" GRANITE BLOCK PAVEMENT, BROOKLYN NAVY YARD, NEW YORK CITY

feet and [illegible] the smaller the blocks and their arrangement in non-regular courses, the better the practical results. For cheapness, if the small blocks can be produced by machine at less cost than the larger hand-shaped blocks, the less stone will be required, and the cost of freight and haulage, which is a very large item, will be much reduced. As to noise, the smaller stone surfaces with asphaltic filler between appear to be less noisy than the present standard-size block pavement.

In the matter of adopting small granite cube pavements foreign practice has been much in advance of American practice. Small granite cube pavements have been used on German streets and roads for more than 20 years. They have been extensively used in many English and European cities. About [illegible] sq.yd. have been laid in Chile and about 1,000,000 sq.yd. in Argentina, South America, where a large percentage of the blocks are imported from Sweden and Norway as ballast for westbound ships.

In the United States, the first small cube or "Durax" pavement was laid in the Brooklyn, N. Y., Navy Yard in 1913 (Figs. 1 and 2). Since then pavements of this

type have been laid in Louisville, Ky., Cincinnati, Ohio, Columbus, Ohio, Troy, N. Y., Danville, Va., Salisbury, N. C., and contracts are pending in several of our large Eastern cities. During the year 1912 about 2,300,000 sq.yd. of "Durax" or, as they are known in Europe, "Kleinpflaster" pavements were laid.

"Durax" Pavement Construction—The common European practice for city streets is to bed the blocks evenly on 3/4-in. of stone chips, or sand, on a concrete foundation, the thickness of which is made to vary with the kind and density of traffic to be carried. After the blocks are placed, the joints are filled with clean stone chips and rammed to a solid bearing. After ramming, the joints are flushed with stone chips and poured full of a bituminous mixture heated to about 300° F. Enough mixture is used to fill the joints completely, making the pavement impervious. Cement grout filler may be used, but in this case the pavement is less elastic and more noisy. Finally, about 1/2-in. of sand is spread on the surface of the finished pavement and left to work into the joints.

On roads in suburban districts an old macadam base

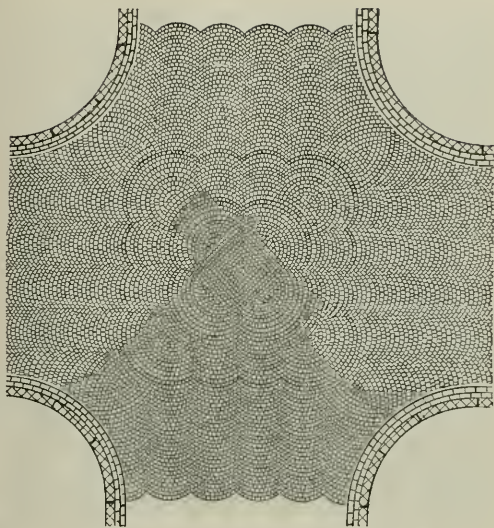

Fig. 4. Street Intersection Pattern, German Design

has been used successfully for a foundation. On these roads the blocks are laid on a 1-in. layer of sand and the joints are filled with sand only, after which the surface is wetted, rammed and rolled with a 5-ton roller. This gives a surface of the nature of a macadam road, but owing to the larger and hand-placed stone wearing coat it is, of course, more durable under dense or heavy traffic.

Ordinarily, the blocks are not laid in straight courses, but in an oyster-shell pattern (Fig. 3), that is in concentric interlocking segments of circles or diagonal courses. The advantage claimed for this method is, that the opposite wheels of a vehicle are not likely to be on the joints between stones at the same time, which reduces the jar and the subsequent wear and tear on the vehicle. A further advantage claimed is that this arrangement better distributes the wear on the pavement.

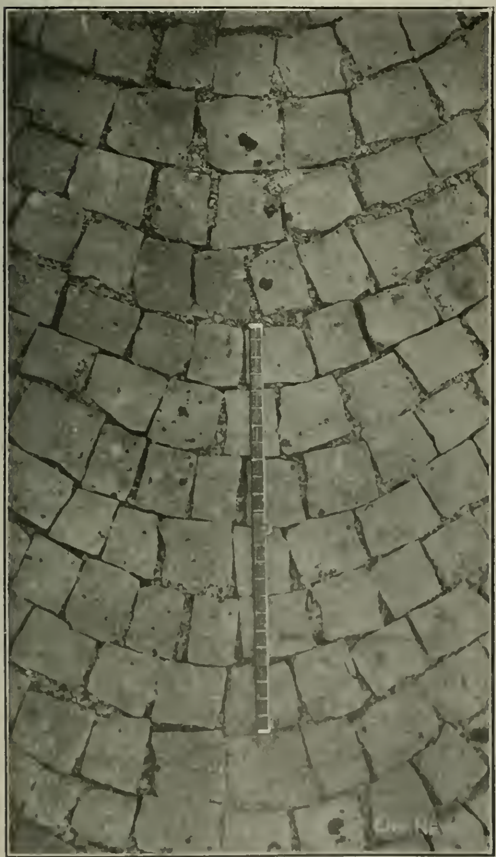

Fig. 3. Oyster-Shell Pattern for Laying "Durax" Blocks

American Experience

The specifications for the Brooklyn Navy Yard pavement provided that the "Durax" blocks should be irregular cubes, the edges to vary from 3½ to 2¾ in.; that the blocks should be laid in close contact with no joint exceeding 1/2-in. and in concentric interlocking segments.* The blocks under these specifications, were to show a compressive strength of not less than 30,000 lb. per sq.in., and a coefficient of wear of not less than 15 (French standard).

In Danville, Va., the cubes were of medium-grained granite 3½ in. to 2¾ in. in size. P. F. Brown, Assistant City Engineer, furnishes the following statement:

> We used machine-made "Durax" cubes (furnished by the Harris Granite Quarries Co., of Salisbury, N. C.). The pavement is bedded on a ¾-in. sand cushion upon a 5-in. concrete base, and is bonded with an asphalt paving filler (Texaco No. 39) using 2 gal. of filler per sq.yd.
>
> This pavement was laid by the city forces, using our regular block pavers. The cubes are laid in straight lines across

*See article in "Engineering News" Mar. 27, 1913, p. 629, "A Comparison of Recent Bids for Various Types of Paving in the New York Navy Yard," by Walter H. Allen.

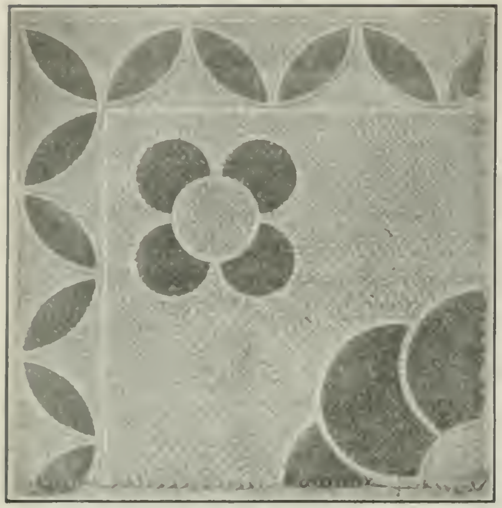

FIG. 5. STREET INTERSECTION OR COURT-YARD DESIGN; SHOWING POSSIBILITY OF MOSSAIC WORK

the street at right angles to the curb. The pavement cost $[illegible] per sq.yd., of which the concrete base (1:3:6 mixture) cost $[illegible] per sq.yd. It might be of interest to note that the labor account for laying "Durax," including preparing sand bedding and applying asphalt filler was $[illegible].24 per sq.yd.

This is an excellent pavement, giving a smooth waterproof surface, comparatively noiseless and free from dust, and on account of the smallness of the blocks furnishes an excellent foothold. We are well pleased and feel confident that it will prove most satisfactory.

The "Durax" blocks are generally more irregular in shape than the standard granite blocks now required for first-class city pavements, but being machine made can be turned out cheaper than the more perfectly shaped hand-cut blocks. Their cubical shape also gives the advantage that the most suitable one of the three depths may be used, which makes possible a pavement of fairly uniform thickness in spite of the irregular faces of the block.

REPAVING WORK—The $3\frac{1}{2}$-in. granite cubes are particularly adaptable for repaving city streets which have a good foundation left over from the former surfacing. The depth of the cubes being practically the same as wood blocks, brick and asphalt surfacing, the new surface may be placed without removing the old foundation or changing the grade.

POSSIBILITIES OF THE SMALL CUBE PAVEMENT—There are two points in pavements laid with small cubes which stand out pre-eminently. One, the ease with which warped and irregular surfaces may be paved in well rounded and pleasing curves, as is illustrated in Figs. 1 and 2 of the Brooklyn Navy Yard work. The other point is the possibility of artistic mosaic work in courts, public squares, etc., using different colored stones, as illustrated in the diagrams, Figs. 4 and 5, from the German journal "Die Strasse." While engineers, and perhaps especially highway engineers, are seldom interested in the esthetic points of construction, this is a point which will appeal to architects and city planning experts.

The small granite cube type of pavement is not patented. As noted before, it has been used in Europe for many years; but the extensive increase in its use in recent years is due largely to the method of manufacture by the Wern stone-cutting machine, which was fully described in ENGINEERING NEWS, Mar. 28, 1912, p. 614.

The First Water-Works in America are said to have been constructed in 1754 by Hans Christopher Christiansen to supply the Moravian settlement at Bethlehem, Penn. The water-works included a pump of lignum-vitae, of 5-in. bore.

Constructing a High-Pressure Gas Line to Louisville, Ky.*

By Lewis S. Streng†

The construction of a 12-in. steel pipeline for carrying natural gas from Inez, Ky., to Louisville—a distance of 180 mi.—presented many difficulties. The work was commenced Aug. 8, 1913, and completed and tested on Mar. 12, 1914.

The unusual difficulties of the undertaking were due largely to the nature of the country. The work on the Louisville end was simple compared to that in the mountains. Delivery of material was a problem. In some places, the nearest railway was 40 mi. distant, and the wagon roads hardly deserved the name. A team would start from Paintsville with two lengths of pipe, the load amounting to less than a ton, and return light, taking three days for the round trip. After 150 teams had made several trips, the roads were in miserable condition, requiring a repair gang to keep them passable.

On the Louisville section, much foreign labor was employed, but not back in the hills. The mountaineers drove the foreigners out of the country. The mountaineers were splendid workmen. They would walk four or five miles before daybreak, do a day's work and go back home with a lantern.

The steel pipe used was 12 in. inside diameter, 3/8 in. thick, weighed 45 lb. per ft., and averaged 20 ft. to the length or "joint" as it is called. Each joint was tested at the mill at 1000 lb. per sq.in. pressure and carefully inspected for defects. The couplings used were steel forgings of the familiar Dresser type, consisting of a central ring, two rubber-compound gaskets and two followers drawn up by steel bolts. Screw pipes were used in all river and creek crossings, with leak collars with rubber gaskets placed over each of the screw couplings, and over all this was bolted a heavy split-iron casting, or river clamp. Under all rivers, two lines were laid with valves and Y's at either end.

At railroad crossings, the pipe was placed in a 20-in. cast-iron casing, fitted with valves, on either side of the right-of-way. Eventually, a second line will be laid, with provisions for cutting out any section desired. In case of trouble, the check valve will prevent the escape of gas from the Louisville end.

Testing—The line was tested as laid before any of the couplings were backfilled. For testing purposes, two temporary compressor stations were erected, one on the Kentucky River, about 7 mi. above Frankfort, and the other on Mud Lick in Johnson County. The line was pumped up to 350 lb. per sq.in. pressure, and then carefully inspected for leaks. The excellent results obtained by this method were shown by a 48-hr. acceptance test of the whole line last February. At 350 lb. per sq.in. pressure, the leakage in 24 hr. was less than 1/4 per cent.

Construction Procedure—The construction force was organized in two divisions, one for the mountains and one for the Blue Grass, each in charge of a general superintendent. The headquarters of the mountain division was at Paintsville, with a territory to be covered of about 65 mi. The other division was about 115 mi. long, with headquarters at Lexington. Each division had two large gangs, with full camp equipment. These gangs started at the compressor stations and worked toward the ends of the divisions. In addition, each division had a special gang which installed the river, creek and railroad crossings. After more than half the work was finished, another gang was organized to hasten the completion of the work. The number of men in each gang varied from 200 to 500.

During the preceding summer, a survey had been made, and most of the right-of-way obtained. Stakes were set every 200 ft. and the first job of the construction gangs was to clear the right-of-way from 16 to 20 ft. wide. The digging crew then roughed out the trench, throwing the earth to one side; the other side being left clear for pipes. Where rock was encountered, a drill gang came next and the way blasted. After them came the graders, who trimmed the trench to proper dimensions, normally 18 in. wide by 36 in. deep.

Changes of grade up to perhaps 5° could be made in the couplings; but in general the straight pipe was laid at an even grade, and fire bends made where necessary. A small gang went ahead inspecting the pipes, dressing off any roughness at the ends, and making the necessary bends.

The pipe was then laid on skids over the trench and the couplings fitted. After a section had been finished, the lengths varying from 100 ft. to a half-mile, according to topography, the gang came back and lowered the pipe into the ditch.

Lastly, followed the backfilling gang. On level stretches, teams with drag-scrapers were used. On the slopes, breakers were built to hold the fill and leave the couplings exposed. Following the laying of the sections in the trench and their testing out, a small gang covered the couplings and trimmed up the fill.

The task of hauling material was a serious problem, as has been described, but that of stringing the pipes along the right-of-way was even more difficult. At convenient locations, the pipe could be unloaded where desired, snatch teams being added as required. Frequently, however, block and tackle were required. Five or six teams were sometimes needed to move a single joint.

On some of the trenching, gasoline-driven drag-line ditching machines were used. In good going, they could dig 2000 ft. of 18x36-in. trench in a day; but they were useless on grades, or where rock was encountered. They traveled very slowly and lost much time by necessary detours.

The best day's work reported by any of the gangs was about one mile of ditch. Occasionally, a pipe gang would report as high as 6000 ft. of pipe laid in a single day; in the rough country, 750 ft. was an average day's work. At times, when practically the whole trench was through rock, a gang of 200 men could not make more than 200 ft. per day.

*Extract from a paper presented before the Engineers' and Architects' Club of Louisville, Ky.

An Argument for Municipal Engineers—As street paving is without doubt one of the most important municipal functions, it is the plain duty of city officials to keep the pavements in good condition. We believe that if funds are not available for all of the city activities which are being assumed, that it becomes necessary for the city, as it would for a business firm or individual, to retrench; retrenchment should curtail those activities which are not primarily functions of municipal government, in order that those functions which are clearly the duty of the municipality may not be impaired. —Report of the Municipal Committee of the Cleveland Chamber of Commerce on "Cleveland Pavements," April, 1914.

Diaphragm Measurements of Water in Open Channels

By C. R. Weidner*

The measurement of large quantities of water, with a reasonable degree of accuracy, is a problem whose solution is often a laborious, expensive and time-consuming procedure. A device which will simplify the operation without decreasing the accuracy of the measurement was invented about nine years ago by Prof. Erik Anderson, of the University of Stockholm. It is termed the diaphragm or moving-screen method of gaging water. The method has been used in Europe with considerable success for the testing of turbines. Its accuracy, however, was not determined until recently, when the Swiss Bureau of Hydrography conducted a series of experiments for that purpose. The results of these tests showed a high degree of precision, and this article has been prepared with the object of bringing the device to the attention of American engineers.†

The diaphragm method of gaging is essentially a modification of the float method, in which the velocity is integrated over the entire area. Its use is, however, restricted to the measurement of water flowing in a channel of uniform cross-section. The apparatus consists of a diaphragm suspended from a car, which runs on a carefully lined and leveled track laid on the canal walls. The frame of the car and diaphragm is built of steel tubing or light angle iron; the wheels of the car are usually made of aluminum and run on ball bearings. The diaphragm frame is covered with oiled canvas or some light metal and pivoted about a horizontal axis in the direction of the current, so that it can readily be immersed or withdrawn without causing an appreciable rise in the elevation of the water surface. When a measurement of the velocity is being made a clutch holds the diaphragm in a vertical position. Figs. 1 and 2 show the rating canal and diaphragm in use at the J. M. Voith turbine-testing station, at Heidenheim, Germany. The cross-section of an installation at Notodden, Norway, is given in Fig. 4.

The method of procedure in obtaining a gaging is quite simple. A measured distance is first laid off along the canal walls. The diaphragm is then dropped into the stream at a point far enough upstream, so that it will have obtained uniform motion by the time it reaches the beginning of the measured distance. The diaphragm dips into the water quietly without disturbing the regimen of the stream. The time of transit over this distance is observed, from which the velocity of the diaphragm can be computed. The mean velocity of the water is usually assumed to be the same as the velocity of the diaphragm. A correction should, however, be made for the frictional resistance of the car, and for the velocities in the clearance between the diaphragm and the periphery of the canal, which are not integrated by the diaphragm. In well designed apparatus this frictional resistance and the clearance are so small (usually about ½ in.) that no serious error is caused by neglecting their effects, especially since they have a tendency to counteract each other on account of the smaller velocities occurring near the periphery. To obtain the discharge the cross-sectional area of the water must be known; the depth of water in the channel is, therefore, constantly observed during a gaging.

The chief advantage of this method is the rapidity with which the measurement can be made. This is of importance especially in the testing of turbines, where it is rather difficult to keep operating conditions constant for a time sufficient to obtain a good current-meter measurement. In testing turbines installed at power stations, weir measurements are often impracticable on account of sacrificing part of the available head, and current-meter gagings, although the least expensive, require skilled observers, an accurate rating of the instrument and considerable time in computing the discharge. A complete diaphragm gaging can be made in a few minutes and the result computed immediately.

†This method of measurement was [illegible]

Fig. 3 shows the schematic arrangement of an electrical recording device used in conjunction with the diaphragm at the J. M. Voith station at Heidenheim. K_1, K_2, K_3 are three electromagnets; pens L_1, L_2, L_3 are attached to the armatures of these in such a way that a break in the line traced on a moving chart, occurs whenever the circuit is closed. Next to the rail A, on which the diaphragm car runs, an electric circuit P has been arranged with 11 contact points spaced 1 meter apart. The battery N_1 and switch O_1 are connected in series with the

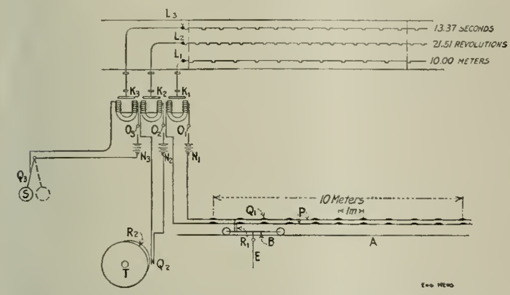

FIG. 3. WIRING DIAGRAM OF RECORDING APPARATUS AT HEIDENHEIM

electro-magnet K_1. When the shoe R_1 on the car B passes over the contact points Q_1, the circuit is closed; this fact is shown on the paper by a break in the line traced by the pen L_1. A similar arrangement is used to record the number of revolutions of the turbine. The eccentric R_2 on the turbine shaft T closes the circuit Q_2, and the pen L_2 records a break in the line for each revolution. The third pen L_3 is connected to the time circuit, every half-second being recorded on the chart. With a similar recording device used at the Berlin Technische Hochschule, two additional pens actuated by floats record the elevations of the water in the head- and tail-races.

The discharge at the Voith testing station was formerly measured by current meters, as the head was too small to permit the use of a weir. The current-meter gaging took from ½ to ¾ hour and if one considers that several measurements of the discharge must be made for a complete turbine test, it may readily be seen what a saving in time the diaphragm method accomplishes.

The disadvantages of the diaphragm method are that a channel of sufficient length and uniform cross-section must be available, and that the cost of installing the necessary apparatus is rather high. A diaphragm and its appurtenances installed at the hydro-electric plant at Ackersand, Switzerland, cost approximately $580, which includes the recording apparatus. For these reasons, the method is limited to the measurement of moderately large quantities of water, and its application will probably be restricted to hydraulic laboratories, turbine-testing stations, and places where the apparatus can be used often and first cost is, therefore, not such an important factor. For high-head power plants or small low-head plants, the installation of the diaphragm apparatus would be of considerable commercial importance, inasmuch as the operating efficiency of the turbines could be obtained at all times with a few simple measurements.

The new method could also be applied to discharge measurements in the main canals of irrigation systems, for the successful operation of which the measurement of the water is essential. It is not likely that any device can supersede the weir, for the measurement of the flow in small laterals; but for the larger canals the diaphragm method possesses advantages which in some cases would make its use preferable to either the weir or current meter. In many channels there is not sufficient fall to permit the use of a weir, and in others the silt-bearing streams affect its accuracy. Rating flumes could easily be calibrated and a recording device installed to give a record of the total flow.

Professor Andersson has used the method extensively in the Scandinavian countries for testing turbines at power plants; and in places where a suitable canal was not available a wooden flume was built. Wherever possible, a length of from 50 to 100 ft. was chosen for the rating flume, but in some cases it was possible to get a length of only 33 ft. The actual gaging distance was then only from 10 to 13 ft. Where the car and track were not available, the diaphragm was guided by wooden strips in the passage over the gaging distance. Some of the canal sections were quite large, as quantities as high as 830 cu.ft. per sec. have been measured.

Diaphragm measurements are subject to the following errors: (1) in observing the time of transit; (2) in observing the depth of water; (3) in estimating or neglecting the frictional resistance of the car; (4) the velocities in the clearance; (5) the wind pressure on that part of the apparatus not submerged; (6) the possibility of the diaphragm rubbing against the periphery of the canal;

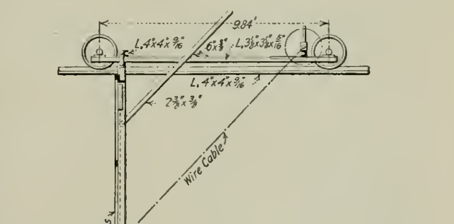

FIG. 4. CROSS-SECTION OF DIAPHRAGM AND CAR USED AT NOTODDEN, NORWAY

(7) foreign matter becoming wedged between the diaphragm and periphery.

As previously mentioned an extensive series of experiments* was made by the Swiss Bureau of Hydrography to determine the accuracy of the diaphragm method by

*The details of these experiments will be published shortly in a bulletin of the University of Wisconsin, abstracted from "Vergleichs-Versuche mit Flügel und Schirm-Apparat zur Bestimmung von Wassermengen," by Otto Lütschg, Adjunkt der Schweizerischen Landeshydrographie, Bern, Switzerland. Price, 1.50 francs.

comparison with weir and current-meter measurements. The results of these experiments may be summarized in the following conclusions:

(1) The diaphragm gagings checked the meter gagings in all cases within 1%; the discrepancies being in some cases positive and in others negative. (2) The diaphragm gagings checked the weir gagings in all cases within 3%. (3) The rating canal for diaphragm gagings should be of sufficient length to overcome the effect of pulsations in the stream. (4) The diaphragm should be placed in a vertical position in making a gaging. (5) The diaphragm method of gaging will give equally good results with perturbed flow as with parallel flow.

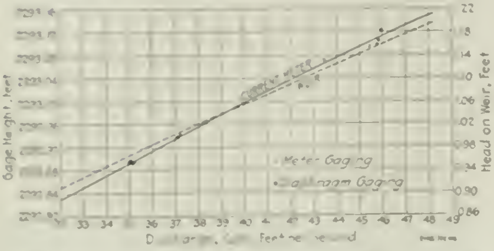

FIG. 5. COMPARISON OF SIMULTANEOUS DIAPHRAGM AND CURRENT-METER GAGINGS

In these experiments the current-meter gagings were considered more accurate than the computed weir gagings, because the weir was not of standard form and it was difficult to select the proper coefficients. The results of the different gagings have been plotted and are shown in Fig. 5. The solid curve represents the average of the plotted meter gagings; while the dashed curve is the computed weir-discharge curve. From this diagram it can be seen that the diaphragm gagings check the meter gagings very closely. The differences range between such small limits, that for most practical purposes they are of no significance. Theoretically, the results of the diaphragm gagings should be too small rather than too large, as the velocity of the diaphragm is retarded by the frictional resistance of the car, for which no correction was made. It seems, however, that the effect of this resistance is offset by the smaller velocities existing in the clearance between the diaphragm and the periphery of the canal, which are not measured by the diaphragm.

The application of the diaphragm is obviously limited; but no one method will apply to all situations. Past experience with the diaphragm in Europe has been very satisfactory; and it will undoubtedly come into use in this country, where suitable canals are available and the cost of installation is not too great. In view of its advantages and accuracy, the diaphragm method deserves recognition as a valuable contribution to the science of hydrometry.

Rigid Overhead Conductors for Electric Traction, Michigan Central Terminal, Detroit

The Michigan Central Tunnel under the Detroit River at Detroit, built in 1910, is equipped for electric traction with bottom-contact third-rail identical in form and arrangement with that used in the New York Central terminal at New York City. The same equipment was extended into the new terminal yard and station about a mile west of the tunnel, completed a few months ago. However, some special requirements in the east approach to the station called for various short sections of overhead conductor, and in the trainshed of the station overhead conductor is used exclusively. The conductor-rail potential is 660 volts.

A rigid-conductor overhead system was designed for these uses. It is working satisfactorily, and while relatively high in cost it appears to be an excellent solution of the problems of the case.

RIGID SUPPORTS—In the trainshed, which is of the low-roof type, the rigid overhead conductor-rail is supported by hangers bolted direct to the roof framing of the trainshed. In the yard, transverse bridge supports were built at intervals of about 100 ft., spanning one, two or three tracks as required. The bridges are similar to signal bridges, or to the bridges used for cable overhead work in such systems as that of the New York, New Haven & Hartford electric zone (New York, N. Y., to New Haven, Conn.). The bridges support longitudinal trusses, one over each track, and to the bottom chords of these trusses are attached transverse beams to which the conductor-rail supports are bolted.

The relative arrangement of track and bridges is indicated by the sketch, Fig. 1, showing in plan a part of the east station approach trackage.

FIG. 1. PART OF UNDERGROUND TRACKAGE IN EAST APPROACH OF MICHIGAN CENTRAL TERMINAL, DETROIT

CONDUCTOR-RAIL AND HANGERS—While the third-rail (at track level) is a 70-lb. bullhead rail, the overhead conductor is a 30-lb. T-rail of standard rail section, though of special composition. It is held in two-piece porcelain insulators engaged by hanger straps which fit in T-notches in the sides of the insulator. The details above the insulators vary with the nature and position of the supporting structure. Several typical hanger constructions are grouped in Fig. 2.

CONDITIONS REQUIRING OVERHEAD CONDUCTOR—The crossovers in the approach tracks, though laid out for No. 8 frogs, involve a gap between facing ends of third-rail of as much as 90 ft. On the westbound or upgrade tracks, where the gradient is 1% and over, so long a period of no current-supply to a train (using a single locomotive-long gaps in the power-supply as prevail in the upgrade tracks of the east approach; the gradient at the east end of the trainshed is 1%, and a large part of a train would still be on the heavy grade (hence requiring heavy power) while the locomotive was on the crossover. Therefore, the addition of the crossovers led to providing overhead conductor at the crossovers, and for simplicity and to eliminate any chance of men or tools getting in contact with conductor rails in the care and inspection of cars and interlocking equipment, the overhead system was adopted for the entire length of all the trainshed tracks, eleven in number.

J. C. Mock, Electrical Engineer of the Detroit River Tunnel Co., was in charge of the design of this equipment, under George H. Webb, Chief Engineer.

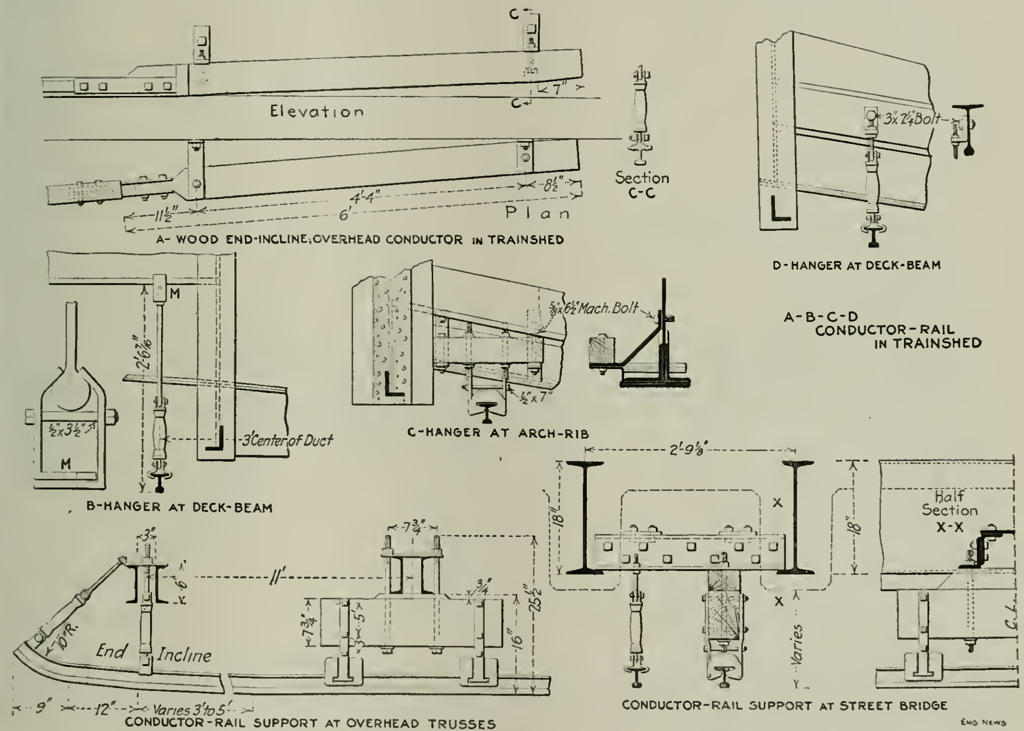

FIG. 2. OVERHEAD CONDUCTOR-RAIL HANGERS IN APPROACH AND TRAINSHED OF MICHIGAN CENTRAL TERMINAL, DETROIT

unit) would produce enough retardation of the train to bring about harmful jerking when the shoe makes contact again. On this account, it was considered essential to provide overhead conductors for bridging the gaps. No such conductors are provided on the eastbound or downgrade tracks, or on the west side of the station, where the gradient is only 0.23%.

In the trainshed, the use of third-rail (at ground) was contemplated at first. This was on the basis of continuous unbroken tracks through the shed. But later, for convenience in handling trains, crossovers were laid between the pairs of tracks at midlength of the trainshed. These introduce the same considerations in the matter of

Paying for City Street Pavements—An investigation of the methods in vogue in 50 large American cities of paying for pavements has been made by a committee of the Cleveland, Ohio, Chamber of Commerce. The results are as follows:

New Paving—

In 62% of these cities the property pays all.
In 6% the property pays 50%.
In 10% the property pays more than 50% and less than 100% except in one city where the property pays 30%.
In 22% of these cities the city pays all.

Repaving—

In 42% of these cities the property pays all.
In 10% the property pays 50%.
In 8% the property pays between 50% and 100%.
In 40% the city pays all.

Approximately 25% of the cities pay the major part of the original paving, while 40% of the cities do the major part of repaving.

The Seros Hydro-electric Development near Lerida, Spain

Regulating Reservoirs, Earth Dams and Power House

By J. C. Stevens*

SYNOPSIS—The diversion dam, canals and gates of the [illegible] hydro-electric development at Seros, near Barcelona, Spain, were described in the previous issue. The present article is complementary, describing the seven earth dams which create the four regulating reservoirs, together with the power house.

Regulating Reservoirs

The water withdrawn from the River Segre near Lerida for the hydro-electric plant near Seros is led through some 17 miles of canals, the construction of which has already been described. About three miles before reaching the power house, the canal line crosses a series of low valleys, seven of which were closed by earth dams to create four regulating reservoirs. The arrangement of these is shown in the general plan (Fig. 1).

The embankment for Dams 1, 2 and 3 were made largely from borrow pits excavated by steam shovel and by standard graders, the former working in borrow pits on the hill sides above water line of the reservoir and the latter in the beds of the "barrancos" upstream from the dams. The remaining dams were made by slip, wheel scrapers, carts or push cars in a manner to best suit the local conditions of each. About one-half of the total earth embankments were taken from the canal section. Steam rollers were used on Dams 1, 2 and 3, but on the others a smaller roller, drawn by mules, was used. This roller was made of a series of cast-iron disks or wheels, with faces about 1½ in. wide. They were fixed on parallel axles and interlocked to keep the wheels from clogging with mud. The bed could be loaded with stone to any desired weight.

Fig. 1. Regulating Reservoirs, Lower Canal, Station and Tailrace

Dams

The following table gives general quantity data for each of the earth dams:

Dam No.	Maximum height, ft.	Maximum width of base, ft.	Length of crest, ft.	Cu. yd. embankment	Sq. yd. paving
1	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
2	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
3	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
4	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
5	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
6	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
7	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Total				[illegible]	[illegible]

In Fig. 2 is shown plan and cross section of Dam 3, the largest of the group. The same general design is followed for the remaining six.

The cut-off trench on Dams 1 and 2 was excavated about 4 ft. deep in the bed of the valley, and then a row of steel-sheet piling was driven in the bottom of the trench to refusal. Some of these penetrated to a depth of 12 ft. The trench was then back-filled with puddle, inclosing the upper end of the steel sheeting.

On the canon sides, the cut-off trenches were refilled with puddle as the dams were raised. Where the trenches cut the horizontal rock strata of the canon sides, keys were built into the rock that also projected well into the puddle, forming a sort of cut-off collar to break the seepage plane along the faces of the rock strata. These keys are shown in Fig. 2.

The foundations of all dams were well stripped of all vegetable matter and the portion under the "B" section

*[illegible]

was excavated 1½ ft. minimum, to insure a good bond with the original ground.

Outlet pipes were laid in trenches excavated in the original ground at the sides of the cañons under Dams 1, 2 and 3. These pipes were 1.0 m. diameter, made of 6 mm. steel plate, riveted in 6-m. lengths, and joined by heavy cast-iron flanges bolted together. The trench was then refilled with concrete, leaving a minimum thickness of 20 cm. around the pipe. A large cut-off collar surrounds the pipe at the point where it crosses the puddle trench, and smaller collars project from the concrete at each joint of the pipe. Above the concrete, the trench was refilled with clay and gravel puddle, which joined with the earth embankment of the dam.

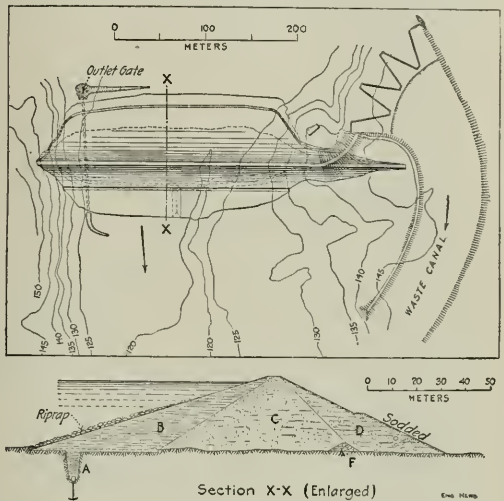
At the upper end of the pipes is a reducer section and a gate valve, 80 cm. diameter, operated by a torsion shaft with the mechanism on top of a tower frame.

The first reservoir is formed by Dams 1, 2 and 3. The connection between Dams 2 and 3 is an unlined channel 40 m. (131.2 ft.) wide on the base, with side slopes roughly ½ on 1, the bottom being level. The second reservoir is formed by Dams 4 and 5, the connection between them being an unlined canal with bottom width 18.0 m. (59.06 ft.) and side slopes 1 on 1. The third reservoir is formed by Dam 6 and the fourth by Dam 7. No spillways are provided for the second, third and fourth reservoirs, but a spillway at the left end of Dam 3 (Fig. 2) will provide a discharge capacity of 296 cu.m. per sec. (10,000 sec.ft.) under 0.65 m. (2.25 ft.) head. This is of the "zigzag" type, 304 m. (997 ft.) long, and operates entirely on freeboard. A discharge channel with 300 cu.m. per sec. capacity discharges the water into the cañon below the dam. This spillway will not come into action except in the case of an unprecedented flood on the drainage area above the dam, coincident with the stoppage of the power canal. The power canal has sufficient capacity for all known floods.

Filling Reservoirs and Testing Dams

The filling of the reservoirs was attended with some settlement, and consequent cracking of the earth dams. The seepage for each was carefully collected and measured over Cippoletti weirs, readings being taken every two hours. The total seepage from all of the seven dams did not exceed 3.0 sec.ft. with reservoir full. The seepage increased uniformly with the head, but whenever the head remained stationary, there was noticed a tendency to decrease.

Little or no seepage occurred through the dams themselves, but nearly all of it occurred in the horizontal strata of porous rocks that are exposed in the side of the cañons. Seepage through these original hillsides could not be prevented. In some cases the seepage appeared below the dam, in some it came to the surface within the section of the dam near the back side. Where this occurred, deep trenches were dug into the hillside, following the toe of the embankment, with spurs where necessary to intercept the water. These trenches gave an easier outlet for the water and prevented saturation of the earth embankment. They were refilled with large, broken stone of a uniform size to prevent caving. The rock dike, Fig. 2, answered its purpose of a blind drain, and in nearly all cases water began to weep from them after the reservoirs were filled. The greatest seepage occurred from Dam 1. A spring of crystal-clear water developed from the outlet of the rock dike, that runs about 80 gal. per min. with the reservoir full. The water undoubtedly came from the cañon side and followed the rock dike to its outlet at the lowest point of the valley. The remainder of the seepage came from the horizontal rock strata in the cañon sides except a small portion that appears as ground seepage in the valley below



The materials designated by letters in the cross section are:

CLASS A—Puddle refill of the cutoff trench; equal parts of clay and bank gravel in which all stones over 1 in. diameter were rejected. Clay and gravel hand mixed at the side of the trench and shoveled into it, thoroughly mixed with water and compacted by tampers.

CLASS B—Natural bank clay, free from stones larger than 2 in. diameter, spread in 8-in. layers inclined at about 3% towards the upstream face of the dam, sprinkled and rolled.

CLASS C—Borrow run earth, or clay and gravel of coarser material than Class B. In placing the finer and more compact material was placed in the upstream portion. To accomplish this the "C" section was divided into four equal parts and the limiting sizes and quantity of stones were fixed in each quarter in such a manner as to secure as far as practicable a gradual decrease in the imperviousness from the front to back faces of this section without sacrifice of density.

CLASS D—Borrow run of coarse material, on earth and gravel with larger stones intermingled and spread in layers of about 30 in. with only sufficient rehandling to insure a dense mass and at the same time pervious to water filtration.

CLASS F—A rock dike built transversely across the dam near the lower face to act as a blind drain to relieve any filtration that may penetrate the face of the dams.

Fig. 2. Earth Dam No. 3, Seros Project

the dam. A trench was dug along the entire length of the toe of this dam, and all saturation of the body of the dam effectively prevented in this manner. The total seepage from the dam is 30 liters per sec. (1.05 sec.-ft.) with reservoir full.

Transverse settlement cracks developed along the shoulders of the embankment on all dams. These cracks continued to widen from a hair crack to about 1½ in. wide in some cases, and then appeared to remain stationary. They were sealed by drilling 3-in. holes along the crack and refilling with a liquid clay puddle.

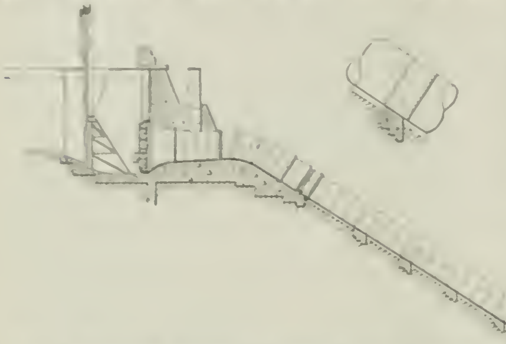
Dam No. 3, which will take its place among the high earth dams of the world, showed very little settlement and comparatively little seepage. The total seepage with reservoir full was 0.64 sec.-ft., all of it coming from the rock strata in the original hillsides.

It is next to impossible to build an earth dam that will not leak, and as long as the seepage water remains clear there is no apprehension. To have completed seven

earth dams on one project in which the combined leakage is less than 3 sec.-ft., or 1 part in 1000 of the flow from the reservoir, is a source of no little satisfaction to the writer.

Generating Station

The power house is provided with four 16,000-hp. Francis-type turbines on vertical shafts, each direct connected to a 10,000-kv., 50-cycle, three-phase alternator generating at 6000 volts and revolving at 250



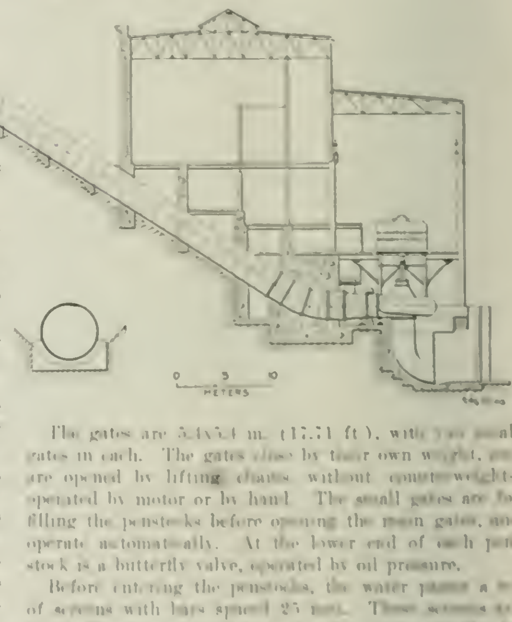


Fig. 3. Sections through Power House, Penstocks and Forebay

r.p.m. Room is left for a fifth unit of similar dimensions. The maximum head is 49.5 m. (162.5 ft.) and the minimum 46.0 m. (151 ft.). Excitation is secured by two 600-hp. 600-r.p.m. turbines direct connected to 300-kw. generators, or by a motor-generator set. Current is stepped up from 6000 to 110,000 volts in the transformer house, which is built as a portion of the main station.

The substructure is massive concrete and includes the anchor block for the penstocks and the foundations for the turbines. The latter have their draft tubes formed in the solid concrete. The generator floor, walls, crane tracks, roof trusses and inside steel work are supported by structural steel columns. The walls and partitions of the superstructure are of local brick. The roof is a 5-in. concrete slab, laid on ribbed metal and waterproofed with asphaltum. Some of the floors were also of concrete slab with ribbed metal and plain round steel-rod reinforcing, but the greater portion are of concrete supported by brick arches resting on the I-beam flanges of the floor system. The Spanish masons are very adept at building the brick arches, a single board cut to the span and rise desired serving them for centering forms. An 80-ton crane traverses the generator room and a 20-ton type runs over the transformers. There is the usual machine-shop equipment.

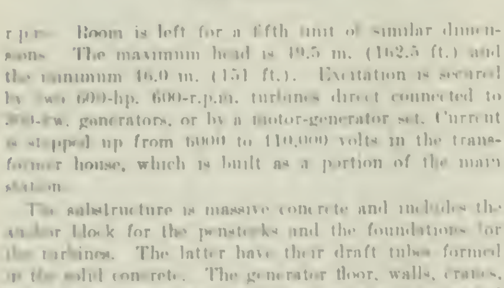

Fig. 4. Power House Exterior, Showing Forebay

The penstocks for the four main units are of 10-cm. (3/8-in.) steel throughout, 3.0 m. (9.84 ft.) inside diameter, equipped with expansion joints, just beyond the upper elbows, which are anchored in the forebay wall. The lower elbows are imbedded in an anchor block, integral with the general foundations. The reducing section and gate for the fifth unit have been installed. The exciter penstock is 1.2 m. (3.94 ft.) in diameter, anchored similar to the main penstocks. At the lower end it divides into two branches and supplies water for the two exciter turbines. Each penstock is provided with a vent pipe just below the gate, that extends 1 m. above high water in the forebay.

The gates are 5.4x5.4 m. (17.71 ft.), with two small gates in each. The gates close by their own weight, and are opened by lifting chains without counterweights, operated by motor or by hand. The small gates are for filling the penstocks before opening the main gates, and operate automatically. At the lower end of each penstock is a butterfly valve, operated by oil pressure.

Before entering the penstocks, the water passes a set of screens with bars spaced 25 mm. These screens are in duplicate, each being suspended independently by lifting chains running over a chain block, by means of which one screen may be removed for cleaning while the other is in service.

The entire project was built very quickly. Active work began in January, 1913. Water reached the forebay on Mar. 10, 1914, or 15 months thereafter. The construction of the project involved the quantities shown in the following table:

Right of way	717 hectares = 1800 acres
Excavation exclusive of borrow for dams	[illegible]
Embankment in dams	[illegible]
Structural steel	[illegible]
Concrete and masonry	[illegible]

Turbines and penstocks were furnished by Escher Wyss & Co., of Zurich, Switzerland; the various gates and gate mechanisms were from Ransomes & Rapier, Ltd., of London; racks and screens came from Aumund Gerecke & Komagen, of Zurich. The electrical equipment was made by the General Electric Co., of Schenectady, N. Y.

U. S. A. Practically all of the steel was furnished by the Blaw Steel Construction Co., of Pittsburgh, Penn., U. S. A.

The work was carried out by the Ebro Irrigation & Power Co., Ltd., under the supervision of the Pearson Engineering Corportion, Ltd., of New York. The following are the officials in charge of the work: F. S. Pearson, President; A. W. K. Billings, Vice-President and Managing Director; Fred W. Abbot, Manager of Construction; J. A. Sargent, Chief Engineer. The work was executed under the inspection of the Public Works Department of Spain, Sr. Don José Bores, Chief Engineer for the Province of Lerida.

A Dangerous Piece of Subway Construction

Building the Boylston Street subway in Boston* past a poorly founded church tower, the Old South Church, cor. Dartmouth and Boylston St., was described a short time ago by L. B. Manley before the Boston Society of Civil Engineers, the work having been successfully completed. Prior to this, the operations at Old South Church have been withheld from publicity, the engineers of the Boston Transit Commission apparently having in mind the chance of a bad accident.

The stone tower adjoins the church and is continuous with its masonry; it is a rectangular prism, 25x28 ft., with turrets and a stubby spire, 231 ft. high above sidewalk. It stands within 20 ft. of the street line. The Copley Square Station of the subway comes right opposite. Although the northerly station platform is omitted along the church, and though the subway itself was crowded over to the opposite (south) side of Boylston St. as far as possible, the subway comes within 27 ft. of the tower foundation, and within about 35 ft. of the tower itself. The tower rests on a spread footing, 37x42½ ft., of granite, supported on piles.

The subsoil here is filled material for about 20 ft. below sidewalk level, resting on 90 to 100 ft. of silt and clay, with pockets of sand and gravel in its upper 16 ft. The piles on which the church tower rests were driven into this stratum and were cut off about 6 ft. above the bottom of the fill, or about 15 ft. below sidewalk level. The bottom of the subway structure is 30 ft. below sidewalk, or about 15 ft. below the base of the tower foundation masonry. The double-track subway structure and station integral with it are a reinforced-concrete structure designed strong enough to distribute its load uniformly over its base area, so as to avoid the possible difficulties of a pile foundation.

The church tower (with foundation) is estimated to weigh 5000 tons, giving a uniform base pressure of 3.8 tons per sq.ft. However, shortly after the completion of the tower in 1875, it started to lean toward the street, finally attaining a maximum lean in the direction of the corner of about 3 ft. This increases the pressure in the lower corner of the foundation. With a 30-lb. wind in the same direction, the greatest soil pressure under the tower at the leeward corner nearest the street would be over 5 tons per sq.ft. The number and length of the piles are not known, but in any event the pile loading is greatly excessive. Under these circumstances, there was good reason for fearing that the subway excavation, only 27 ft. away, and 15 ft. below the bottom of the masonry, might start a soil movement which would threaten disaster.

A reassuring feature is the fact that in this whole region there is direct evidence that the ground has subsided or shrunk vertically to an amount of from several inches up to 2 ft. The indications are that this is due to a compression and settling of the great depth of silt. If the leaning of the tower could be charged against this same effect, there would be no reason to assume the tower foundation to be weak.

The Boston Transit Commission prescribed in detail the method of construction to be followed at the Copley Square Station, and assumed the responsibility for the safety of the tower if its prescriptions were followed.

It was decided not to try to underpin the church tower, but to depend upon the old foundation and conduct the subway work in such a way as to prevent any possible movement of earth. The essence of the method was building the subway in successive transverse slices, 12 ft. long in the direction of the subway, each fully sheeted, one slice of the subway structure being completely built before the next slice ahead was excavated more than 10 ft. Steel sheeting around the slice was driven before excavation, and this sheeting in turn was stiffened and supported by constructing a "self-supporting" concrete back-wall against the inside of the sheeting in a narrow trench. The back-wall and the sheeting were always driven and built half a slice ahead, and the back-wall being reinforced with horizontal rods, it had support at its rear end against the finished subway structure and at its forward end against the 5-ft. section of trench in which it was built; in addition, the wall was fully braced across the width of the subway excavation. Immediately upon completing the general excavation of a slice, the floor was surfaced off with concrete, waterproofing placed, the permanent reinforced-concrete floor constructed and then the side walls, columns and roof beams placed, and concreting completed.

Extensive grouting of the subsoil was done in connection with these operations, both before beginning excavation and after completion of the subway. Preliminary to the general excavation, the westerly end of the work was inclosed by a cutoff wall of steel sheeting on the line of Dartmouth Street, and the portion west of this line (i.e., in front of the church) was grouted with cement; grout forced in through 2-in. pipes jetted into the clay every 5 to 10 ft. The air pressure used for grouting was generally 50 lb. (90 lb. proved too high).

After completion of the subway structure, the space back of the longitudinal line of sheeting nearest the church was also grouted as thoroughly as was possible, in order to consolidate the soil near the church tower foundation and fill any voids that might have been created.

The subway construction progressed quite rapidly under the circumstances; the average time for constructing one 12-ft. slice, after work was fairly started, was seven days. The dangerous section was completed by December, 1913.

The tower increased its lean by about 1 in. during the operation, measured at a point about two-thirds of the height of the tower from the street. A settlement of ½ in. of the lowest point was noted.

*See article "New Subway Construction in Boston," "Engineering News," Dec. 11, 1913, pp. 1190-1192.

Concrete Lining, Franklin Canal, Rio Grande Project

By L. M. Lawson*

By Act of Congress, the benefits under the Reclamation Act were extended to the State of Texas. The Franklin Canal, which has been in existence for a number of years, was purchased by the Reclamation Service, to be reconstructed and enlarged and become the main canal to serve the 15,000 irrigable acres in the El Paso Valley. On the completion of the Elephant Butte Storage Dam, the total area to be irrigated under the entire project will be 180,000 acres, of which 20,000 lies in the Republic of Mexico. The Franklin Canal has its intake just above a concrete diversion dam in the Rio Grande near the city of El Paso. From this point it follows at the base of a steep slope along the river for one mile, passes through the lower portion of the city of El Paso on Eighth St. and continues through the central portion of the valley, a distance of 15 miles. Its maximum capacity, when purchased by the Government, was 100 sec.-ft. and approximately 12,000 acres were in limited cultivation under the irregular supply from the natural river flow.

The intake structure, the diversion dam, alignment, the bridge crossings and general condition of the canal were inadequate for the irrigation of any increased area and temporary structures would cost in maintenance, in a short time, more than permanent concrete structures.

The reconstruction plans proposed a new intake at the end of the diversion dam; a settling basin with sluice gates to discharge the heavy sand into the river; lining with concrete the portion along the river bank, and providing a rubble wall for river-protection; lining the 6000-ft. section through Eighth St., El Paso; the enlargement of the earth section below the city, and providing necessary concrete and timber and steel bridges and structures. With this enlargement it would be possible to divert 150 sec.-ft., permitting the area under cultivation to be increased from 12,000 acres to 15,000 acres.

The lining on Eighth St., which will be considered first in this article, was decided on as necessary in order to discharge the increased quantity within the right-of-way (25 ft.) granted by the city. The franchise provision, taken over with the canal when purchased, made it possible for the city authorities to enforce covering the canal through the city limits. To overcome this objectionable feature, a new franchise was submitted and passed, which specified certain bridge and fence work in lieu of the cover. The old earth-lined canal occupied 44 ft. of the 70-ft. street and was crossed by five steam railways, two electric roads and three wooden street bridges. There were also 11 sewers crossing the canal bottom from 6 in. to 3 ft. above bottom grade.

The plan of cross-section adopted, permitted the greatest width of roadway on either side, and it is the intention of the city authorities to park and otherwise improve the remaining portion of the street. Soil and drainage conditions permitted a 1½ to 1 side slope of the lined section on Eighth St., the 4 in. of concrete being placed with forms. In the settling-basin section, the side slopes were 1 to 1, with the concrete placed without forms. On account of the narrowing of the section (see Fig. 1, Sec. 4) and the low elevation of the banks of the old canal, forms

CONCRETE-LINED CANAL, RIO GRANDE IRRIGATION PROJECT, EL PASO, TEX.
[illegible]

*Assistant Engineer, Rio Grande Project, U. S. Reclamation Service, El Paso, Tex.

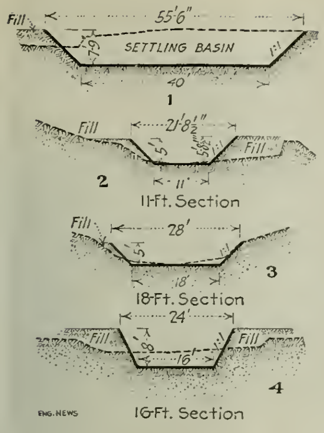

FIG. 1.

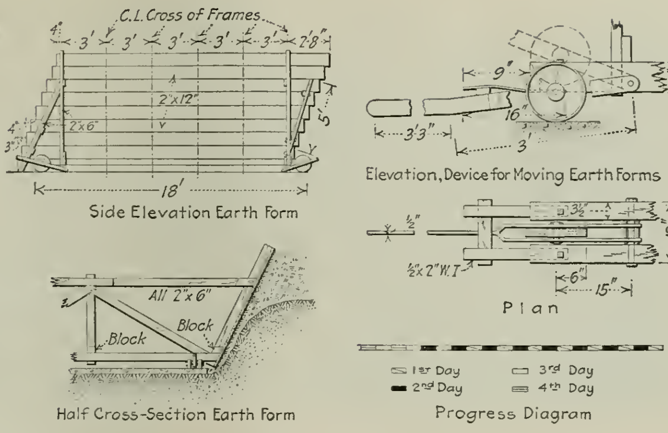

FIG. 2.

FIGS. 1-3. SECTIONS OF FRANKLIN CANAL, RIO GRANDE IRRIGATION PROJECT, AND DETAILS OF EARTH AND OF CONCRETE FORMS

were devised to permit the earth being tamped in place before concrete was poured. The procedure on the Eighth St. section was as follows: The bottom was excavated to the new grade, which in most cases was from 12 to 20 in. lower than the original grade. The sides were then trimmed roughly to line with slip scrapers, depositing the earth within easy reach to facilitate the back filling. The 4-in. concrete floor was then laid.

The earth form (Figs. 2 and 4) was then placed on the floor. This form weighed about three tons and was built to the outside lines of the concrete and could be easily lined up on the concrete floor. On each corner there was a steel lever and wheel. By lowering this lever the weight of the form was placed on wheels, which permitted the form to be rolled along on the concrete floor to the next position. When in the right position the levers were raised and the form allowed to rest on the concrete floor in position for back filling and tamping. The earth in most places was a light sandy loam, which, after being sprinkled and tamped, remained in place very satisfactorily (Fig. 5). After the form has been back filled to the required height, which in most cases was about 8 ft., the levers were lowered. This raised the form about 6 in., making enough side clearance so that it could be moved ahead without disturbing the tamped earth. There were three of these forms, one with each concrete gang. Some 12 to 14 men on the earth gang easily kept ahead of the concrete crew. The best progress in eight hours was 16 form lengths or 320 ft. The concrete forms (Fig. 3), which followed the earth forms were very similar in design, differing only in that the sides could be pulled toward the center before the form was raised. The equipment for each concrete gang was a ½-yd. mixer, 8 concrete buggies, one earth form and 6 concrete forms.

The alternate method of placing the sides was adopted. A runway over the forms was first used but this was afterwards abandoned as it strained the forms and the continual jar increased the tendency to float. The pouring took place on both sides at the same time. The earth bank

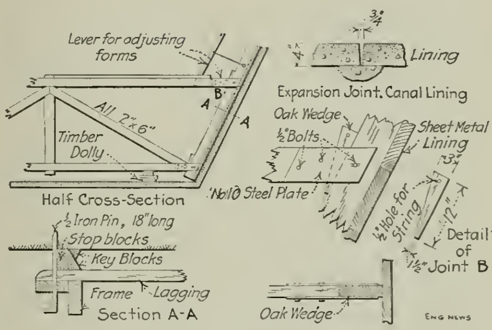

FIG. 3.

was sheltered by a piece of sheet iron and the concrete was brought up equally on each side, about 2 ft. at a time. The concrete used was a wet 1 : 3 : 5 mixture, without reinforcement. It was well tamped and spaded back of the forms.

Considerable difficulty was experienced in handling the forms at a number of bridge crossings and while all bridges were to be replaced with reinforced-concrete structures, several street crossings had to remain in a passable condition. On account of the short time in which to complete the work and furnish the spring-irrigation water, a large force of men was employed, working two shifts a greater part of the time. The limiting conditions on the work, where not hampered by bridges, sewer crossings and traffic restrictions, were the number of concrete forms per gang, as the ordinary concrete gang can handle 12 forms as well as six. One gang, where not hampered by the above obstructions, made nine 18-ft. sections in 8 hours with six 18-ft. forms.

In the settling-basin section the procedure was somewhat different. After excavation by teams, the floor was laid. The sides were then roughly trimmed, after which 2x4's were laid every 10 ft. (Fig. 6) along each side of the floor on a 1 to 1 slope. The concrete for the sides was mixed to a good pasty consistency, carried to the point of

FIG. 4. FORM FOR EARTH BACK-FILLING GOING INTO POSITION

FIG. 5. EARTH SECTION OF BACK-FILLING COMPLETED, READY FOR CONCRETE

up in wheelbarrows and placed on the concrete slope with a square pointed, short-handled shovel and lightly tamped with the back of the shovel. An important point in placing the sides is to have the shovelers throw the concrete so that it lands in a compact mass with no tendency to spread, which gives a more even and better mass. It was interesting to note the addition of water to the mix as the men gained proficiency in the work. Beginning with a dry mix, they soon could handle it fairly wet. As soon as the 10-ft. space was filled, the 2x4's were removed and the space left was filled with concrete. The concrete as placed was left with a rough surface. A thin 1:3 mortar was made to plaster this surface and applied a few minutes after the concrete had been placed. Expansion joints were placed every 50 ft. throughout this section (see detail, part of Fig. 3).

The work on this division includes the lining of three different sections. Some of the best day's work on them were as follows:

	Sq. ft.
500 lin.ft. of floor 11 ft. wide	5[illegible]
286 lin.ft. of sides 7 ft. 11 in. high	[illegible]
276 lin.ft. of sides 7 ft. 8 in. high	[illegible]
370 lin.ft. of sides 11 ft. high (settling basin)	[illegible]

The length of slope in the settling basin is 11 ft. and though this was placed with little difficulty it is about the limit in height for one course.

Instructions to begin this work were received on Dec.

FIG. 6. PLACING CONCRETE LINING WITHOUT FORMS; SETTLING BASIN OF FRANKLIN CANAL

20, 1913. Immediately material was ordered, men and teams secured and an organization assembled to handle this work in the three months available time. On Jan. 20, 1100 men and 700 animals were at work. The laborers were Mexicans receiving $1.25 per day; carpenters were, with a few exceptions, Americans and were paid $5 per day of eight hours. In general the skilled labor was selected from various construction companies in El Paso. On Mar. 23, water was diverted into the completed canal and irrigation for the El Paso Valley began. Portions of

FIG. 7. CONCRETE-LINED CANAL ON 38° CURVE, EL PASO, TEX.

the finished structure are shown by the front-page view and by Fig. 7.

Tables I and II show the total quantities and unit

TABLE I. COST OF CONCRETE LINING ON EIGHTH ST., EL PASO (STA. 78-146)

(This lining was 4 in. thick at top, 5 in. at bottom. The canal had a bottom width of 16 ft., ½ to 1 side slopes, and a depth of 7 ft. 8 in. (Fig. 1); all side work was placed with special movable forms. A 1: 3: 5 mix was used.)

Total quantities			
Cu.yd.	Lin.ft.	Sq.ft.	Total cost
2649.6	6066.7	203.835	$33,649.92

Items	Unit costs Cu.yd.	Lin.ft.	Sq.ft.
1. Engineering, superintendence and inspection	$0.491	$0.199	$0.0063
2. Form work, labor, material	2.120	0.925	0.0275
3. Concrete, materials, mixing	5.290	2.310	0.0687
4. Concrete, placing, finishing	1.650	0.720	0.0215
Total	$9.551	$4.154	$0.1240
5. Backfilling, trimming	3.150	1.370	0.0410
Total	$12.201	$5.524	$0.1650

No. 3 includes cost of material, $3.54 per cu.yd., and all expenses incident to mixers and mixing, labor and repairs. The mixers made 25 separate moves and setups on this work.

No. 5 includes all handwork necessary before placing concrete but not the rough excavation to line and grade by teams. The original canal was 28 to 36 ft. wide, and about 3.5 ft. deep. The banks wer raised 18 in. to 2 ft. and the remainder of the 8 ft. of depth was in excavation.

No general office expenses are included.

TABLE II. CONCRETE LINING STATIONS 0-38

(This includes three different water sections (see Fig. 1). No. 1, stations 0 to 6; No. 2, along river, stations 6 to 20; No. 3, along river, stations 20 to 38. All lining was 4 in. thick, laid up without forms on a 1 to 1 slope. The slope lengths on Sec. 1 were 11 ft., on Sec. 2 and 3, 7 ft. 1 in. to 7 ft. 8 in.)

Total quantities		
Cu.yd.	Sq.ft.	Total Cost
1546.8	129.324	$13,145.23

Items	Unit costs Cu.yd.	Sq.ft.
1 Engineering, superintendence, inspection	$0.491	$0.006
2 Forms, labor, materials	0.243	0.003
3 Concrete, materials, labor	5.290	0.066
4 Concrete, placing, finishing	1.062	0.013
Total	$7.086	$0.088
5 Backfilling, trimming	1.425	0.017
Total	$8.511	$0.105

For conditions relating to Nos. 3 and 5, see footnotes to Table I.

costs of this work. The night work increased the cost probably 10% and with a less rush job a material reduction in all items is possible. All work was carried on by force account under eight-hour-day law. Otis L. McIntyre was Assistant Engineer in direct charge of the work, assisted by F. W. Cater, Assistant Engineer.

Old Wood Sewers in Boston, Mass.

(CONTRIBUTED)

The sudden sinking of small sections of the surface of some of the downtown streets in Boston, Mass., caused by the collapse ot old wood sewers, has created considerable interest in them locally from time to time and has led to speculation as to the probability of serious damage being caused by such subsidence.

From an investigation by Edgar S. Dorr, of the Sewer Division, Public Works Department, it appears that in 1909 there were over ten miles of wood sewers in Boston. Many of them had been paralleled by masonry sewers or had been abandoned for some other reason, but it is estimated that even now there are in use not less than six miles of old wood sewers, which ought to be rebuilt very soon and that the cost of replacing them with permanent materials would be about $600,000.

These wood sewers were built many years ago, long before any comprehensive system of sewerage with intercepters and pumping stations was thought of, and as they were largely in low or filled lands and below the level of high tide, they were well soaked twice a day and consequently were not liable to decay as wood was cheap at that time, such sewers were economical to build. Under the conditions then existing the use of wood for sewers was good engineering.

In 1884, the growth of the city and the pressing need of discharging the sewage at more remote points led to the construction of an intercepting system from which the sea water was excluded by means of tide gates. This made a radical and unfavorable change in the condition of the wood sewers which, instead of being thoroughly wet twice daily, were wet only when they were filled by a very heavy rainfall. Long periods usually intervened between wettings and the decay of the tops of the sewers, beginning then, has been going on ever since, until now they are in such a condition that breakdowns are becoming increasingly frequent. Although they have not yet caused any serious damage, it is apparent that before long it will become necessary to replace them with modern sewers.

The Popularity of Engineering is shown in many ways. At a meeting of the Connecticut Master Plumbers' Association, a member objected to the name plumbers and said they should be called "sanitary engineers."

Field and Office

A Cable Drag Scraper on Mississippi Levee Work

The firm of R. H. & G. A. McWilliams, of Chicago and Memphis, has recently perfected and has now under operation on the Mississippi, near Memphis, Tenn., a cable drag scraper which is proving very successful in the construction of levees. The machine consists of the familiar drag-scraper bucket hung on a cable between two towers, one a braced tower of considerable height and independent rigidity, located back of the levee to be made and the other, a single low A-frame with counterweighted

Fig. 1. Looking toward levee. Fig. 2. Looking toward tall tower

A Cable Drag Scraper Building Levee at Scanlon's Landing, Mississippi River

dead-man to balance the cable, located about 500 ft. riverward. The cable is pulled by a donkey engine located at the high or shore tower. The bucket picks up the earth from the borrow pit between the towers and drags it along to the levee where it is dumped, the empty and full bucket sliding over the levee, serving to compact the fill.

The device serves admirably to fulfil the usual Mississippi levee specifications, which require that the levee be located from 1000 to 2000 ft. back from the river with earth for its construction taken from a shallow (3- to 8-ft.) borrow pit between the levee and the river.

The accompanying views show the machine in operation. Fig. 1 is a view from the low or river tower looking toward the levee under construction. The counterweight and trucks for moving the tower are clearly shown. Fig. 2 is taken looking riverward and shows the bucket just after dumping and the tracks made by the bucket in scraping up the borrow pit. In Fig. 2, the bucket is just dumping on the levee.

The McWilliams cable work now in use at Scanlon's Landing, is moving about 1800 cu.yd. per day at a saving of about 30% over the team-scraper methods usually employed. A 2½-cu.yd. bucket is used and it deposits layers of from 18 to 24 in. The round trip of the bucket averages about 2 minutes.

Excavating Railway Cuts with a Grading Machine

By J. R. Taft*

This method of taking out railway cuts is unusual, as local conditions in general do not permit the use of such an outfit except for work which may be spread over comparatively large areas at shallow depths, such as soil stripping, borrow pits, and the like.

The Halite & Northern R.R. is a standard-gage steam railway about 3½ mi. long, from Halite to near Retsof, Livingston County, N. Y. It is operated and maintained

by the Genesee & Wyoming R.R., which furnishes connections with six trunk lines. The roadbed width at subgrade is 20 ft. in cuts (14 ft. 6 in. between ditches) and 16 ft. on fills, with slopes of 1 on 1½. The subgrade is about 18 in. below top of rail, with 7 in. of ballast under the ties. Fig. 1 gives the profile of the line.

Owing to the rolling character of the country, consequent long haul, and apparent absence of rock or stone, the contractors decided to take out the cuts by grading machine and wagons. The cuts so excavated contained altogether about 20,000 cu.yd., place measurement, or 57% of the yardage of the entire line, which averaged about 11,000 yd. per mile and aggregated about 35,000 cu.yd. Of the 20,000 cu.yd. in the cuts indicated, 94% was removed by machine. The remaining 6% was

*2 Church St., New York, N. Y.

unfavorable for machine work, being either root-bound surface soil or high places at the bottom of cuts.

An Austin elevating grader, hauled by a 20-ton steam tractor, was used for the work. The wagons were of 1½-yd. capacity, of the bottom-dump type, with three mules to each wagon. The outfit was supplemented with a light grading equipment of fresno, wheel and drag scrapers, for use in places inaccessible to the grading machine.

The material encountered was a stiff clay, hard and brittle when dry, but so plastic and slippery when wet as to be unworkable. Much ditching and draining were necessary. The work of grading was started about the middle of October, 1911. Owing to the effect of unfavorable weather upon the material, the grading machine was helpless during the greater part of November, December and January. Operations were suspended during February and March, 1912, and were resumed about the middle of April.

It was demonstrated early in the grading that a 20-ft. cut is too narrow for a machine to work in and load wagons when the cut has reached a depth too great for the wagons alongside to "straddle" the top edge of the slopes. This workable depth may be taken at about 3 ft. To secure additional width, the contractors were allowed to excavate as shown in Fig. 3. When the cut had

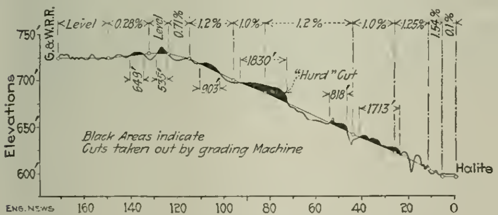

FIG. 1. PROFILE OF HALITE & NORTHERN RY.

reached a depth where the toes of the slopes were 30 ft. apart, the sides were taken down vertically to within 5 in. of subgrade.

The material shown in the hatched areas at the bottom was then cast into the double-hatched areas at the sides. In ordinary material this is not good practice. The results as a whole have proved generally satisfactory, and this method provided more room for working without enlarging the size of the cuts and thereby increasing the quantity of material to be moved.

Even a 30-ft. cut did not provide sufficient room for loading all the material direct to wagons working in the cut. There was plenty of room when excavating along either side of the cut and for about one-third the distance across the bottom from each side. In taking out the middle third, however, considerable rehandling was necessary. This meant that about one-third of the material was cast up on the sides, to be raked down by slopers into a position from which it could be again picked up by the machine. In order to do this, the machine was obliged to work casting up alone, which resulted in much "lost motion". This condition was relieved by putting the teams on light grading elsewhere while the machine worked casting up without the wagons, as shown in Fig. 2.

In material of this character, for about every 60 ft. the machine traveled, a wagon load of a little less than 1 cu.yd. place measurement, would be passed over the

FIG. 2. EXCAVATING A CUT WITH A GRADING MACHINE
(The machine is casting the dirt on the slope, to be shoveled down and loaded later.)

belt conveyor. Thus about 15 yd. were cast up for rehandling for each furrow so made through a cut 1000 ft. long. Therefore, in taking out the middle portion of the cut (six lifts of about 12 furrows each) the quantity of material turned over for a second handling runs into considerable yardage.

When the output of an organization is dependent upon a single one of its units, the results of its operation are measured by the efficiency of that unit. Therefore, to secure the most satisfactory results the unit must be worked to its economical capacity. This is not so difficult of accomplishment when operating under favorable conditions. On this work, however, such conditions did not exist. Bad water kept the boiler of the traction engine in a choked and leaky condition. Owing to this and the long water haul to reach some of the cuts, an extra tank wagon was required part of the time.

Stones embedded in the tough material when caught by the plow point threw severe strains into the whole apparatus, causing some of the most serious breakdowns. Such strains were relieved, however, by the shearing of the bolt in the plow frame which took the force of the impact. Hundreds of these bolts were broken and replaced, causing unrecorded delays of 5 to 15 min. each. The cramped area while working in certain cuts made it impossible at times to water the boiler from the tank wagons while in motion, which resulted in further delays at the turns. Owing to street paving and other activities in the cities, together with highway construction in near-by towns, it was extremely difficult to procure men and teams at a reasonable figure. Farmers were unwilling to subject their horses to the hard work of moving material of the nature encountered.

The total time of 119 days in which the machine was working in the cuts, and which does not include the removal of about 4000 cu.yd. from a borrow pit under more favorable conditions, may be classified as follows:

	Days	Per cent.
Unnecessary delays:		
Lack of duplicate parts	6	5
Delayed by work elsewhere on the line	5	4
Total	11	9
Necessary delays:		
General repairs	6	5
Wet ground	43	36
Total	49	41
Total delays	60	50
Machine in operation	59	50
Total working time	119	100

It will be evident that the work as a whole was not executed under favorable conditions. Eliminating the item of wet ground from the total working time of 119 days, 76 days were consumed in excavating about 20,000 yd., or a daily average of about 260 yd. This is less than

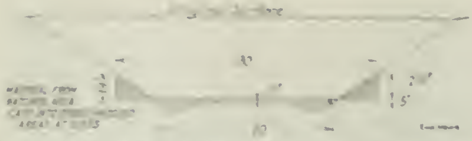

FIG. 3. EXCAVATING A 24-FT. CUT TO A TEMPORARY WIDTH OF 30-FT. TO ENABLE A GRADING MACHINE TO BE USED

half of what might be reasonably expected from a machine of this type working in similar material but in less constricted areas.

The contractor's daily expense for the operation and maintenance of this outfit may be considered as given in the accompanying table:

TABLE OF CONTRACTOR'S DAILY EXPENSE FOR GRADING

(A) At Working Point	
Foreman (member of firm)	$6.00
Tractor engineman	4.00
Tractor steersman	2.00
Machine operator	3.00
Tank-wagon driver	2.00
Extra tank wagon with driver	5.50
	$22.50
Fuel, oils, etc., for tractor	5.00
Six dump-wagon drivers at $2	12.00
Two dumpmen at $2.25	4.50
	[illegible]
Total at working point	$44.00
(B) At Camp	
One blacksmith	$3.00
One barnman at $40 per month and board	2.00
One cook at $40 per month and board	2.00
	$7.00
Corral expenses for 25 head of mule stock	20.00
Total at camp	$27.00
Total of (A) and (B)	$71.00
For insurance, interest, depreciation, etc., 12½%	9.00
Grand total	$80.00

Assuming $80 as a fair figure for daily expenses, the cost of moving 260 cu.yd. per day is about 31c. per cu. yd. Board with lodging in camp was furnished the men at $4.50 per week, which was practically at cost. Corral expense is based on oats at 61c. per bushel, loose hay at $21 per ton, and straw at $10 per ton, all haulage by contractor.

With the exception of the barnman and cook, who were carried monthly, the contractor's force was employed on an hourly basis. In the event of extensive repairs or delays from various causes, the men were either put on other work or temporarily laid off. Although changing during working hours from one type of work to another does not lead to economical results, it sometimes avoids a total loss.

The writer found it useful to maintain a chart showing grading performance, a portion of which and covering operations in the "Hurd" cut is shown in Fig. 4. For this chart, sheets of ordinary cross-section paper were used. To indicate grading-machine operation, the sheets were ruled vertically into days of 12 hr., each horizontal square representing one hour. Normal working days of 10 hr. were from 6:30 a.m. till 6 p.m. with 1½ hr. for lunch at 11:30. The number of wagon loads was recorded in the field with a punch counting machine by the engineman on the tractor. This daily record, with due consideration of voids in the material as loaded, served for a rough check on the quantity of earth moved as figured from the cross-section sheets.

This work was under the direction of W. H. Coverdale, Consulting Engineer, 66 Broadway, New York, N. Y., who acted as Chief Engineer, and for whom the writer was Superintendent of Construction.

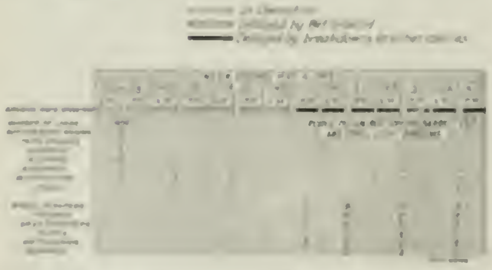

FIG. 4. TYPE OF CONTRACTOR'S WEEKLY LABOR REPORT ON RAILWAY EXCAVATION WITH AN ELEVATING GRADER

An Excavating Traction Grader

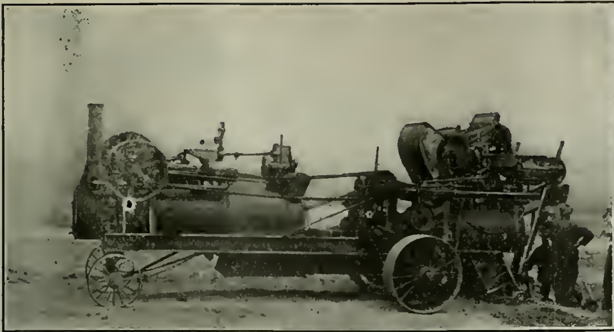
A machine specially designed and built for street-grading work, practically a heavy shallow-trench traction digger, is now in operation in Chicago. In this equipment, the excavating unit, a vertical flight of heavy digging buckets, carried on a triangular frame, is mounted on the rear of a long 4-wheeled truck. At the top, the flight of digging buckets has two points of support, carrying it almost horizontally over a transverse belt of steel slats, which distributes the excavated material to either side as required. On the truck is mounted a horizontal boiler with superimposed horizontal engine. The rated capacity of the machine is from 40 to 60 cu.yd. per hour.

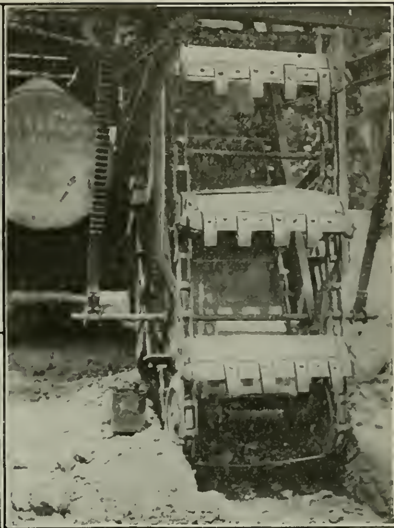
Three principal elements make up the equipment, the digging and elevating unit, the distributing unit and the truck, power equipment, traction, steering gear, etc. The digging system embraces a flight of 11 heavy buckets 33 in. wide, with an individual capacity of ½ cu.ft. This flight revolves so as to dig upward and into the earth, and along the lower side works in an elevator channel of heavy steel plate. The digging buckets travel at a speed of about 140 ft. per min. The buckets are fitted with detachable and renewable teeth and cutting edges.

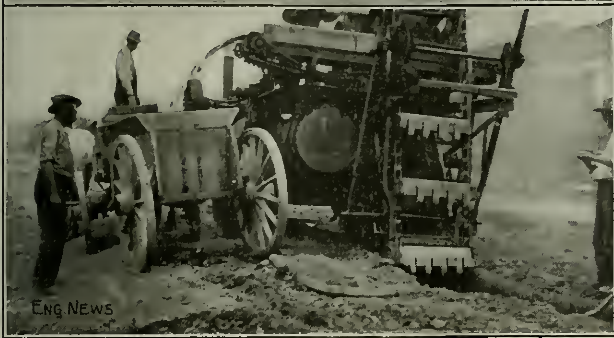
The buckets dig a trench 33 in. wide, 4 in. to 36 in. deep. The train of buckets is mounted off center, so that the outer edge of the trench is 8 in. outside of the tread of the rear traction wheel. This allows digging close up against a curb. The depth of digging is controlled by means of a rack and pinion on each side.

When digging, the grader moves forward automatically, an eccentric rod from the main countershaft and a dog and ratchet carrying a slow motion down to the rear wheels by sprocket and chains. The machine is driven forward at a speed of from 5 ft. to 20 ft. per min., depending on the material.

The transverse distributing unit, a belt built of steel cross-slats on rollers 11 ft. apart, is mounted so as to be fed by the buckets as they dump and, moving at about 300 ft. per min., dumps the material into wagons on either side. The belt is 18 in. wide, and the slats are turned







Excavating Traction Grader

The Digging Buckets

Machine Loading a Wagon

up at both ends so as to form a retaining channel. The conveyor can be run so as to load wagons at either side, as the work may require.

The bed of the truck, built of heavy steel sections, is about 18 ft. long. The rear traction drive is 48 in. in diameter with a 10-in. tread. The pilot wheels are 30 in. in diameter with the same tread.

A horizontal 25-hp. boiler is carried in the bed of the truck; superimposed upon the shell of the boiler, and rigidly bolted to it, is a 15-hp. horizontal engine, driving by chain to a transverse countershaft, located midway of the machine. The machine is driven from the countershaft by sprocket and chain.

The illustrations show this grader at work in W. 56th St., Chicago, on work under contract by C. F. Conway. The equipment was designed by J. C. Clark, and built by the H. B. Sackett Screen & Chute Co., Chicago. Mechanical details were worked out by P. A. Peterson of the Sackett company.

Tie Dating and Tie-Plates for Treated Ties: L. & N. R.R.

For marking treated ties with the date of laying, in order to keep record of their life, the Louisville & Nashville R.R. uses nails having the two last figures of the year stamped in the head. This is very general practice, but difficulty in keeping the records occurs sometimes through the head of the nail being broken or damaged so that the date mark cannot be read. To provide against this, a system has been adopted of indicating the date by the position of the nail in the tie, as shown in Fig. 1.

This road uses zinc-treated ties on tangents and creosoted ties on curves, and protects the latter against mechanical wear by means of metal tie-plates. The form of the tie-plate is shown in Fig. 2. It is of the shoulder type, and has two ribs on the underside, the depth of these ribs being sufficient to secure the plate against displacement but not sufficient to injure the wood or penetrate the more heavily treated exterior portion of the tie. The circular holes are for screws attaching the plate to the tie without relying upon the hold of the rail spikes.

For information as to the above we are indebted to W. H. Courtenay, Chief Engineer, and J. B. Lindsey, Superintendent of Treating Plants, Louisville & Nashville R.R.

Fig. 1. Side View of Hydraulic Fill Replacing a Trestle; Spokane, Portland & Seattle Ry.

A 40-ft. Railway Bank Made by Hydraulic Fill

Probably the highest railway embankment ever made by hydraulic fill is on the Spokane, Portland & Seattle Ry, along the Columbia River. It is made of fine sand pumped from the river. The elevation of track is 60 ft. above low water, and the fill has an average height of 40 ft. In Fig. 1, the partly completed bank is seen from below, while Fig. 2 is a view on top of one of the levels.

The dredge "North Bank" was designed and built for the embankment work. In Fig. 1, this dredge is just visible in the extreme left background. It has a wood hull, 148 ft. by 34 ft. There are two 250-hp. Scotch marine boilers, and a horizontal compound engine of about 600 hp. A full equipment of pumps, hammer rigging, shop machinery, etc., is provided. The dredge has both jet and mechanical agitators, and a specially designed high-lift sand pump with 18-in. suction and discharge.

The slopes of the finished embankment are $1\frac{3}{4}$ to 1. The bulkheads for retaining the material are composed of 2x4-in. stakes, 4 ft. apart, on which are nailed 1x12-in. boards. The end bulkhead, built in this manner, is 30 ft. high.

Riprap was placed on the river side of the fill; the back side covered with cliff droppings to prevent the sand from blowing away.

The hydraulic method of making the fill secured three important advantages: cheapness, no interruption of traffic, and absence of settlement and maintenance when the fill is completed.

William Gerig, vice-president and chief engineer of the Pacific & Eastern Ry., supervised the construction of the embankment and designed the dredge.

Fig. 2. Top of Partly Completed Hydraulic Fill

The Danger of Projecting Nails—The simplest and best thing to do is to educate the men who are responsible for leaving the nails in the board. Teach them the importance from a safety standpoint of pulling the nails out, or bending them over and hammering their points in, in a proper manner. It is safest, of course, to remove the nails entirely, but the next best thing is to hammer them in. But if they are bent over and hammered down, the work should be done in the right way. A nail bent so that the point remains a quarter inch or an eighth inch above the level of the board is still dangerous, because it is likely to tear the flesh or catch in the side of the shoe, and if the end of the nail stands up by as much as a quarter or half inch, there is danger of the point entering the upper or soft leather of the shoe. In bending and hammering down a nail, the pointed end should first be turned over at right angles by means of pliers or the claw of a hammer. The body of the nail then is bent over and hammered down so that the pointed end enters the board. All danger is then removed. [From "The Travelers Standard," Travelers Insurance Co., Hartford, Conn., June, 1914.]

Raising a 240-ft. Cableway Tower to 280 ft.

The Tunkhannock Viaduct, now under construction on the Scranton-Hallstead line revision of the Delaware, Lackawanna & Western R.R., at Nicholson, Penn., is the largest and highest concrete bridge in the world. It consists of ten 180-ft. full centered concrete arches with two 100-ft. approach arches and has a total length of 2375 ft., with a height of rail above the lowest point of the valley of 242 ft. (see Engineering News, Aug. 28, 1913, p. 417). The construction of the viaduct is being carried out by means of two parallel twin-span cableways, with spans of 1525 ft. and 1510 ft., respectively, on either side of a central tower.

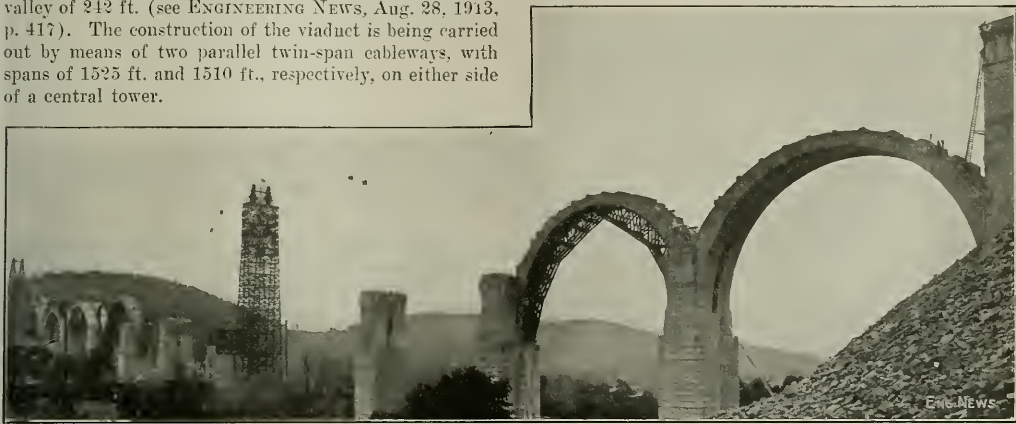

Fig. 1. The Tunkhannock Viaduct, D. L. & W. R.R., under Construction, Showing in Center the 280-Ft. Cableway Tower

The main cables are each $2\frac{1}{4}$ in. in diameter and are fitted with high-speed carriages and shock absorbing fall rope carriers. Each cable was designed for an average load of 7 tons, but is being used to carry 10-ton loads in emergencies. The end towers are independent pyramidal structures cross-braced mainly at the top lift, with each part carrying at its top the sheaves for one cableway. The middle tower, however, is a thoroughly cross-braced single tower 40x60 ft. at the base and running up to a height of 240 ft. All towers are built of timber.

At the time the cableways were erected it was decided to build the center tower high enough only to give clearance for building the main piers and arches, but not high enough to complete the superstructure. However, after the work was started the contractor decided to use the cableway for the full construction of the bridge, which necessitated the elevating of the middle tower 40 ft. from its previous height of 240 ft. to a final height of 280 ft. The elevation of the tower was completed while work on the cableway was being carried on, with a short delay for shifting the cables to the new height.

In elevating the tower two separate pyramidal timber frameworks were built on top of the tower. while the cableway was in service, and on top of each of these frameworks was placed a new balancing device similar to one which remained in service on the 240-ft. elevation, and which is described below. When this elevation was completed, the cables were slacked off so that they rested on top of the viaduct, were then unshackled and their ends raised and joined through the sheaves of the new compensating device. According to the contractor, no difficulty was experienced in putting on the additional 40 ft. or in changing the cables. The tower was apparently as rigid as it was before the 40 ft. were added. The guys bracing the lower tower were left as before, and, in addition sixteen 1-in. guy lines were added to the new upper works. In the accompanying view (Fig. 1) the raised tower is shown with the two extra frames in place. The old pyramidal frames carrying the old compensating device were left in (in second lift below top of tower. Fig. 1).

The compensating device is shown in detail in Fig. 2. It consists of a structural steel frame securely bolted to the top of the timber framework and carrying, pendulum fashion from an upper pin, two steel plates through the bottom of which are pinned plates clamped to the opposite main cableways. The control and button ropes pass over sheaves at the top of the steel frame. around sheaves mounted near the bottom of the frame and back to the end towers. The pendulum pinplate is

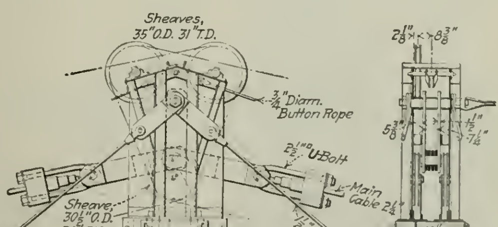

Fig. 2. Compensating Device for Long Span Twin Cableway Towers. [Patented by the Lidgerwood Mfg. Co.]

designed to permit an opposite cableway to take up the pull of an overloaded cableway on the other side and thus relieve the tower of the more severe overturning effort which would be induced by a rigid connection. Two of these balancing frames are mounted on the middle

power, one for each parallel cableway, and they are guyed to each other and to the ground.

The bridge is being built for the Delaware, Lackawanna & Western Ry., under the direction of George J. Ray, Chief Engineer, by Fuckwer & Bush, Inc. The cableway was designed and constructed by the Lidgerwood Manufacturing Co., and the patented compensating device was designed by W. J. A. Rankine of the company.

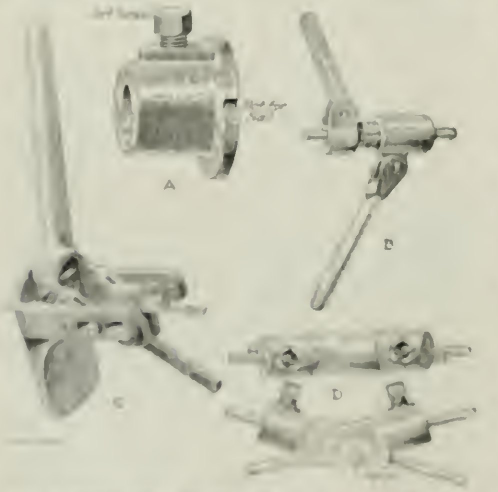
Clamp for Tie-Rods in Concrete Forms

Rod ties for concrete forms are often preferable to wire ties, and a special clamp fastening which is being introduced to hold and secure the rods is claimed to be simpler and more effective than a threaded rod with nut and washer, while it is applied in much less time. The clamp, shown at (*A*) in the accompanying cut, is a sleeve which fits over the rod, and is locked to it at any position by means of a set screw which forces the rod against a V-slot. The clamps can be nailed to the forms to prevent them from being lost. Should the form bulge or spread, a tightening wrench (*B*) is put over the end of the rod and operated as a screw jack to force the form into place.

In many cases the rods are inclosed in sleeves, but for cases where they are embedded in the concrete, a special pulling device (*C*) is used to remove the rods. This grips the projecting end of the rod and has a lever by which a powerful pull is exerted. If used before the concrete has taken a complete set, this will remove the rods without bending them and without defacing the surface of the concrete. If the rods are to be left in for any length of time, they should be jarred so as to loosen the grip of the concrete, and then they may be removed when convenient.

The clamp may be used also with outside tie rods, as in forms for columns and girders, and a special double clamp and saddle (*D*) is used to take both ends of hooped clamp rods on circular columns.

These devices have been used extensively in building construction work, and also on the retaining walls of track elevation work in Chicago. They are made by the Universal Form Clamp Co., 1214 W. Madison St., Chicago.



Clamp Fastenings for Tie-Rods in Concrete Forms

Putting a Sewer On the Map by a Subterranean Survey

By J. E. Schwaab*

The City of Alton, Ill., is contemplating the installation of a sewer system to take care of that part of the city known as North Alton. The only feasible outlet for this sewer system is the present main sewer known as the Piasa St. sewer, which consists of an arched-over creek, bearing a similar name, running through the heart of the city.

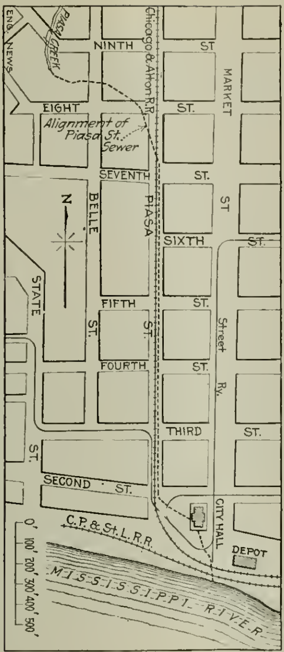
Fig. 1 Survey Party about to Start a Subterranean Sewer Survey, Alton, Ill.

This creek was arched over in 1858 but no record was made of its exact location with reference to present streets. Since then, several extensions have been made, making a total of 8078 ft., which have been arched over with arching varying from 9 to 12 ft. in span. It is now proposed to extend the arching over of this creek to North Alton for the main outlet for the proposed North Alton sewer.

This fact has given Assistant Engineer W. C. Vincent the rather unique experience of making a survey of the present Piasa St. sewer, to determine if the size, location and condition of same would warrant its being used as the outlet of the proposed sewer.

The method of procedure did not differ essentially from the ordinary transit survey, but had the additional feature of working in running water and sewage. At the outlet into the Mississippi River, the water had backed up into the sewer for a distance of 300 ft. This necessitated

*City Engineer, Alton, Ill.



SKETCH PLAN, SHOWING LOCATION OF PIASA ST. SEWER, ALTON, ILL.

the use of small boats. Hip boots proved ample in making the balance of the survey.

The task was accomplished in the following manner: (1) Transit points were established in the center of the sewer at each angle point. This was done by building up a pile of stones high enough so that the top stone protruded above the surface of the water. (2) Starting at the outlet of the sewer as 0.0, the distance along the center line was chained and pluses taken to the transit points as above described. (3) Angles and levels were obtained. This was one operation, levels being taken with the transit while securing the angles. This avoided an extra trip through the sewer.

The first set-up was made at the outlet, a sight taken on the transit point at the first angle and a backsight taken on the opposite side of the Mississippi River. The next set-up was made at the first angle point, a backsight taken at the outlet and a foresight at the next angle point. This was continued throughout the entire length of the sewer. Miner's lamps were used throughout the work, by which the rod sights were easily obtained.

The alignment and levels thus secured were rerun on the surface, as a location of the sewer was desired in respect to the city streets; and it was particularly desirous to know if it ran under the City Hall Building.

Quite a few surprises resulted as to the actual location of the old sewer. It was found that the sewer ran under the southwest corner of the City Hall at a point directly underneath a very bad settlement of the south wall of the building. This wall is now in a precarious condition.

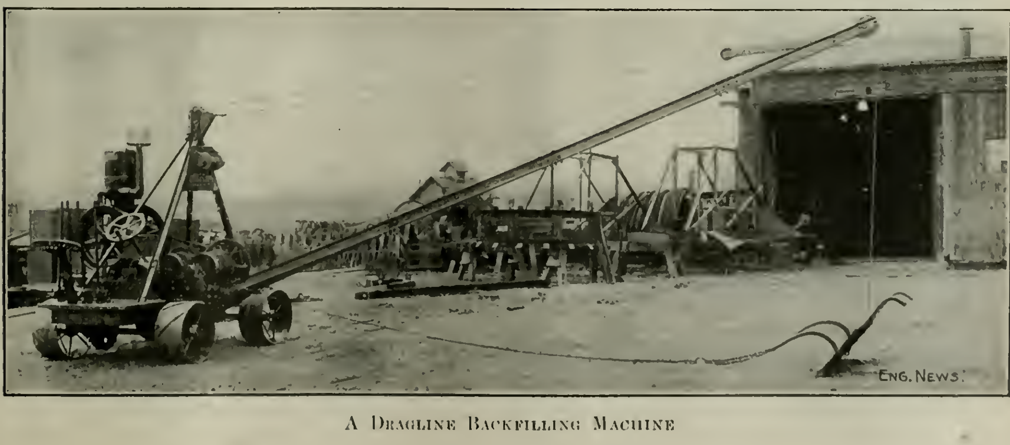
A feature not usually encountered on surveys was the vast number of bats. In several places they could be seen swarmed up on the roof of the sewer like bees. When they were disturbed by our lights they caused a commotion which was not particularly agreeable.

On a whole, the task was not as disagreeable as one might anticipate, yet it must be admitted that the fresh air and sunlight were greatly appreciated at the end of the day's work.

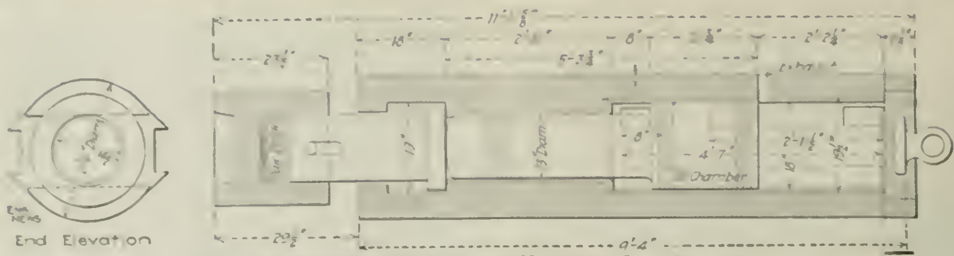
A Drag-Line Backfilling Machine

In pipe-trenching work where machines are used for excavation, the cost of backfilling (by hand) is frequently higher than that of excavation, and there is opportunity for considerable saving in this item by the use of machines instead of hand labor. The backfilling machine shown in the accompanying cut operates on the drag-line principle, the tractor traveling along the side of the ditch opposite to that on which is the spoil bank, and hauling the scraper to and fro.

The tractor has a frame 7x10½ ft., mounted on four 30-in. wheels with 18-in. tires, giving a wheelbase of 5½ ft. and a width of 5 ft. 9 in. over wheels. At one side is an A-frame, from the head of which is guyed a boom, giving a maximum reach of 22 ft. A 10-hp. gasoline engine drives a double-drum hoisting engine, and



A DRAGLINE BACKFILLING MACHINE



WILHELM DIFFERENTIAL-CYLINDER VALVELESS PILE HAMMER

also the propelling gear. The clutches of the two drums are operated by pedals, leaving the operator's hands free to work the steering wheel and the lever of the propelling-gear clutch. The boom is in four sections, put together with bolts, so that its length can be varied as required. The heel section is of V-shape, with broad base, and the head section carries the guy attachment and the sheave of the hoisting cable. The weight of the machine is 5500 to 6000 lb. Its traveling speed is 2 m.p.h.

The scraper is handled by a loading or drag line and a hoisting line. When in position behind the spoil bank (as shown), the loading line is hauled in, dragging the scraper to the edge of the trench, while the hoisting line is paid out. The latter line is then hauled in, pulling the scraper back, while the loading line is paid out. The scraper is set in position by hand, as shown, and the man may or may not keep hold of it, according to the requirements. A Fresno scraper is shown, but any kind of scraper bucket may be used.

The machine has worked at the rate of five or six strokes per minute in handling heavy clay that had been exposed for several months and had became practically a solid mass. It is designed for work with trenches up to 6 ft. wide and 20 ft. deep. It is built by the F. C. Austin Drainage Excavator Co., Railway Exchange Building, Chicago.

A Valveless Automatic Pile Hammer

A new pile hammer is just being put out which has the remarkable feature of containing no valve. The piston itself acts as its own valve, by allowing the working fluid (steam or air) to flow through by-pass ports from the ring-shaped space below the head of the piston into the main cylinder area when the top of the stroke is nearly reached. The great point of advantage of the hammer is its extreme simplicity; at the same time practical tests up to the present have indicated that it works smoothly and effectively, so that it is likely to prove an ideal contractor's tool.

Besides its extreme simplicity, an obvious feature of the hammer is the absence of any thin rod connecting the piston and the ram or striking point. This means the elimination of [illegible] breakage, and positively brings the full weight of piston and ram into action. On the other hand, the steam efficiency of this hammer is below the best steam-engine requirements. The hammer will work with air or steam.

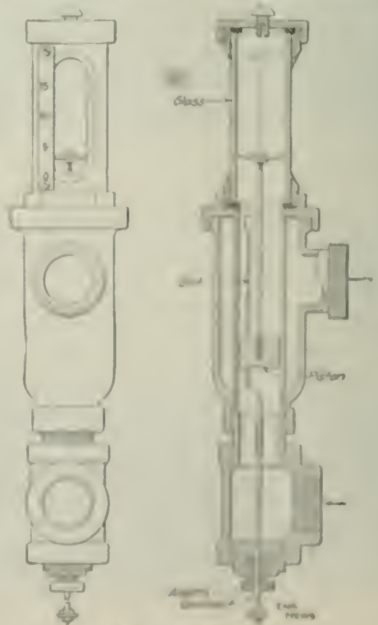
It should be noted, in addition to what the drawing shows, that two oil chambers run the full length of the main cylinder at two opposite points. These are formed in the body of the cylinder wall and are covered by the lining, but supply oil to the piston by means of a number of small oil holes through the lining. These oil chambers can be filled from the outside of the cylinder; they hold enough oil to last three or four days.

The pile cap forms an integral part of the hammer in this construction. An oak cushioning block is placed between the body of the cap and the plug or die. The latter projects into the end of the cylinder body and is held in a cross-slide in position to receive the blow of the hammer. The arrangement is fully explained by the drawing.

This new hammer was invented by J. E. Wilhelm, Cleveland, Ohio. It is being built by the Contractors Machinery Co., 2511 Elm St. N. W., Cleveland. The sizes which have been built up to the present include a 275-lb., a 500-lb. and a 1000-lb. hammer. A 5-ton hammer is now being built. The smaller hammers strike about 200 blows per minute, the large hammers probably 150 or more.

NOTES

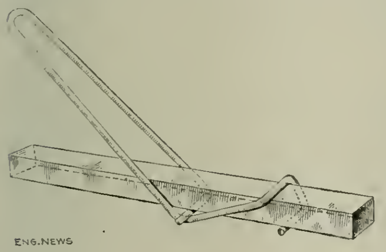
A Simple Flow Meter for indicating the flow of liquids in pipes has been designed and patented by J. F. Vaughan, of the Stone & Webster Engineering Corporation, Boston, Mass., which is applicable to a large number of piping systems, such



A SIMPLE FLOW METER

as cooling, heating, lubricating, refrigerating, boiler supply, etc. The instrument is very simple in theory and construction; it consists merely of a cylindrical chamber, with suitable pipe connections, enclosing a slotted tube with a sliding piston, on the top of which is a rod and scale indicator. When the liquid enters the lower orifice (see accompanying sketch) it enters the slotted tube through the bottom and pushes up the piston in proportion to the amount of flow, or until the orifice is large enough to allow all the flow to escape. Above the flow-measuring tube is a glass tube enclosing the piston rod with its indicator and a scale graduated to gallons per minute. An alarm system for calling attention to a stoppage or a fixed minimum of flow is provided by a brass rod set through a stuffing box at the bottom of the cylindrical chamber; on the descending piston coming in contact with the rod an electrical circuit with a lamp or bell is made. The contact rod may be adjusted to project any length into the chamber. The flow measured is proportional to the area of the slots in the cylindrical chamber, which in turn is proportional to the rise and fall of the piston. It is claimed by the makers that under test the indicator gives practically a straight line calibration over a large range, and the loss of head in operating the instrument has been found negligible, not exceeding 0.04 lb. per sq. in. with a capacity of 15 gal. per min. Screens may be used in connection with the meter, where the water or other liquid is dirty. The meter is easily cleaned by unscrewing the top and slipping out the slotted tube and glass. The Vaughan flow meter is made by W. & L. E. Gurley, Troy, N. Y., and is listed at $20 for 20-gal. capacity and $50 for 100-gal. capacity.

A New Stirrup for use in concrete reinforcement can be snapped onto the main bar very quickly and easily, and holds itself in place by a spring-friction grip. These results are secured by the peculiar bent shape of the lower end of the stirrup. The sketch explains it.



These stirrups are made (stock sizes) of ¼- and ⅜-in. round rod, in various lengths, and are intended to go on bars of ¾- to 1¼-in. size. The Diamond Expansion Bolt Co. (90 West St., New York), is the maker.

To place the stirrup on the bar, the forward hook end is slipped around the bar, and then the rear loop spread apart, dropped over the bar, and locked together again.

Breaking Up a Sunken Steel Barge—The drill barge "Teredo," a steel hull 112 ft. long, 36 ft. beam and 8 ft. deep, was sunk in the Culebra Cut on the Panama Canal by the disastrous explosion of July 20 (noted in Engineering News, July 23, 1914, p. 223). The barge was so damaged as to make impracticable its raising intact so it was broken to pieces under water and raised in sections. This breaking up was done by blowing apart the steel plates with dynamite placed in old fire hose, laid along the lines which it was intended to cut. The "Canal Record," July 29, 1914, states that by this method a clean cut was made in the plates and the sections easily lifted out.

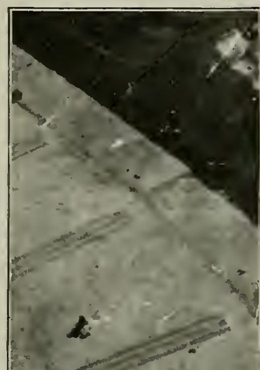
The Problem of Durable Bridge Flooring for Country Bridges—In very many cases the condition of bridges on state and county highways is not at all in keeping with the character of the highway. In the case of new construction, so far as possible, new bridges should be provided, which will be of a character corresponding to the highway improved. In cases where this is impossible existing plank floors should be replaced with some form of improved flooring, either concrete, if the structure is of sufficient strength to carry it, or creosoted blocks. This will in the end be found to be an economical measure as the increase in travel induced by the improvement to a highway subjects old bridges to an additional strain which many of them are not calculated to withstand. If such bridges were removed to some location where traffic is not so trying, and a modern bridge built at the point of improvement, both structures would last for many years.

The matter of providing satisfactory floors for those bridges which are not of sufficient strength to carry a concrete floor in addition to the live loads which they may be called on to carry, is a very serious problem. The annual cost of renewing ordinary plank floors is very great and is constantly increasing. Also it is yearly growing more and more difficult to get plank which will make a satisfactory floor. The loose, warped and twisted floors, which are getting to be so common, are a source of great annoyance to travelers and a big expense to the towns which have to maintain them. Treated wood blocks are recommended, for these may be used on many bridges whose strength will not permit the use of concrete, and when once properly laid are very nearly indestructible.

On those bridges where the cost of wood blocks is too great, a very satisfactory floor may be made by 2x4-in. scantling set on edge, spiked together one by one as they are laid, and finished with a surface coat of hot tar and sand, fine gravel or stone screenings. This makes a smooth, noiseless and durable floor and is very much cheaper than plank laid in the ordinary way. ["New York State Highway News," July, 1914.]

Orienting Oneself in the Heart of Boston—The accompanying picture is not a wall. It is a view of the sidewalk at the feet of the photographer. The sidewalk is at the corner of Hawley and Franklin St., in the city of Boston, Mass. The streets of Boston are said to follow the cowpaths of colonial days. Every uninitiated traveler in Boston believes this is true.

We don't know who is responsible for the brass marker shown in the sidewalk at the bottom of the accompanying illustration, but it is a pity the city government of Boston does not adopt the scheme generally, for even Bostonians are hazy on the points of the compass. The new Custom House tower, forming a conspicuous landmark, is said by natives to be in a different place on the horizon, when viewed from certain locations, than that which they would have naturally supposed.



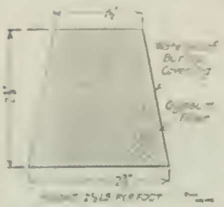
Brass Meridan in Sidewalk, Franklin and Hawley St., Boston, Mass.

The proper marking of street corners is a part of the municipal public work which is frequently overlooked. One fault to be found with Boston is that many street corners are not marked with the names of the streets, or at least there is no uniform method of posting signs. The design and erection of street sign posts, or sign and lamp posts combined, is a legitimate part of a city engineer's work, and is just as important to a well ordered city as clean streets.

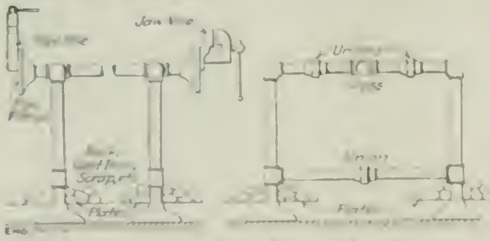
Pockets for Small Surveying Instruments — A correspondent, Frederick W. Salmon, of Birmingham, Ala., has found a convenient method of transporting various small instruments on surveying and other trips. These instruments include a watch with hand reading to ⅕ sec., for estimating distances by sound, flow of water, etc.; a passometer or pedometer, preferably the passometer; a pocket azimuth compass or pocket sextant with clinometer, for most pu-

posse the azimuth compass with a rifle to sight preferred, a pocket aneroid barometer compensated for temperature, a clinometer reading to 25 ft. and to $\frac{1}{10}$ in. on the measuring wheel, a 25-ft. steel tape in a leather box. To comfortably transport these six instruments Mr. Salmon has his pants made with six "watch pockets" below the belt line, three on each side of the center line. These pockets have flaps over them and buttons, to ensure that nothing will be lost from them in boating or riding horseback. By having the pockets made when the clothes are made there is no extra expense. The pockets are a little larger than the ordinary "watch pockets," about 3¼ to 4 in. wide at the mouth. Mr. Salmon finds that the instruments "ride better in this location than in vest and coat pockets."

A Composition Gypsum Nailing Strip or Floor Sleeper has recently been developed by the U. S. Gypsum Co., Chicago, Ill., to be used in place of the usual wooden nailing strip in concrete floors or walls. Timber embedded in concrete is very apt to decay in a short time or at least to swell when damp, and thus crack the concrete. The composition material should be free from both of these defects. The "nailing screeds" as they are called, are made in standard 6- and 8-ft. lengths of the section shown herewith. The material is a compound of gypsum and sawdust sheathed with a heavy burlap fabric. Each section is molded under pressure, and, after the filler has set, is kiln-dried, waterproofed, and cut to length. The material takes and holds nails.



A Convenient Portable Pipe-Fitting Bench which can be quickly knocked down or set up by unscrewing or screwing six unions is illustrated by the accompanying cut, sketched by a reader from a bench in actual use, but improved by him in a few details. The legs are loaded with heavy rock or this device for stream-gaging, while in the Albany office of the U. S. Geological Survey. He claims it to be especially useful in gaging streams which have wide daily fluctuations, using material as shown to make the bench firm. The dismantled bench occupies but little space. Boards can be placed lengthwise on the top of the bench, making it adaptable to many uses.



COLLAPSIBLE PIPE-FITTERS' BENCH

Efficiency Chart of Car-Loading Gang—With the accompanying chart, the efficiency of a car-loading or unloading gang can readily be estimated by the foreman, when the cost of the day's operation and the number of cubic yards handled are known. Efficiency in the following three operations can be computed: (1) unloading cinders, (2) loading rock ballast, (3) right-of-way ditching. As an example, suppose a certain day's expense was \$60 and the quantity of ditching handled 400 cu.yd. From the figure 60 on the abscissas, rise vertically to the intersection with the diagonal 400-cu.yd. line, move horizontally to the center line of unit cost, finally (still horizontally to the right) to the vertical line representing the operation performed, at which point the efficiency is indicated by the intersecting diagonal. In the case considered, the unit cost was 15c. and the efficiency 76%. The standard basis of ditching right of way is 11½c. per cu.yd.

This chart was prepared by H. A. Lloyd, Erie R.R., Jersey City, N. J., and published in the "Bulletin" of the American Hoist & Derrick Co.

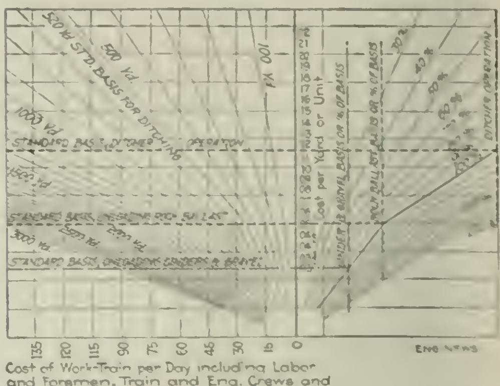


CHART COMPARING STANDARD BASIS WITH WORK-TRAIN OPERATION

Lighting a Dam at Night—The accompanying figure shows the artificial illumination provided at the new Coon Rapids Dam of the Northern Mississippi River Power Co., some six miles above Minneapolis. The structure is 2470 ft. long and has a 1000-ft. spillway surmounted by a footbridge on piers and 78 Tainter gates, 32x8 ft. A line of 100-watt tungsten lamps has been placed on goose-neck standards, one at each gate stand, to expedite foot passage and to facilitate, in dark hours, the work of handling the gates and clearing away ice and logs in some seasons. The Coon Rapids development was described in "Engineering News," July 16, 1914, and a daylight view was shown of the dam.

NIGHT LIGHTING OF DAM ON MISSISSIPPI RIVER AT COON RAPIDS

Editorials

The editorial and publication offices of Engineering News were moved on Sept. 1 to the recently completed Hill Building, at the northwest corner of 36th St. and Tenth Ave., in New York City. The building, which has been especially designed in its structure and equipment for the use of the Hill Publishing Company, is easily accessible from any part of the city by transfer to the westbound 34th St. cross-town surface cars, which pass the building. The editors of Engineering News will be glad to see any of their friends at their new home.

Five Successive Bridges on One Site

The article in this issue on the Farmville Bridge of the Norfolk & Western Ry. is of especial interest to the bridge engineer because the five successive structures which have been erected on this site since 1853 typify to a fair degree probably the changes in bridge engineering practice which have taken place within the memory of engineers still living and in active practice. The original wooden structure, at the time claimed to be, combining length and height together, the greatest bridge in the world, cost only $167,500, or about $50 per lin.ft., of which probably two-thirds was the cost of the brick piers.

It is noteworthy that this wooden structure was in service for 17 years, a longer life than any of the structures which have succeeded it.

The Fink trusses of 1870 were replaced in 1886; but curiously enough the structure of 1886 weighed less per lineal foot than the structure it replaced, though it was supposed to carry nearly twice as heavy a rolling load. Those were the days when bridge builders and designers were exercising ingenuity in saving metal. It is noteworthy that the 1886 structure required strengthening at the end of fifteen years, as did a good share of the bridges built about that time.

Direct comparison of the weight of the early bridges with the present structure cannot be made since the early bridges were trusses resting on brick piers, while the structure just completed is a steel viaduct. It is at least interesting to note, however, that while the 1886 bridge weighed only 540 lb. per lin.ft., the new steel viaduct weighs 2900 lb.

A Record Penetration for Concrete Piles

A few months ago, we called attention in these clounms to the extreme length to which it is possible to cast reinforced-concrete piles, citing then the new docks at Havana and at Halifax, at each of which piles nearly 80 ft. in length were uniformly used. In both of these structures, however, as in most places where such extreme pile lengths are used, the piles were driven in deep water, so that nearly half the pile is above ground. While this condition increases the strength requirements of the driven pile, because of the necessity of designing for the unrestrained column, at the same time the shattering action of driving the entire 80-ft. length is avoided. In the abutment piles of the Farmville High Bridge, which are described on page 522 of this issue, the condition is reversed, and the entire 60-ft. reinforced-concrete pile is driven through an old fill, which makes extremely hard driving.

So far as our records and recollection go, these piles are the longest reinforced-concrete piles ever driven for their full length through ground. Testimony of the engineer in charge that the average penetration throughout the whole length was only 3/4 in. per blow, and that the final penetration was from 1-30 to 1-40 of an inch, is sufficient evidence of the solidity of the old fill. That the piles stood up under such battering does great credit to their design and construction and incidentally is a testimonial as to the strength of the reinforced-concrete precast pile in general.

Lessons from Some Field Tests of Concrete

It must be that a number of government and private corporations engaged in concrete work are now making consistent and regular field tests on concrete, but very few of such tests have been reported. The scarcity of figures of this sort makes all the more interesting the table given by E. F. Wallace of the City Engineer's Department at Kansas City, Mo., in his article on another page in this issue on field tests of concrete for municipal work at Kansas City. At the same time the figures provoke certain thoughts regarding the application of such tests to the concrete designer's art.

We believe that the argument in favor of field tests is that it brings to the testing machine the precise material about which information is desired. A laboratory-made concrete (or even field-made concrete for laboratory purposes) must necessarily be of a higher grade than that made by the workman without any idea on his part that it is to be used for a test. In spite of this obvious fact, the lessons learned from any field test have more of an indirect effect on concrete making generally than a direct effect on the structure under test because, under present conditions, by the time the results of the tests are known, it is too late to change or remove any concrete that may fall below specification.

Suppose, for instance, at the end of 28 days, the blocks taken from a certain structure may test in compression only 650 lb. per sq.in., as with a number of the blocks in Mr. Wallace's table. By that time it is quite possible, in fact it is very probable under the usual methods of construction, that the particular concrete from which the sample was taken would be sustaining a load fully equal to the load for which it was designed under an ordinary specification unit stress of, say, 650 lb. per sq.in. What can the designer or the constructor do? By this time this concrete is buried far down in the structure or is at least so far back in the structural process as to make its

proved extremely difficult if not impossible. The sole advantage gained from the test is an indication to the engineers that either such concrete should be designed for unit stresses much lower than those used or that, in future, measures should be taken to use different methods or materials in making concrete. A byproduct of the test will be the serious concern that the designing engineer ever after has for the safety of this particular structure.

An especial instance of the fallacy of this kind of testing comes to mind in the recollection of the design of a monster concrete bridge which some years ago was widely advertised as projected in New York City. This bridge was to be designed under the assumption that the concrete in it would stand at the end of thirty days a unit stress of 3000 lb. per sq.in. in compression. At the time of this announcement, we were curious to know what the engineers would do if at the end of 30 days they found that certain concrete in the middle rib of this bridge, for instance, had stood only 2000 lb. per sq.in. Would they have torn out the whole arch-rib until they reached this particular concrete, or would they have posted notices on the finished structure stating that only two-thirds of the designed load was allowed to cross the bridge? Obviously, to make field tests of maximum utility, some very accelerated test must be devised.

A second and possibly more important feature of Mr. Wallace's test is the extremely low value that the field concrete attained. It is quite common to assume that 1 : 2 : 4 concrete at the end of 30 days is good for 2000 lb. per sq.in. in compression. On the basis of this assumption the unit compressive stress in concrete has been consistently boosted through the past ten years from 300 lb. per sq.in. to 650 and in some cases to 800 lb. per sq.in., and it is within our knowledge that certain enthusiastic supporters even claim 1000 lb. per sq.in. is not excessive. In contradiction to this, our readers will remember that W. A. Aiken, an experienced concrete tester, stated, at the recent meeting of the American Society for Testing Materials, that the crushing strength of broken stone or gravel concrete made up under ordinary field conditions will not average over 1500 lb. per sq.in. at the age of 30 days.

The Kansas City test, however, on actually made concrete shows that even this figure is high, for the 1 : 2 : 4 concretes in the table run from 403 lb. to 1657 lb., with an average of 954 lb. per sq.in. at the end of 28 days and even at the end of a half year only two out of the lot reached a higher value than 2000 lb. per sq.in. With the somewhat leaner mixtures, which were quite probably as rich as much nominal 1 : 2 : 4 concrete, the unit stresses are very much lower.

Should not such figures serve to indicate to concrete designers that the time has almost come when unit stress in concrete cannot be boosted much higher? The Kansas City concrete was practically all made for structures where great strength is not particularly necessary and undoubtedly on this account the construction and the inspection dropped below what it would have been in a high-class structure, but the remarkably low figures obtained and the perfectly obvious lack of uniformity in the strength obtained from the different takings from the same batch should at least give pause to the builder of designers and building-code makers. Field concrete is not laboratory concrete, and ordinary field concrete is not even comparable to carefully made field concrete. The adoption of a high unit stress predicates the utmost care in the supervision of the concrete making and placing.

The Business Situation and the Outlook

For a month past two subjects have absorbed the public interest almost to the exclusion of all others. The first is, of course, the gigantic struggle now in progress in Europe. The second is the effects of that conflict upon the United States. Great as is the interest felt here in the daily reports from the vast battlefields of Europe, the people of this country are most concerned with the effects of the war which they themselves experience. And the most important of these effects is not the great increase in the cost of living, due to the rise in price of all food products, heavy though the burden that brings upon all classes, from richest to poorest. More serious than this is the widespread paralysis of business, taking away employment and the means of subsistence from hundreds of thousands, and this at the very time when their small savings are most rapidly used up by the high cost of the necessaries of life.

There is probably no industry which is more severely affected by the present financial paralysis than the business carried on by engineers and contractors. Construction work on new enterprises either for corporations or cities is almost invariably carried on by borrowed money, hence cutting off the supply of funds puts an immediate stop to new work.

It is a question of greatest interest, therefore, how long before the financial machinery of the world will be again set in motion. By what means and from what source can money again be obtained to finance the important construction work now suspended all over the country?

There can be no doubt, as we pointed out in these columns a month ago, that higher rates for investment capital is one of the certainties of the future. While the war continues, those European countries which have been the chief reservoir for investment capital to supply the rest of the world, will require all the capital their people can furnish to take care of their war expenditures. When the war ends, Germany and France and England will need vast amounts of capital to make good the destruction wrought by the war and to rehabilitate their industries.

The investors of the United States, therefore, are the chief source to which borrowers must resort for a long time to come, not alone to carry on work in the United States itself, but in South America and Africa and Asia and Australia as well.

For the moment, it is true, investment business in the United States is almost at a standstill, due first to the stoppage of a large part of our important financial machinery, such as the stock exchanges, but also to the general lack of public confidence. And the last cause is as important as the first. Until the public realize that this vast war catastrophe, after all, affects only a small part of the world's inhabitants, and that the great mass of its people are going on as before, producing and selling and buying, furnishing a vast market for food, and clothing and manufactured goods—in short, until the public realizes that this great world calamity, with all its evils

and losses will also furnish great commercial opportunities to the United States, public confidence here will not be fully reëstablished.

On the other hand, when this happens—when the dam that now holds back industry is broken, a flood of phenomenal business activity may follow. It was so during our own Civil War. Vast though the destruction and disaster that then went on within our own borders, the paralysis of business at the outbreak of the war was followed by a business boom that made great profits for factories throughout the North.

The foundation conditions now exist that may bring about such a wave of business activity. The nations of Europe are eager to obtain the food products of North and South America, which are as necessary to their military operations as arms and ammunition; the price is a secondary consideration. This means hundreds of millions of dollars additional profits to the farmers of the United States and to the ranchers of Argentine. Merchants in Asia and Africa and South America are already seeking to purchase in the United States, the cloth and hardware and other merchandise which they are unable to obtain from Europe. Here again prices will be fixed on a more liberal scale than they have been under the stress of international competition. They will doubtless have to because the higher cost of living will sooner or later make necessary an increase in the wage scale.

And at no time in our history have the possibilities of raising in the United States a vast amount of capital for investment been anything like so favorable as today. A quarter century ago, an enormous amount of Eastern capital was pouring into the states from the Mississippi River to the Pacific to transform a region still virgin into farms and towns and cities. That region is now itself wealthy and is not only furnishing to a large extent the capital required for its own further development, but is buying bonds and stocks issued elsewhere.

As our own construction news columns show, engineering work in the United States is not by any means at a standstill, notwithstanding the European war. Cities are going ahead with necessary extensions of sewerage and water-supply and street-paving systems. States are proceeding with highway improvement. In general, the financing of these works just now is being taken care of directly in the locality affected. Trust companies or savings banks or the city's sinking-fund commission take the bonds, where bonds are issued, or the work is carried on by the proceeds of a tax levy or from assessments on the property benefited.

There is no doubt that the financing of such work could proceed on a much larger scale were only the financial exchanges open so that a price for investment securities might be established. At present investors are loth to purchase stocks or bonds lest they use up their available capital and find themselves unable to purchase if some more favorable opportunity is offered when business on the Exchanges is resumed.

The volume of investments could also greatly increased, it is probable, were better means adopted to reach the small investor. During the Civil War, the firm of Jay Cooke & Co. accomplished wonderful results in raising capital for the Government's necessities by popularizing the sale of Government bonds. In the Spanish-American War of 1898, the Government's offer of a 3% loan directly to the public met with an amazing response.

It must not be overlooked, either, that the ruling rate for capital has an important influence upon the amount of capital which can be obtained. Let safe bonds at six per cent. or seven per cent. be open to public subscription, and large amounts of money will be saved and invested which would be spent if the only return offered were the two per cent. of the Post Office savings banks or the four per cent. of the ordinary savings bank.

Prior to the outbreak of the war, a considerable amount of public service bonds bearing a 6% interest rate were being offered. It does not seem unreasonable to expect, therefore, that many concerns may find it now necessary to pay 7% to float bonds and doubtless an even higher rate on short-term loans.

Of course, such a high rate for capital greatly limits the field in which it can be profitably used. It also operates to materially alter the character of engineering design. The engineer to meet present conditions must solve the problem of accomplishing a desired result at the least outlay, even if he considerably increases the cost of maintenance thereby. He will probably have to cope also with high prices of labor, for the advance in the price of foods and the cost of living will inevitably tend to raise wage scales or at least prevent a reduction.

This is in fact a return to the economic conditions which existed in the '70's and early '80's, and the methods used by engineers then will have to be copied by the engineers of today. Fortunately the principal engineering materials, steel, cement, lumber, brick and stone, are not likely to have their cost increased to anything like the figure prevailing forty years or more ago. An exception might be made in the case of lumber; yet at present the stoppage of building work has made lumber more of a drug in the market than it has been for a score of years; and cargoes from the North Pacific coast through the Panama Canal to Atlantic coast markets are likely to keep down lumber prices to a moderate level for many years to come.

There will, therefore, be no need to go so far in economizing material in designing as the engineer of forty years ago went; and the development of labor-saving machinery since that time should enable the engineer nowadays to do far better work at a low labor cost than was possible then.

As to the question when it will be safe to again set in motion the financial machinery of the country, it would be difficult to prophesy. It is evident, however, that the first essential is the restoration of public confidence. With that accomplished, bankers and investors will release funds, which they are now carefully guarding for that the first essential is the restoration of public confiuse in possible emergencies.

Buying and selling of securities are in fact being carried on to a greater or less extent by private arrangement in the manner customary before exchanges were established, but of course, at far greater cost and trouble to both buyer and seller. It may safely be asserted, however, that the stock and other exchanges will be reopened just as soon as restoration of business confidence has proceeded to such an extent as to make reopening safe. Those who are responsible for the operation of these exchanges are themselves suffering such heavy financial loss through the closure of the exchanges that they are certain not to postpone reopening a single day beyond the period absolutely necessary.

Letters to the Editor

On the Necessity of Heavier Pavement Foundations

Sir—"The proof of the pudding is in the eating." On this basis, I beg to radically differ from your correspondent who on page 367 of your issue of Aug. 13, makes these statements:

(1) Four- and five-inch foundations are entirely inadequate.
(2) Municipal engineers are extremely shortsighted in continuing to recommend 6 in. as the maximum thickness.
(3) Eight inches on residence streets and 10 and 12 in. on business streets should be required.

Your correspondent's position seems to be based on:

(a) Observation of poor concrete, particularly that made of natural cement, which is no criterion for requirements of sound portland cement concrete.

(b) A statement that we must build for the future and that, as traffic increases, heavier foundations will be required than may be sufficient at the present time. In this he seems to overlook the immense crushing strength of a slab of good sound portland cement concrete having a depth of 4 in. That crushing strength is very much greater than the weight of any load which is likely to ever pass over any road surface, even though the stress on the concrete were not, as it is, very greatly relieved by the wearing surface, say 2 to 6 in. deep, depending on the character of the wearing surface.

In a paper before the American Society of Municipal Improvements at its 1909 Convention at Little Rock, on the subject of "Paving Practice with Respect to Crowns of Roadway Pavements and Concrete Foundations," the writer made the statement that, "under ordinary conditions of well rolled subsoil, 4 in. of first-class portland cement concrete is as good for a pavement foundation as 1 ft., provided the concrete is not disturbed after it is put in place until thoroughly set," and he referred to a then two-year experience as follows:

In the year 1907 the company with which the writer is connected had a contract for laying "Bitulithic" pavement on several streets, aggregating about 36,000 sq.yd. The specifications provided for foundations of rolled broken stone, grouted with bitumen.

On grading the street, a very weak clay subsoil and many recently filled trenches [illegible], on account of which the city officials permitted a change to 4 in. of portland cement concrete. Before the surface was laid on the concrete, [illegible] to be otherwise disturbed. It had become thoroughly set, and such that the wagons drawn by horses could travel through it. The 17-ton 3-wheel road roller used in consolidating the bituminous surface made no depression in the foundation.

Two years later the writer examined the streets and found them all in perfect condition, with the exception that some points over some trenches had settled. As a whole, would 8 in. of concrete have been practically any better than the 4 in. used?

But some engineers will say 4 in. of concrete is not sufficient over newly filled trenches, to which the answer is, neither is 6 in. nor 8 in., and the remedy for such cases is properly backfill trenches and as an additional precaution, provide an extra 6 in. or even a foot of concrete over and extending a few inches beyond the trench. In other words, put extra concrete where it is needed, i.e., over the trench, and don't use several times as much extra concrete over the entire street, on probably nine-tenths of which it is not required.

Based on a wide experience during the intervening five years, he has seen nothing to shake the correctness of his opinion expressed in that paper. The writer goes so far as to say, without fear of contradictory proof, that if a 4-in. portland cement concrete base has failed anywhere, it is due to one of the following causes, none of which are such as to make the general adoption of that depth of concrete undesirable.

(1) An unusually insecure subsoil which is seldom met and which should have been specifically considered by the engineer while making his plans and specifications or while the work was in progress.

(2) Poorly backfilled trenches which should have been guarded against, as they developed in rolling the subgrade, not by placing an inch or two of extra concrete over the whole street where it is not needed, but by perhaps an additional 6 to 12 in. over the weak trenches and extending 6 in. outside the trench on either side. This treatment not only provides a slab of concrete 10 to 16 in. deep, resting on solid earth on either side of the trench, which would probably successfully bridge over the trench and overcome any subsequent settlement, but would generally accomplish that essential end by the use of much less extra concrete than an extra inch or two over the whole street, which would not accomplish the desired end.

(3) Weak street railroad construction, the vibration of which naturally tends to shatter the pavement for a considerable width beyond the ends of the ties. For use with modern heavy interurban and other cars, the concrete from end to end of ties should extend from 6 in. below the bottom of ties to the bottom of the wearing surface, providing, say 18 in. of solid concrete in the railroad area. Then if a heavy rail and closely spaced heavy ties are used, there will be practically no vibration of the track and no damage to the surrounding pavement. If, however, the width between tracks and curb is less than say 16 ft., it is a wise precaution to provide 6 in. concrete for the pavement foundation outside of the railroad area.

(4) Poor concrete, perhaps the most fruitful cause of which is the laying of the pavement surface before the concrete is *thoroughly set*. Under ordinary conditions, I would rather guarantee a pavement surface laid on 4 in. of well set concrete than on 6 or even 8 in. of concrete as green as that which the public, and often engineers who should know better, demand, or the contractors want to cover, so as to get the street "finished."

While urging greater intelligent economy than is perhaps generally practiced in the laying of concrete pavement foundations, the writer deprecates the quite general, and he believes unwise, tendency toward laying thinner wearing surfaces in order to reduce the first cost. The only office of the foundation is to prevent either settlement, vibration or shattering of the foundation by the stress of vehicles passing over the pavement surface. It

has been proved that under ordinary circumstances, that result can be accomplished by either a 4-in. continuous slab of good sound portland cement concrete or by a sound macadam foundation. It is also well known that good portland cement concrete sets harder and harder with age, and I believe the increased stress of increased traffic is nearly nil.

The wearing surface, on the other hand, takes the wear, and, whatever the character of surface, more or less abrasion exists; and it rapidly increases with increased volume of traffic. When any given pavement surface is worn to less than a certain depth the surface is then too thin to sustain the weight and other conditions of traffic.

The difference in labor cost and general expense items connected with the laying of any wearing surface to a depth say one inch more or less than any given standard, is very slight, so that practically the only difference in cost is that of the surface materials.

Against this is what may be termed the "factor of wear" in connection with a greater or less depth of wearing surface. Suppose for instance, that any given wearing surface will not sustain the weight of traffic after its depth is reduced to say 1 in., then if the surface as originally laid has a depth of 2 in., the "factor of wear" is 1 in. If, however, the same character of surface is originally laid to a depth of say 1½ in., then the "factor of wear" is reduced to ½ in.—a decrease in durability of 50% in order to effect a saving in first cost of possibly 20%.

In the case of monolithic bituminous surfaces another point should be considered; to wit, that if the depth of wearing surface as laid is materially more than 2 in. after compression, there is grave danger of not getting perfect compression and the danger from that point outweighs the advantage of increased depth.

In conclusion, in the writer's judgment, true economy demands:

(1) Provide a solid foundation, but not to an unnecessary depth.

(2) Don't "skimp" in depth or in the quality of wearing surface in order to reduce the first cost. This in the end will prove to be poor economy even though the first cost is reduced.

GEO. C. WARREN.

50 Temple Place, Boston, Mass.

Boat-Design Difficulties on the New York State Barge Canal

Sir: In your issue of Aug. 27, 1914, p. 469, under the caption "Type of Boats for the New York State Barge Canal," you reprint an official statement on this subject emanating from State Engineer and Surveyor John A. Bensel. No one will question Mr. Bensel's authority on all subjects dealing with the design and construction of the canal, but when he trenches on the province of the naval architect, he shows himself rather "at sea," as one might expect. I particularly object to his statement:

> The shipbuilders have found it impracticable to design a steamer that will satisfy the requirements of the Federal Government for steam craft navigating the Great Lakes and also to keep within the limitations imposed by the Barge Canal, such as restricted clearance of 15½ ft. under bridges and other fixed structures, at high navigable stage, the narrow width of 75 ft. in land sections and shallow depth of 12 ft.

At this stage the shipbuilder and naval architect will want to ask why, if it appeared desirable to the Canal Board that the vessels trading through the canal should also traverse the Great Lakes, were these vexatious limitations Mr. Bensel refers to allowed to be imposed in the construction of the canal.

It is surely self-evident that the New York State Barge Canal must compete with the St. Lawrence system of canals which connect the Great Lakes with the head of ocean navigation at Montreal and must always be handicapped by the fact that the St. Lawrence route does permit of the passage of a combined lake and canal freighter.

The St. Lawrence Canal Locks, in fact, permit vessels of 250-ft. length by 43-ft. beam by 14-ft. draft to pass through, a size of vessel that can go anywhere on any sea in the world and though, owing to rather special construction and peculiar conditions in Canadian navigation, these vessels do not, as a rule, leave Canadian waters, they do trade on the Atlantic coast and go to Europe occasionally and have no difficulty in going anywhere. Now the really extraordinary thing is that if the new Barge Canal locks are only 14 ft. deep, they could take much larger vessels than the Canadian locks, say 300-ft. length by 44-ft. beam easily, which, at the 14-ft. draft of Canadian Canal, would carry over 3000 tons dead weight and could steam all over the Great Lakes and, in fact, all over the globe. In spite of this, by some extraordinary oversight, the bridges on the New York State Barge Canal give a clearance of only 15½ ft., a perfectly absurd dimension for any suitable type of craft with sea-going features, and the earth sections with a bottom width of 75 ft. are equally unsuitable for this ideal ship for which the canal ought to have been designed.

It is quite evident from his other remarks on the best types for use in the New York State Barge Canal that Mr. Bensel does not realize what happens when you attempt to canal a vessel 250 ft. by 40 ft. beam through a section of 75-ft. width with curves the same width as the tangents. A little experience in this line will show that in the least cross wind the vessel, possibly running light, will never be off one bank or the other, that two boats will inevitably collide when attempting to pass, and that to tie one or other of them up to allow the other to pass is to reduce the capacity of the canal to a very serious extent.

It has always seemed extraordinary to naval architects and shipbuilders who have looked into this thing that not the slightest attempt seems to have been made in designing the canal, to decide beforehand what types of boats would be the most suitable and the most likely to be built for use thereon.

Mr. Bensel refers to a solution of this problem by using strings of large steel barges, small tugs being used in the canal and large tugs out on the Great Lakes. It would be interesting to have Mr. Bensel state in what way barges for Great Lake work do not suffer from the restrictions which he states preclude the possibility of shipbuilders producing a combination steamer for canal and Lake work.

The fact is that long experience with the design and operation of Canadian vessels for use in the St. Lawrence Canal and Great Lakes trade have convinced Canadian owners that the tow barge in any form is a failure when competing with the full-sized, full-powered cargo boat

FIGS. 1 AND 2. SHELTER SHEDS ON QUEENSLAND RAILWAYS, AUSTRALIA, OF UNIT SYSTEM REINFORCED CONCRETE

that can take care of herself under all circumstances. This refers to vessels for the handling of the great staple cargoes of grain, coal, pulpwood, package freight and similar cargoes which will constitute the principal traffic for the New York State Canal. In my opinion the only solution now left to the naval architect under the extraordinary conditions imposed upon him is to devise a steel hull with fair shipshape form, large rudder, and biggest possible engine and propeller which will travel absolutely independently, be able to negotiate all bends without touching the banks or tying up, and be seaworthy enough to go round from port to port on Lakes Erie and Ontario without running the risk of disaster. It can be done, but the dimensions will be very far short of anything which Mr. Bonner has indicated, and very inferior in size and capacity to the competing Canadian canal types, and for that most unfortunate handicap the users of the New York State Barge Canal will have to hold the naval architect and the shipbuilder free from blame.

JOHN REID.

17 Battery Pl., New York City, Aug. 28, 1914.

Reinforced-Concrete Shelter Sheds on an Australian Railway

Sir—I was much interested in reading the article on p. 737, of the issue of Apr. 2, 1914, of ENGINEERING NEWS, describing the adoption of reinforced concrete for construction of shelter sheds. A similar method of construction was adopted by the Railway Department of Queensland, Australia, four or five years ago, and I give herewith views of our buildings, thinking they may be of interest.

Upon the report being made by the Engineer for Construction of the great expenditure involved in the maintenance branch of the railway for the upkeep of the wooden structures used for shelter-shed accommodation, and with a desire for a more economical method of construction, it was decided to erect in place of the wooden buildings, reinforced-concrete structures.

Upon such a decision being made, designs were prepared on the unit system with a view to facilitating erection and carrying out extensions in the quickest manner with a minimum of labor.

A general description of the method adopted, together with the accompanying view, will readily convey to the professional mind the general principles thereof.

Piers or dwarf walls are erected under the building for the reception of the superstructure, according to the requirements of the site. Beams reinforced with ½-in. rods are then placed in position. These piers are holed to receive the reinforced verticals of the side and end wall. The verticals are rebated on each side for the reception of 4-ft. by 2x18-in. wall slabs, rough cast on the outside, reinforced with netting, the reinforcing rod at the top of the vertical being extended to such length as required to receive the wooden plate placed for the reception of the rafters of the roof, and the rods at the

bottom of the vertical being bedded in the floor beams.

The floor is of concrete 4 in. thick, reinforced with rods as required, and made in 4-ft. squares. The roof is constructed of wood and covered with tile, giving the building a neat and serviceable appearance.

The cost does not exceed that of a wooden structure of corresponding size.

The unit adopted is 4 ft. for all work, that length being a measure common to all designs in our country stations. By this means additions to or deductions from can be easily effected.

R. E. SEXTON,
Engineer in Charge of Construction, Queensland Railways.

Brisbane, Queensland. June 8. 1914.

NOTES AND QUERIES

In "Engineering News," July 9, 1914, p. 72, it was stated that the puddle core wall of the Throttle dam in Raton, N. M., was faced with No. 12 gage corrugated galvanized "Ingot Iron." We have since learned that what was used was No. 20 gage corrugated painted "Ingot Iron."

Locomotive Cab Signals and Audible Track Signals in Europe

Cab signals (audible or visual) on locomotives, as auxiliary to fixed signals beside the track, have been tried only to a limited extent in this country, but have been applied extensively in Europe for the past 40 or 50 years. At the meeting of the Institution of Mechanical Engineers, of Great Britain, at Paris, in July, papers were read describing the use of cab signals on five French railways. In all cases the contact is made by a wire brush on the engine on a contact bar placed between and parallel with the rail. From the papers noted above we have compiled the following particulars as to practice on French railways.

NORTHERN RAILWAY—This road has used such signals for some 40 years. With the present equipment the contact bar or track device is set either opposite the signal or at a distance which may be as much as 650 ft. It is an oak beam 4 in. thick, 6 in. wide, and 6½ ft. long, the wood being boiled in oil for insulating and preservative purposes. It is supported on iron blocks, with its top 9½ in. above the ties and about 4 in. above the rails. The entering end is beveled off, and is protected against hanging parts on the trains by a timber 5 ft. long placed in advance of it and having its top inclined. Where trains pass at speeds of over 30 m.p.h. a second contact bar is placed against the end of the first one to insure sufficient duration of contact. The wooden bar is faced with a brass plate (on wood or porcelain washers), having riveted to the underside a square copper block which is connected to the battery wire.

The contact brush on the engine consists of a series of hard but elastic copper wires soldered to a metal plate. From this a cable leads to the electro-magnet operating the cab whistle, while the other wire from the electro-magnet is grounded through the wheels and rails. The warning apparatus has a whistle with a lever which carries a plunger valve, working in a tube connecting the whistle with the boiler or a compressed-air chamber. The lever is pulled down by a rod having a heavy spring which tends to hold the valve open, but this rod is held up normally by its lower end resting on the arm of an electro-magnet. When a current is sent through the coils of this, the magnet ceases to attract the armature, so that the arm drops and the lever is pulled down by the spring, opening the valve and causing the whistle to sound until the engineman restores the apparatus to normal position by pressing a lever.

The signal is a disk on a tall rod, which revolves on its vertical axis, and the disk has a switch operated by a finger keyed to the post which supports the rod. When the disk has revolved 70° from the "clear" position the switch makes the circuit with the track contact mechanism. The same switch operates a bell at the station to indicate the position of the signal. For the track contact there is a 12-cell battery, with its positive pole connected to the brass contact plate and its negative connected to the switch. For the station bell there is an eight-cell battery, both batteries being placed in a small concrete chamber at the foot of the signal post.

In connection with the device described there is an indicator giving visual and audible warning at the station and signal cabin when a train passes the distant signal. This has two track contacts, the first sounding the cab whistle and the second sounding a bell at the station or signal cabin; this operates for every train (or engine), regardless of the position of the signal. The apparatus in the signal cabin is a vibrating bell and a miniature blade or disk.

EASTERN RAILWAY—The system is in general similar to that of the Northern Ry., but two track contacts are used, one near the signal and the other at a distance which may be as great as 1300 ft., so that if the signal is at "stop" the engineman has an advance warning and then a second warning at the signal. The wood bar, however, has been replaced on this road by a "gridiron" of steel bars or angles, in order to eliminate contact failures due to frost.

Controlling apparatus (for which various devices have been tried) is used to prevent the engineman from shutting off the sound too quickly. In addition to this, the operation of the cab signal is recorded automatically on the continuous chart of the speed recorder, with which French locomotives are commonly equipped. The apparatus sounds a bell when the engine passes a "clear" signal, thus giving the engineman a positive indication for either position of the signal.

SOUTHERN RAILWAY—The track contact apparatus is about 12 ft. long, and the battery is on the engine instead of on the ground. A steam whistle is used, and there is both warning and recording apparatus. When an engineman sees a "stop" signal, he shifts the handle of the control apparatus and thus causes a mark to be made on the speed-indicator chart, the mark showing whether or not he has operated the device in proper time. On reading the signal, the brush on the engine makes contact with the track device, and the circuit is closed, the current operating the valve of the whistle device and two special pens in the speed indicator. The engineman can shut off the whistle device by closing the valve. This road has 20 locomotives and 30 automatic signals equipped in this way.

STATE RAILWAYS—Four cab-signal devices are being tried on this system: The Cousin (55 engines), the Van Braan (28), the Eastern Ry. (27), and the Augereau (2 engines).

PARIS, LYONS & MEDITERRANEAN RY.—This road is making experiments with 140 engines on 258 miles of line having 316 disk signals. Electricity is used only to close the circuit, all operations being done mechanically. There is an automatic device for releasing the horn and discharging compressed air through it, and another device for marking the speed-indicator chart. On engines having air brakes, the air is taken from the brake receiver; otherwise a charged receiver is placed on the engine.

PARIS & ORLEANS RY.—For over 50 years this road has employed apparatus for placing torpedoes and giving an audible signal besides the track instead of in the cab. The torpedoes are placed when the signal is set at the "stop" position, and severe punishment is prescribed for men who pass a "stop" signal. The signal is set at such a distance from the point to be protected as to enable a train to be stopped before reaching it, even if the engineman does not shut off steam and apply the brakes until he hears the torpedoes. The sound is loud enough to be heard by the trainmen and passengers. The system is considered by Mr. Solacroup (Superintendent of Motive Power) to be preferable to a cab signal, and the value of its moral effect is seen in the fact that there is no record of any accident having occurred due to a train running past a "stop" signal.

A Machine Plowing Record is reported from Fremont, Neb., where a gasoline engine "caterpillar" traction engine pulled a gang of 24 plows and turned 28 ft. wide, 7 to 8 in. deep, at 2⅛ miles per hour, equivalent to about 7¼ acres per hour. The tractor was a Holt type, with six 7¼x8-in. cylinders, developing 130 b.hp.; the caterpillar track consisted of an endless chain of treads on each side, 2 ft. wide and 10 ft. in circumference. The plow was made up of four six-base Oliver units handled with one hitch.

Putting a Concrete Lining, Later a New Skin, on an Old Hull

By Horace M. [illegible]*

The general deterioration of the steel hull of a steam launch after 14 years' service, demanded unusual methods to save the boat. The first protective measure was to line the hull with cinder concrete reinforced with chicken wire. This served for several years when the shell was so thin that it was feared the concrete would drop out. A new steel skin was then put on.

The hull was 65½ ft. long, 10½-ft. beam, and was 4 ft. deep amidships; the plating was of soft steel, 11¼ lb. per sq.ft. The draft was 20 to 24 in., according to load, and the wheel 36 in. in diameter. The wheel revolves in a tunnel, and when the boat is not under way only about two-thirds is below the water line; but it is submerged while running, the water rises and fills the tunnel.

The boat was originally driven by a triple-expansion direct-connected steam engine, which developed 90 to 100 hp. at 300 r.p.m., and attained a speed of 13.6 mi. per hr. in still water. Later a quadruple-expansion condensing engine was installed, which, though it developed 135 hp., increased the speed only to about 15 mi. per hr. At [illegible] hp., the speed was 17½ mi. per hr.

The boat was built in 1887 at a cost of $10,000 and purchased by the United States government in 1902 for half that amount, for purposes of inspection and light towing on shallow rivers.

Fuel consumption was small (about 180 lb. of coal per hr.), costing 40 cents. Storage capacity, however, was only about three tons, which limited travel between coal piles to about 30 hours. The crew comprised a pilot, engineer and fireman.

In 1909, the engine and boiler were removed and a 50-hp. four-cylinder, four-cycle gasoline engine installed. The gasoline consumption is 6 gal. per hour. The storage capacity is 120 gal. A new pilot house was constructed suspended half in the engine room and half extending above the roof, so as to give pilot-house control and enable one man to run the boat.

When the boat was 11 years old, "pinholes" developed all over the plating and the plates were so rusted that it became an every-day occurrence to knock a hole in the bottom during low water and sink the boat.

This state of affairs was met by a concrete lining. The hull, inside, was thoroughly scraped and cleaned. Chicken wire was spread over the ribs, and cinder concrete was tamped down through the mesh all over the bottom of the boat, extending well up on the sides above the waterline. The lining was from 4 to 5 in. thick at the keel and thinned toward the sides of the hull. The added weight was 8000 lb., which increased the draught 4 to 6

*[illegible]

in. The boat now worked satisfactorily for three or four years when the steel plates had grown so thin that it was feared the concrete would drop out through the bottom. In other respects, the boat was in good condition.

In dry dock, templates were made to fit the bottom, at intervals of 2 ft. From these a timber frame was built with ribs of 2x4-in. pine. Metal plates of No. 10 gage were bolted transversely on the outside of this frame, with seams lapped and riveted, with thin tar paper between the lap of the metal plates. The timber frame was then removed.

The dry dock was flooded, the boat floated over the shell, and the dock was raised. Guide posts placed the boat accurately above the shell as the dock came up. Melted paving pitch was poured in the space between the hull and the new skin. A 2x4-in. wood nosing strip running around the top of the new construction was bolted on through the shell and hull. About 7000 lb. of concrete were taken out of the hull, leaving only the concrete which was under the engine bed. After the work was finished, the draft was 18 in. forward and 27 in. aft.

The shell cost $419, and the labor of constructing it about the same amount. It is expected that the new skin will last 12 or 15 years. A new hull would have cost from $3000 to $4000.

The accompanying photographs show the boat at several stages of the work.

The Transportation of Debris by Running Water*

By Grove Karl Gilbert

Scope—The finer débris transported by a stream is borne in suspension. The coarser is swept along the channel bed. The suspended load is readily sampled and estimated, and much is known as to its quantity. The bed load is inaccessible and we are without definite information as to its amount. The primary purpose of the investigation was to learn the laws which control the movement of bed load, and especially to determine how the quantity of load is related to the stream's slope and discharge and to the degree of comminution of the débris.

Method.—To this end a laboratory was equipped at Berkeley, Calif., and experiments were performed in which each of the three conditions mentioned was separately varied and the resulting variations of load were observed and measured. Sand and gravel were sorted by sieves into grades of uniform size. Determinate discharges were used. In each experiment a specific load was fed to a stream of specific width and discharge, and measurement was made of the slope to which the stream automatically adjusted its bed so as to enable the current to transport the load.

The Slope Factor—For each combination of discharge, width, and grade of débris there is a slope, called competent slope, which limits transportation. With lower slopes there is no load, or the stream has no capacity† for load. With higher slopes capacity exists; and increase of slope gives increase of capacity. The value of capacity is approximately proportional to a power of the excess of slope above constant slope. If S equal the stream's slope and σ equal competent slope, then the stream's capacity varies as $(S - \sigma)^n$. This is not a deductive, but an empiric law. The exponent n has not a fixed value, but an indefinite series of values depending on conditions. Its range of values in the experience of the laboratory is from 0.93 to 2.37, the values being greater as the discharges are smaller or the débris is coarser.

The Discharge Factor—For each combination of width, slope and grade of débris there is a competent discharge k. Calling the stream's discharge Q, the stream's capacity varies as $(Q - k)^o$. The observed range of values for o is from 0.81 to 1.24, the values being greater as the slopes are smaller or the débris is coarser. Under like conditions o is less than n; or, in other words, capacity is less sensitive to changes of discharge than to changes of slope.

The Fineness Factor—For each combination of width, slope and discharge, there is a limiting fineness of débris below which no transportation takes place. Calling fineness (or degree of comminution) F and competent fineness ϕ, the stream's capacity varies $(F - \phi)_p$. The observed range of values for p is from 0.50 to 0.62, the values being greater as slopes and discharges are smaller. Capacity is less sensitive to changes in fineness of débris than to changes in discharge or slope.

The Form Factor—Most of the experiments were with straight channels. A few with crooked channels yielded nearly the same estimates of capacity. The ratio of depth to width is a more important factor. For any combination of slope, discharge and fineness, it is possible to reduce capacity to zero by making the stream very wide and shallow or very narrow and deep. Between these extremes is a particular ratio of depth to width ρ, corresponding to a maximum capacity. The values of ρ range, under laboratory conditions, from 0.5 to 0.04, being greater as slope, discharge and fineness are less.

Velocity—The velocity which determines capacity for bed load is that near the stream's bed, but attempts to measure bed velocity were not successful. Mean velocity was measured instead. To make a definite comparison between capacity and mean velocity it is necessary to postulate constancy in some accessory condition. If slope be the constant, in which case velocity changes with discharge, capacity varies on the average with the 3.2 power of velocity. If discharge be the constant, in which case velocity changes with slope, capacity varies on the average with the fourth power of velocity. If depth be the constant, in which case velocity changes with simultaneous changes of slope and discharge, capacity varies on the average with the 3.7 power of velocity. The power expressing the sensitiveness of capacity to changes of mean velocity has in each case a wide range of values, being greater as slope, discharge and fineness are less.

Mixtures—In general, débris composed of particles of a single size is moved less freely than débris containing particles of many sizes. If fine material be added to coarse, not only is the total load increased but a greater quantity of the coarse material is carried.

Modes of Transportation; Movement of Particles—Some particles of the bed load slide; many roll; the multitude make short skips or leaps, the process being

*Author's prefatory abstract of Professional Paper 86, U. S. Geological Survey, Washington, D. C. The paper itself is "based on an experiment made with the assistance of Edward C. Murphy," at the University of California.

†Capacity is defined for the purposes of this paper as the maximum load of a given kind of débris which a given stream can transport.

[illegible] suspension. When particles of many sizes are moved together the larger ones are [illegible].

MODES OF TRANSPORTATION, COLLECTIVE MOVEMENT—When the conditions are such that the bed load is small, the bed is molded into hills, called dunes, which travel downstream. Their mode of advance is like that of eolian dunes, the current eroding their upstream faces and depositing the eroded material on the downstream faces. With any progressive change of conditions tending to increase the load, the dunes eventually disappear and the débris surface becomes smooth. The smooth phase is in turn succeeded by a second rhythmic phase, in which a system of hills travel upstream. These are called antidunes, and their movement is accomplished by erosion on the downstream face and deposition on the upstream face. Both rhythms of débris movement are initiated by rhythms of water movement.

APPLICATION OF FORMULAS—While the principles discovered in the laboratory are necessarily involved in the work of rivers, the laboratory formulas are not immediately available for the discussion of river problems. Being both empiric and complex, they will not bear extensive extrapolation. Under some circumstances they may be used to compare the work of one stream with that of another stream of the same type, but they do not permit an estimate of a river's capacity to be based on the determined capacities of laboratory streams. The investigation made an advance in the direction of its primary goal, but the goal was not reached.

LOAD VERSUS ENERGY—The energy of a stream is measured by the product of its discharge (mass per unit time), its slope, and the acceleration of gravity. In a stream without load the energy is expended in flow resistances, which are greater as velocity and viscosity are greater. Load, including that carried in suspension and that dragged along the bed, affects the energy in three ways: (1) It adds its mass to the mass of the water and increases the stock of energy *pro rata*. (2) Its transportation involves mechanical work, and that work is at the expense of the stream's energy. (3) Its presence reduces the mobility of the water, in effect increasing its viscosity, and thus consumes energy. For the finest elements of load the third factor is more important than the second; for coarse elements the second is the more important. For each element the second and third together exceed the first, so that the net result is a tax on the stream's energy. [illegible]

[illegible]

also, but the rates of increase are less than in stream transportation. Capacity is reduced by roughness of bed.

VERTICAL VELOCITY CURVE—The vertical distribution of velocities in a current is controlled by conditions. The level of maximum velocity may have any position in the upper three-fourths of the current. In loaded streams its position is higher as the load is greater. In unloaded streams its position is higher as the slope is steeper, as the discharge is greater and as the bed is rougher.

PITOT TUBE—The constant of the Pitot velocity gage—the ratio between the head realized and the theoretic velocity head—is not the same in all parts of a conduit, being less near the water surface and greater near the bottom or side of the conduit.

NEWS NOTES

A Ditching Machine Broke a 6-In. Water Main in Springfield, Ohio, on Aug. 27.

A Broken Water Main in Brooklyn, N. Y., flooded the new Seventh Ave. subway at 21st St. to a depth of 12 ft.

An Elevator Cable broke in a building in Philadelphia, Penn., on Aug. 28, injuring the three occupants of the car.

An Undermined Wall Failed in Toronto, Ont., on Sept. 1 and fell into the adjacent excavation for a large office building. At about 1 p.m., the side wall of the building settled, opening a crack in the front. It was immediately attempted to shore up the wall, but at 8 p.m. half of it fell.

Floods in Manila, P. I., followed a week's heavy rain. During the 48 hours ending at midnight, Sept. 1, the precipitation was 16.4 in. A message from Governor-General Harrison states that the lowest sections of Manila were flooded to a depth of 3 to 5 ft. Eight persons were drowned.

A Survey of the Street Trees of the Borough of Manhattan, New York City, is being made by the Landscape Engineer of the State College of Forestry at Syracuse. In one ward only 200 shade trees were found on 12 mi. of residential streets, or one to 110 ft.

Magnesite from California will take the place in the United States of that formerly imported from Austria, but now held up by the European War. A fleet of Jeffrey Quad motor trucks is already hauling the American product to Tidewater, Calif., for shipment through the Panama Canal.

Disbursements for Rapid Transit Subway Work in New York City from the beginning of the existing system to June 30, 1914, aggregate $100,338,171.45, of which some $48,000,000 is represented by the Interborough system now running; the remainder has been spent on the dual system under way. These figures are exclusive of real estate purchases. The total of contracts awarded for the new lines aggregated $11[illegible],918,169 on Aug. 1[illegible].

The First Liquefied Chlorine Gas Plant for Disinfecting a Municipal Water-Supply in Massachusetts was put into use on Sept. 1 at Wakefield. The town takes its supply from Crystal Lake, which, while providing a clear, sparkling water, is liable to occasional pollution. The use of liquefied chlorine gas as a sterilizing agent was recommended by Edward C. Sherman, Consulting Engineer of Boston, who is supervising the operation of the plant, which was installed by the Electro-Bleaching Gas Co. of New York. It has been under test for about six weeks and has given satisfactory results, reducing the bacterial content to very low counts. Charles A. Dean is Chairman of the Wakefield Water Board.

Protection of Pedestrians in front of a garage which motor [illegible]

American Production of Industrial Materials, formerly imported [illegible]

the U. S. Department of the Interior. Secretary F. K. Lane, on Sept. 3, called a conference of manufacturers of coal-tar, pharmaceutical and general chemical products to find out in what ways the Government could aid in supplying the present deficiency. The normal importation of coal-tar dyes alone amounts to $7,000,000 per year. There were some 25 representatives present. It was definitely suggested (1) that there should be a system instituted in this country similar to the one in England, whereby if a foreign patent is not used and manufactured within a reasonable time, it will be opened to use by American manufacturers, and (2) that a law should be passed whereby unfair competition will be cut off. This last would preclude the practice which it is alleged is now followed of selling foreign products below the costs of manufacture. It was further suggested (3) that the secretary use his efforts through the State Department to secure permission for the exportation of dyestuffs from Germany, and (4) that the wisest way to develop a great coal tar product industry in the United States was to establish a government plant whose primary purpose should be the making of nitro derivatives of coal tar and other materials needed for explosives by the War and Navy Departments. The startling statement was made that the United States today was absolutely dependent on Germany for some of the essential elements in smokeless powder, and that if Germany stopped their manufacture or prohibited export to his country, America would be helpless.

It is reported that the experimental potash plant at Searles Lake, Calif., will be arranged for continuous production on as nearly commercial basis as possible. The initial output will be five tons per day, but a plant is under construction to turn out 120 tons.

PERSONALS

Mr. Frank C. Miller has been appointed City Engineer of Sacramento, Calif., succeeding Mr. Albert Givon, Assoc. M. Am. Soc. C. E., resigned.

Mr. C. M. Buck, Assoc. M. Am. Soc. C. E., of Guthrie, Okla., has been appointed Division Engineer of the Atchison, Topeka & Santa Fé Ry., with office at Emporia, Kan., succeeding Mr. F L. Guy, resigned.

Mr. W. D. Warren, formerly Division Engineer of the New York, New Haven & Hartford, Conn., has been transferred to Providence, R. I., to succeed Mr. W. T. Spencer, Assoc. M. Am. Soc. C. E., promoted.

Prof. John C. Olson, formerly of the Polytechnic Institute of Brooklyn, N. Y., has been appointed Professor of Chemistry and head of the department of chemistry at Cooper Union, New York City.

Mr. W. J. Miller, Master Mechanic of the St. Louis Southwestern Ry. of Texas, at Tyler, Tex., has been promoted to be Superintendent of Motive Power of the company with headquarters at Pine Bluff, Ark., succeeding the late T. E. Adams.

Mr. Harrison P. Eddy, M. Am. Soc. C. E., of Metcalf & Eddy, Consulting Engineers, Boston, Mass., has been appointed Consulting Engineer of the city of Dayton, Ohio, in connection with the improvement of the sewerage system of that place.

Mr. Jamees N. Hatch, M. Am. Soc. C. E., Structural Engineer for Sargent & Lundy, Consulting Engineers, Chicago, Ill., has resigned to open an office for private practice at 1525 Old Colony Bldg., Chicago. He intends to specialize in appraisal and valuation work.

Mr. H. E. Kellenberger has been appointed Senior Signal Engineer of the Central district of the Division of Valuation, Interstate Commerce Commission, with headquarters at Chicago, Ill. He was formerly Superintendent of Signals on the Chicago Great Western Railway.

Mr. W. J. Gough, Assoc. M. Am. Soc. C. E., formerly Assistant Engineer of the Coronado Beach Co., San Diego, Calif., has been elected Vice-President and Superintendent of the Los Angeles & San Diego Beach Ry., succeeding Mr. R. B. Talbot, resigned, to engage in other business.

Mr. C. F. Yardley, Track Supervisor of the New York, New Haven & Hartford R.R., at Providence, R. I., has been promoted to be Division Engineer of the Central New England R.R., at Hartford, Conn., to succeed Mr. H. E. Astley, promoted to be Division Engineer of the New York, New Haven & Hartford R.R., at Hartford, Conn.

Mr. Harry R. Kurrie, General Attorney of the Chicago, Indianapolis & Louisville Ry., has been elected President to succeed Mr. F. A. Delano, M. Am. Soc. C. E., resigned, as noted in our issue of Aug. 20. Mr. Kurrie is 39 years old and entered the service of the Chicago, Indianapolis & Louisville Ry. in 1902 as Assistant General Solicitor.

Mr. Charles Saville, Assoc. M. Am. Soc. C. E., has resigned from the firm of Hering & Gregory, Consulting Engineers, New York City, and will spend the coming winter in Boston, Mass., taking a graduate course at the School for Health Officers at Harvard University and the Massachusetts Institute of Technology. His home address is Waban, Mass.

Mr. J. A. Lindstrand has been appointed Senior Architect in the Central district of the Division of Valuation, Interstate Commerce Commission, with headquarters at Chicago, Ill. Mr. Lindstrand was for fifteen years in the Architect's office of the Chicago, Burlington & Quincy R.R. and for the past eight years has been Architect for the Chicago, Milwaukee & St. Paul Ry.

Mr. A. H. Whiteside, former Manager of the power and electric department of the Allis-Chalmers Co., Milwaukee, Wis., has been appointed Vice-President and General Sales Manager of the Goulds Manufacturing Co., of Seneca Falls, N. Y. Mr. Whiteside succeeds Mr. W. E. Davis, who has been obliged to give up some of his active duties due to injuries sustained several months ago.

Mr. Fred M. Baumgardner has been appointed Senior Inspector of Motive Power in the Central district of the Division of Valuation, Interstate Commerce Commission, with headquarters at Chicago, Ill. His experience has been with the Mechanical Department of the Union Pacific R.R. and Illinois Central R.R., having served as Round House Foreman, General Foreman and Masted Mechanic on the latter road and having recently been made Master Mechanic at Clinton, Ill.

Mr. Fred B. Corey, F. Am. Inst. E. E., for 11 years in the engineering department of the General Electric Co., Schenectady, N. Y., and for the past three years Engineer of Inspection and Tests of the Union Switch & Signal Co., Swissdale, Penn., reporting to the General Manager, has resigned that office to open an office at 404 Arrott Bldg., Pittsburgh, Penn., as Consulting Engineer, specializing in inspection methods and organizations for manufacturing companies. He will also specialize in electric railway signaling and allied subjects.

Mr. D. K. Van Ingen has been appointed Second Assistant Field Engineer in the Central district of the Division of Valuation, Interstate Commerce Commission, with headquarters at Chicago, Ill. He was educated at Rensselaer Polytechnic Institute, and has been with the Chicago & Northwestern Ry., Choctaw, Oklahoma & Gulf R.R. and New York Central & Hudson River R.R., having been Assistant Engineer in charge of valuation work on yards and terminals in Iowa on the Chicago & Northwestern since 1913, and within the last month he was appointed Chief Draftsman in the valuation department of the same road.

Mr. W. E. Van Hook has been appointed Office Engineer for the Central district of the Division of Valuation, Interstate Commerce Commission, with headquarters at Chicago, Ill. He is a graduate of the University of Wisconsin. The first five years after graduation he was on railroad work in location, construction, maintenance and valuation work with the Chicago & Northwestern Ry., Chicago & Alton R.R., and the Chicago, Milwaukee & Puget Sound R.R. For the past three years he has been with the Illinois Railroad & Warehouse Commission and later the Public Utilities Commission of the State of Illinois.

Mr. Truman P. Gaylord, Assoc. Am. Inst. E. E., District Manager of the Westinghouse Electric & Manufacturing Co., at Chicago, Ill., has been elected Acting Vice-President to succeed Mr. H. D. Shute, promoted, as noted elsewhere. Mr. Gaylord graduated in electrical engineering from the University of Michigan in 1895. Until he joined the staff of the Westinghouse Electric & Manufacturing Co. in 1899, Mr. Gaylord was Assistant Professor of electrical engineering at the Armour Institute of Technology and with the Chicago Edison Co. He was appointed District Manager of the Chicago office of the Westinghouse Co. in 1902.

Mr. B. B. Kelliher, M. Can. Soc. C. E., has resigned as Chief Engineer of the Grand Trunk Pacific Ry. on account of ill health. Mr. Kelliher was born in Ireland in 1862 and graduated from Dublin University. He served an apprenticeship in civil engineering in his native country and in 1886 came to the United States, where for four years he was with the engineering corps of the Union Pacific R.R. For 14 years he was a railway and mining engineer in the Northwest and in the Rocky Mountain States. He joined the staff of the Grand Trunk Pacific Ry. in 1904 as Division Engineer at Winnipeg, Man., and a year later was made Chief Engineer.

Mr. W. A. Christian, M. Am. Soc. C. E., formerly First Assistant to the Chief Engineer of the Chicago Great Western R.R., has been appointed by the Interstate Commerce Commission Senior Civil Engineer in charge of the roadway and track department for the Central district of the Division of Valuation, with headquarters at Chicago, Ill. Mr. Christian graduated from the University of Cincinnati and his early work was with the Baltimore & Ohio, Chesapeake & Ohio, and C. C. C. & St. L. railroads. In 1891 he was Assistant County Engineer of Hamilton County, Ohio, and from 1895 to 1902 was with the United States Army Engineer Corps as U. S. Assistant Engineer in charge of plans and estimates for river and harbor improvements. He was then with the Big Four R.R. for about a year on maintenance work, and from 1903 to 1907 was again with the U. S. Army Engineer Corps as U. S. Assistant Engineer in charge of plans and estimates for concrete movable dams in the Ohio River. Since 1907 he has been with the Chicago Great Western R.R. as Assistant Chief Engineer.

Mr. Henry D. Shute, Assoc. Am. Inst. E. E., Acting Vice-President of the Westinghouse Electric & Manufacturing Co., Pittsburgh, Penn., has been elected Treasurer to succeed Mr. T. W. Siemon, who recently resigned to become Secretary-Treasurer of the Union Switch & Signal Co., Swissvale, Penn. Mr. Shute is an electrical engineering graduate of the Massachusetts Institute of Technology, class of 1892, and in 1893 entered the employ of the Westinghouse Electric & Manufacturing Co. as an apprentice. He entered the engineering department of the company in 1897 and a year later was transferred to the commercial department. In 1901 Mr. Shute was promoted to be the head of the alternating current division of the commercial department, and two years later was made Assistant to the Vice-President, in which position he had much to do with the development of heavy electric traction and single-phase railway work. He has been Acting Vice-President since 1910.

OBITUARY

William A. Stern, senior member of the firm of Stern & Silverman, which controls many street and electric railway properties and holds a franchise for a tunnel under the Delaware River at Philadelphia, died Sept. 4, at his home in Philadelphia. He was 54 years old.

Jacob H. Olhausen, former General Superintendent of the Central R.R. of New Jersey, died at his home in New York City, Sept. 2, aged 76 years. He entered the service of the Philadelphia & Reading Ry. as a water boy. He was successively promoted to be brakeman, conductor, and eventually Division Superintendent.

Henry Harbinson Sinclair, M. Am. Inst. E. E., a prominent electrical engineer of Los Angeles, Calif., died Aug. 31 at his home in Pasadena. He was born in Brooklyn, N. Y., 57 years ago. He went to California in 1889 and became connected with several large hydro-electric projects. He acted as consulting expert in the organization of the Great Western Power Co., of San Francisco, Calif., of which he later served as Vice-President. He was a well known yachtsman and twice the winner of the ocean race from San Francisco to Honolulu. He is survived by a widow, a son and a daughter.

Moritz George Lippert, for almost half a century connected with the drafting department of the Phœnix Bridge Co. and its predecessors, Phœnixville, Penn., died at his home in Phœnixville, Aug. 30. More than 200 young engineers and draftsmen have been trained under him as Chief Draftsman during the many years he had been with the company. Mr. Lippert was born Nov. 19, 1846, the son of [illegible] in Leipzig, Germany. He graduated from the Royal Polytechnic Institute at Dresden and for several years practiced his profession in Germany. In 1869 he came to the United States and settled in Phœnixville, where in the previous year the firm of Kellogg, Clarke & Co. had opened an office for designing and erecting iron bridges and kindred structures. This firm was reorganized in 1871 as Clarke, Reeves & Co. and 1884 was transformed into the Phœnix Bridge Co. Under the late [illegible] as Chief Engineer of Kellogg, Clarke & Co., Mr. Lippert was appointed to take charge of the drafting room, where he continued for many years. Besides his professional work he found time for many public and philanthropic activities. For many years he was the moving spirit and director of a town cooperative society for supplying groceries and other commodities. As Secretary of the local board of health he performed a vast amount of work, doing it so thoroughly that his reports became models to be followed by the health authorities of other towns. For many years he served as Secretary of the local hospital board. The local newspaper pays this tribute to his sterling qualities:

> No citizens of this country—native or naturalized—ever fulfilled all the duties of citizenship more conscientiously and more intelligently than did Mr. Lippert. Personally he had an equable temper, or under perfect control, a keen sense of justice and a saving sense of humor. He was exacting only with himself, to all others he was most lenient and most forgiving. With the formal courtesy of the old world softened by his contact with the new, he was most companionable and most lovable. He loved the world and the world loved him and will miss him.

Mr. Lippert is survived by a widow, a daughter, two sisters and a brother, F. George Lippert, Assistant Engineer of the Phœnix Bridge Co.

ENGINEERING SOCIETIES

COMING MEETINGS

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.
Sept. 15-18. Convention in Atlantic City, N. J. Secy., Clayton W. Pike, Electrical Bureau, Philadelphia, Penn.

ILLUMINATING ENGINEERING SOCIETY.
Sept. 21-25. Annual convention in Cleveland, Ohio. Secy., Joseph D. Israel, 29 W. 39th St., New York City.

RAILWAY SIGNAL ASSOCIATION.
Sept. 22-24. Annual convention in Bluff Point, N. Y. Secy., C. C. Rosenberg, Times Building, Bethlehem, Penn.

ATLANTIC DEEPER WATERWAYS ASSOCIATION.
Sept. 22-26. Annual convention at New York. Secy., Addison Burke, Philadelphia, Penn.

INTERNATIONAL IRRIGATION CONGRESS.
Oct. 5-9. At Calgary, Alta. Secy., Andrew Miller, Industrial Commissioner, Calgary.

AMERICAN ELECTRIC RAILWAY ASSOCIATION.
Oct. 12-16. Annual convention at Atlantic City, N. J. Secy., E. B. Burritt, 29 West 39th St., New York City.

NATIONAL COUNCIL FOR INDUSTRIAL SAFETY.
Oct. 13-15. Annual "Safety Congress," at Chicago, Ill. Secy., W. H. Cameron, Continental Bank Building, Chicago.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.
Oct. 20. Convention at Los Angeles, Calif. Secy., C. A. Lichty, 319 North Waller Ave., Chicago, Ill.

INTERNATIONAL ASSOCIATION OF FIRE ENGINEERS.
Oct. 20-23. Annual convention at New Orleans. Secy., James McFall, Roanoke, Va.

AMERICAN ROAD CONGRESS.
Nov. 9-14. Atlanta, Ga. Permanent headquarters, American Highway Association, Colorado Building, Washington, D. C.

International Rubber Congress and Exhibition—Among the international congresses scheduled this year and next is the Rubber Congress set for Sept. 8-Oct. 18, 1914, at Batavia, Java. Although we have not been informed of the abandonment of the Congress in view of the European war, it is quite possible this has been done. An extensive program had been prepared. The local secretary is Dr. A. A. L. Rutgers, Buitenzorg, Java.

American Peat Society—At the 8th annual meeting of the Society, held in Duluth, Minn., Aug. 20-22, the following papers were presented:

"General Drainage Work, or Reclamation of Swamp Areas," Dr. Joseph Hyde Pratt, State Geologist of North Carolina; "Latest Development in the Peat Gas Producer," F. B. Haanel, Department of Mines, Ottawa, Canada; "The Possibilities of Peat in the Beneficiation and Smelting of Iron Ores," Prof. Peter Christianson, University of Minnesota; "Converting Peat into Fuel, and the Origin and Nature of Muskeg Peat," Prof. Chas. A. Davis, U. S. Bureau of Mines; "The Peat Industry in Ireland," Thomas Tomlinson, Dublin, Ireland; "Peat Briquetting," Dr. J. McWilliam, London, Canada; "Briquettes from Peat and Petroleum," Robert Biel, Sacramento, Calif.; "Practical Demonstration of Herbein's Patent by a Small Working Model of the Herbein Briquetting Machine," C. A. [illegible], Cleveland, Ohio; "How to Prepare a Peat Bog for Fuel Making," Gustave Carlson, Farnham, Ont., Canada; "Application of Machinery on Peat Deposits," L. A. Krupp, Findlay, Ohio; "Economic Aspect of Peat in America," John N. Hoff, New York; "Reclamation of Swamp Lands of Carolina and the South Atlantic States," Prof. J. D. Wood, University of Nebraska; "Comparative Costs of Drying Peat Fertilizer with Fuel Oil and Coal," John Wiesmer. The Secretary is Julius Bordollo, Kingsbridge, New York City.

A City Managers' Convention will be held in Springfield, Ohio, Dec. 2-4. For information regarding the convention Charles E. Ashburner, City Manager, Springfield, Ohio, should be addressed.

VOLUME 72 SEPTEMBER 17, 1914 NUMBER 12

Concrete Arch Bridge with Ornamental Tile Panels, Philadelphia

By Jonathan Jones*

The city of Philadelphia has just completed a concrete arch bridge which, while it presents no structural features that are not standard in that city, is unusual in the prominence given to colored-tile panels, inserted in the concrete parapet, as a medium of decoration.

The bridge crosses the cut of the North Pennsylvania R.R., which for about a mile bisects the attractive residential district of Oak Lane. To provide for the considerable traffic which will take advantage of this crossing, and to accord with the type of dwelling characteristic of Oak Lane, this street, known at present as 66th Ave., is planned of 80-ft. width (50-ft. cartway and two 15-ft. sidewalks) and the bridge is built of full street width.

The clear span is 40 ft. and the skew about 75°, making the span on bridge axis 41 ft. 6¼ in. The clearance over outer rail of the double-track railroad is 16 ft. and the soffit curve adopted is an ellipse of 8 ft. 10⅝-in. rise.

The bridge is designed to carry as live load a 40-ton truck on any part of the roadway and 100 lb. per square foot of sidewalk. No reinforcement is used in the arch, the thickness at crown being 24 in. and the maximum stress in the concrete, 500 lb. per sq.in. No hinges are used and the six buttresses into which the arch stress is delivered take bearing on footings of a micaceous gneiss. The arch ring concrete is 1 : 2½ : 5, with the maximum possible amount (about 30 to 40%) of one-man stone embedded normal to the line of arch pressure.

The wing walls are parallel with the street, and are completely severed from the arch ring and spandrels, to prevent cracks being occasioned by the motion of the latter. The vertical joint thus formed is lined with asbestos felt to insure a separation, and is concealed by the relief of the pilasters on each side of the span. This joint is waterproofed with a coal-tar membrane, and drained with a dry-wall backing.

Fig. 1. Railing of 66th Ave. Bridge, Philadelphia, Showing Colored-Tile Inset

The spandrel wall is also cast independently of the arch ring, and after the slacking of the centers. The parapet is of solid concrete, with light reinforcement in the top to take care of slight temperature movements in the arch ring and in the parapet. The simple lines of the parapet are well brought out by the views, also the sharpness of the edges and the rough texture of the surface, which was obtained by using a ¾-in. crusher-run stone and scrubbing the next day after pouring.

On the outside, the parapet panels are recessed in the 8-in. wall. On the inside, these sunk panels are replaced by flush panels of dull-glazed Grueby tile, principally of terra

*Assistant Engineer, Bureau of Surveys, 532 City Hall, Philadelphia.

tone and such some dark green and blue. The proportion of tile area used, with the simplicity of the concrete in which it is set, makes the tile the distinctive feature of the design.

To insure the permanency of these tile inserts, it was at first intended to cast them as 3-in. reinforced slabs at the tile setter's shop, then to support these slabs in the parapet forms and concrete them solidly in place. Because, however, of the extreme difficulty of so supporting these heavy slabs as to obtain a perfect vertical curve from end to end of the bridge, and also because to wait for the slabs to cure would have delayed the concreting of the parapet until cold weather, it was decided to leave recesses in the concrete and set the tiles by the piece.

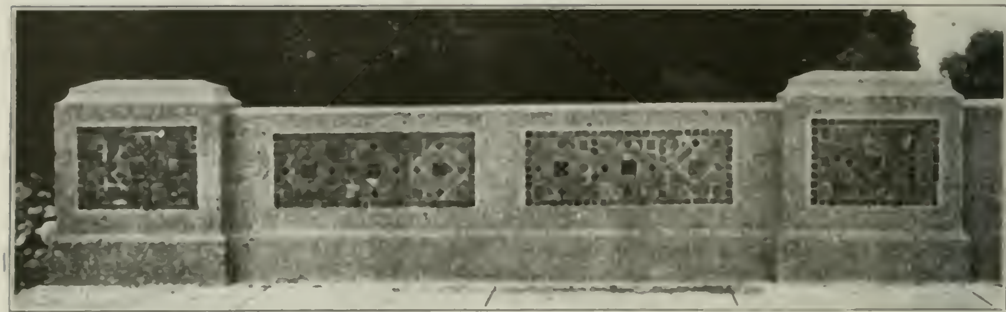

Fig. 2. Near View of Tile in Place

Fig. 3. Pilaster with Arrangements Preparing for Ceramic Tile

Accordingly, a 4-in. recess was formed in the concrete, and the form was left in place over winter as a protection to the edges, the bridge being thrown into use as soon as the back filling was completed. Clamps of 1/4-in. rods were cast in the parapet, as shown in Fig. 3, projecting into the space left for the tile backing. In the spring, when all danger from frost was over, the concrete was roughened and the clamps were laced at random with wire and the recess then filled with cement mortar to within 1 in. of the finished surface, as many panels being filled in a day as the tile setters could finish the next day. By this precaution it is felt that the slab of new material is locked to the older concrete without any reliance on adhesion, of which, however, considerable was obtained, and that in turn the tile are an integral portion of the new slab.

As there are in Philadelphia some examples of exterior tile work laid fifteen years ago with less refinement of method, it is not feared that frost or other agencies will dislodge these ornaments. To finish, the tile were pointed with neat cement, scrubbed with weak acid to remove cement stains, washed free of acid and coated with linseed oil.

The bridge was designed and the construction controlled by the Bureau of Surveys, Department of Public Works, George S. Webster, Chief Engineer; Richard Walsh was the general contractor, and the Wm. Moore Co., subcontractor for the tile work.

Some Gas-Explosion Experiments Leading to the Possibility of a New Floating-Piston Pump

By C. J. B[illegible]*

The gas-explosion experiments described below were performed in the mechanical laboratories of the University of Michigan during the spring of 1914, to see how efficient an explosion of gas and air could be made without compression of the charge previous to the explosion. The apparatus used consisted of a constant-volume explosion apparatus slightly altered to adapt it to these particular experiments. It consisted of a mixing chamber (with city-gas, water, air and sewer connections) where the desired proportions of air and gas were mixed at atmospheric pressure. An inlet tube led from this to the explosion chamber for the transfer of a charge. The explosive mixture used consisted of one volume of city gas and six volumes of air, as this proportion gave the greatest

*[illegible] Ave., Chicago, Ill.

pressure when exploding at constant volume. Knowing the volume of the explosion chamber and the proportions of the mixture, the amount of gas burned during the explosion could be found (one seventh of total amount in the explosion chamber with the above mixture). The B.t.u.'s in the city gas ran about six hundred, which gave a pretty accurate method of figuring the total amount of heat available for work during the explosion. To get the actual amount of work done during the explosion, a U-shaped pipe was fitted to the explosion chamber and in it a known amount of water was poured before each explosion. The force of the explosion was expended in shooting the water out of the nozzle at an angle of 45° with the horizontal. Knowing the weight of the water placed in the nozzle and the velocity of the water as it left the nozzle the kinetic energy of the water as it left the pipe would be equal to one-half the mass times the velocity squared; neglecting the slight friction losses in the nozzle this energy would be equal to the work done on the water by the force of the explosion. The water, as it left the nozzle, took the path of a parabola and fell some distance out from the nozzle. The velocity of the water as it left the nozzle was easily computed after measuring the horizontal distance from the end of the nozzle to the floor where the water hit. The formula used was*

$$V = \sqrt{\frac{32 s^2}{h + s}}$$

where V = velocity of water leaving nozzle in feet per second; s = horizontal distance from the floor beneath the nozzle to where the water hit, in feet; h = vertical distance from end of nozzle to floor, in feet.

Having found the nozzle velocity in feet per second, as above described, the work expended upon the water by the force of the explosion was found in foot-pounds by multiplying one-half the mass of the water by the velocity squared, dividing this result by 778 to change to B.t.u.'s, then dividing by the B.t.u.'s available in the gas burned during the explosion and multiplying by 100 gives the per cent. efficiency of the explosion.

The earlier experiments showed an efficiency of from 4 to 5%. Later, as the apparatus was improved and more suitable amounts of water were used, results showed an efficiency of over 10%.

The explosions were noiseless, the expansion being carried down to or below atmospheric pressure in ejecting the water from the nozzle as indicator cards taken of the explosions plainly showed.

There is no doubt that with improved experimental apparatus and further investigation along this line, the best results obtained by the writer could be surpassed. An efficiency of 10% surpasses the thermal efficiency of many two-cycle explosion engines now in operation and compares favorably with the thermal efficiency of many four-cycle engines under working conditions.

The success of the Humphrey gas pump has shown the possibilities of the liquid piston. Perhaps the cited results of these experiments might tend to show some commercial possibilities of a liquid piston-pumping engine which does not use compression of the charge previous to explosion. The possible advantages of such a liquid-piston pump over one of the Humphrey type would be the small initial cost and larger capacity—due to the greater number of explosions per minute. The Otto Langlen Gas Engine is a notable example of a type of gas engine which did not use compression previous to the explosion of the charge. The thermal efficiencies of the different tests of this engine ran from 14 to 17%, which compares favorably with the government tests of modern four-cylinder four-cycle engines which use compression previous to ignition of the charge.* This compression lowers the

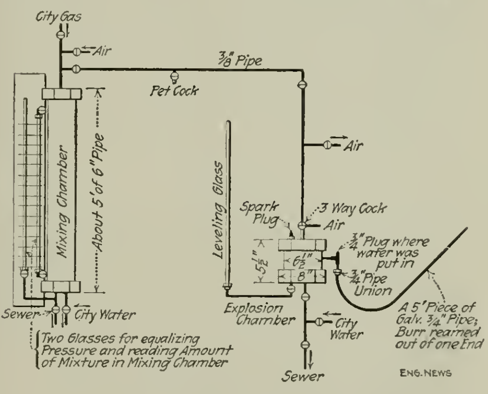

Diagram of Gas-Explosion Apparatus

mechanical efficiency and introduces thermodynamic losses.

The effect of the rate of expansion upon the efficiency of explosion is interesting. Take the two limiting cases of explosions—the first at constant volume, where the mechanical work done by the explosion is nothing and the efficiency is zero because the space is nothing.

The other limiting case is where the force becomes zero. This is illustrated by an explosion at atmospheric pressure. The force of the explosion is almost completely unrestrained, the work and efficiency of the explosion in this case is almost zero. Assume that the explosion is completely unrestrained, as would be the case if the theoretical piston could move out as fast as any increment of pressure is generated behind it, while the flame is propagated through and combustion takes place in the exploding mixture; then the force, the work done, and the efficiency of the explosion will all be zero.

The most efficient explosion will undoubtedly lie between the two limiting cases. The indicator card of the

*If V_y and V_x are the vertical and horizontal components of V, T is the time, in seconds elapsed between water leaving nozzle and reaching floor, and e is the nozzle angle with the horizontal.
Then

$$s = V_x t = V \cos e\, T$$
$$h = g/2\, T^2 - V_y T$$
$$= g/2 \frac{s^2}{V_x^2} - V_y \frac{s}{V_x}$$
$$= g/2 \left[\frac{s}{V \cos e}\right]^2 - \frac{V \sin e}{V \cos e} s$$
$$= g/2 \frac{s^2}{V^2 \cos^2 e} - s \tan e$$

For 45°

$$h = \frac{g s^2}{V^2} - s$$
$$V^2 = \frac{g s^2}{h + s}$$
$$V = \sqrt{\frac{32 s^2}{h + s}}$$

*Some later tests, reported by the Society of Automobile Engineers, on 30-hp. motors, showed thermal efficiencies running from 6 to 12%. With 85% mechanical efficiency, the overall figure would range from 5 to 10%.

-est would be represented by a straight vertical line. The indicator card in the second case would be represented on the pressure-volume diagram by a horizontal line. Theoretically, the most efficient indicator card for separate atmospheric explosions, not considering the great radiation loss during expansion, would be explosion at constant volume, followed by adiabatic expansion to atmospheric pressure.

There are so many variable factors entering here that it would be almost impossible to determine just what rate of expansion would be most efficient. It was determined experimentally in the following manner. The mixing chamber contained enough charges for several explosions. By using the same mixture for a number of explosions and keeping other conditions the same, the amount of water used in the nozzle was varied from a small to a large amount. It was found that 700 c.c. of water gave the greatest efficiencies for this particular apparatus. The smaller amounts would be shot farther but not enough farther to make the work done on the water as great as if the larger amount was used. Amounts of water over 700 c.c. would not be shot as far and the work done on the water would figure out to be less. Still larger amounts of water would almost completely deaden the explosion. The greater inertia of the larger mass of water would greatly retard the expansion of the charge to the extent that the bulk of the available energy was lost by radiation as heat.

By regulating the amount of water discharged each time, the pump could be made to operate at a rate such that the expansion would occur under conditions most favorable for the greatest efficiency. A further advantage of the liquid-piston pump of this possible type is that less time elapses during the expansion with the continuously accelerated piston than with the accelerated and retarded motion of the piston found in reciprocating gas engines. The longer time required to make a certain expansion, with the accelerated and retarded motion results in a greater radiation loss.

In glancing over some late tests made on 30-hp. automobile motors reported by the S. A. E., the thermal efficiencies ran from 6 to 12%. Assuming a mechanical efficiency of 85%, the overall percentage would range from 5 to 10%. The overall efficiency of explosion apparatus not using compression previous to ignition ranged from 5 to 10%. This is the reason that I made the statement that I thought the experiments would warrant the commercial application of the principle involved in these experiments to liquid-piston pumping apparatus.

The New High-Pressure Fire-Service System of Boston

[illegible]

Boston was one of the first cities in the United States to lay a separate pipe line solely for fire-protection purposes, about one mile of such pipe having been laid in 1898, to be supplied with salt water from the harbor by fireboats.

A general-alarm fire at Dover and Albany streets on Aug. 9, 1910, required the use of 11 fire-engines, while at the same time 18 other engines were engaged at a second-alarm fire on High St. Fifteen engines from surrounding cities rendered aid and it was evident that, in this situation, the protection of the city as a whole, as well as that of adjoining municipalities, was seriously weakened. It appeared, therefore, that steps should be taken to guard against the dangerous possibilities of a like situation in the future. After full consideration, the installation of a high-pressure fire-service system was adopted as the best and most practicable solution of the problem, in that it would furnish the most reliable form of protection to the high-value district, since it could deliver more water at high pressure than all the steam fire-engines now in the service of the city operated at one time.

The construction of such a high-pressure fire-service system became assured when a legislative act authorizing the Commissioner of Public Works to prepare the necessary plans and proceed with the construction was accepted by the city government. Upon the passage of an appropriation order by the City Council and its approval by the Mayor, on July 1, 1911, an engineering corps was organized as the High-Pressure Fire-Service Branch of

FIG. 1. JOINT FOR STRAIGHT CAST-IRON PIPE, NEW HIGH-PRESSURE FIRE SERVICE, BOSTON, MASS.

the Water Service and a consulting engineer for the pumping-station equipment was retained. The laying of the pipes has just been begun (August, 1914).

The area which will be protected by the system contains about 550 acres, comprising the whole of the 345 acres which the Underwriters term the congested-value district and adjacent territory through which it is necessary to lay pipe to serve the high-value area. For the protection of a district of this character, the capacity of the system should be such that 30,000 gal. of water per min. can be delivered about any block and 15,000 gal. of water per min. on any single building, and the system has been designed to meet these requirements.

The location of the pumping station has not yet been determined definitely, although it is very probable that it will be near Fort Point Channel, in the vicinity of the South Terminal Station, where it will be out of reach of a great conflagration. New mains will run to the station to supply the water needed for the high-pressure service, which must be ample in amount.

Motor-driven centrifugal pumps have been selected as the most reliable and economical type of equipment to install. Electrical energy will be supplied, over duplicate circuits, from the power plants of the Edison Electric Illuminating Co. Each pump will be capable of delivering

3000 gal. per min. at a pressure of 300 lb. per sq.in. Separate fireproof rooms containing the high-voltage electrical apparatus will be located in the rear of a switch-

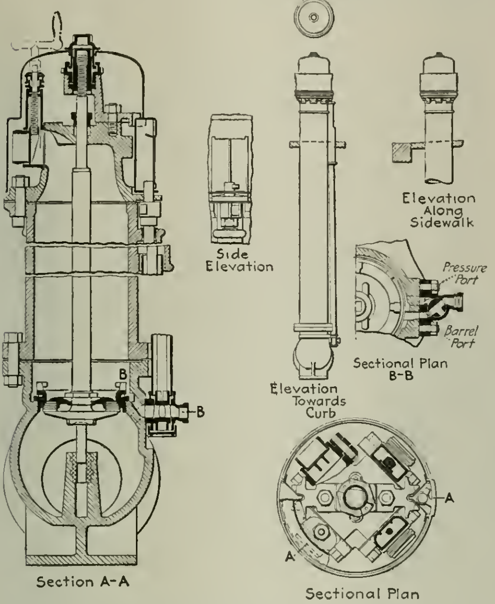

Fig. 2. Hydrant for New High-Pressure Fire Service, Boston, Mass.
(Patent applied for by J. A. Rourke*.)

board from which the pumps and motor-operated valves will be controlled. Fire alarms and orders from the Fire Department will be received over a fire-alarm circuit and a separate signal system which will be installed. Telephone service, over dupicate wires, will be provided by the telephone company.

A duplex distribution system, composed of two independent pipe systems with their mains on alternate streets, has been designed, thus insuring continuity of water-supply in case of the failure of a main in either leg of the system. About 13 miles of pipe, from 12 to 20 in. in diameter, will be required to build the system and cast iron has been selected as the best material for the purpose.

The first high-pressure systems were laid with steel pipe but cast iron was quite generally adopted later, flanged joints being used. Such joints occupy considerable space and are undesirable in streets so crowded with underground structures as are those of Boston. The selection of a bell-and-spigot pipe of special design, the details of which are shown in Fig. 1, followed an exhaustive series of tests on pipes and joints made by the Public Works Department. These tests included joints made with lead and with various alloys of lead, antimony and tin. It was found that an alloy consisting of 96% lead and 4% antimony afforded the necessary holding strength, but that a tight joint could not be made with it. The best results were obtained with 96% lead, 2% antimony and 2% tin, a joint resulting which held a pressure of 600 lb. per sq.in. on a 20-in. plug with no leakage. This alloy was therefore adopted for all joints adjacent to branches, offsets, bends and dead ends where holding strength is necessary. The specifications require that the alloy shall be made by melting the lead in a large pot, adding the proper proportion of antimony, previously melted in a separate pot, and then adding the tin.

*J. A. Rourke is Mechanical Engineer, High Pressure Fire Service, of the Public Works Dept. of Boston.

All pipes, after laying, are to be tested by water pressure at 400 lb. per sq.in. and the leakage must not exceed ½ gal. per lin.ft. of pipe joint per 24 hours.

The mains will be so equipped with gate valves that a break in a pipe will necessitate putting out of service not more than three hydrants and each valve will be set in a manhole large enough to permit of easy access for maintenance and repairs. The valves are of special design, made to suit the requirements of the service.

The hydrant adopted, shown in Fig. 2, was also designed in the Public Works Department. It is simple in design, reliable and efficient, and has a capacity of 2000 gal. per min., which is equivalent to that of three fire engines. Each hydrant will be set on a branch provided with a gate valve, as shown in Fig. 3, thus providing for cutting out any hydrant without affecting the flow in the mains. About 450 hydrants will be placed within the area covered by the system, or about one hydrant to each 40,000 sq.ft. of area, which will enable the capacity of the system to be concentrated where needed through hose lines of moderate length.

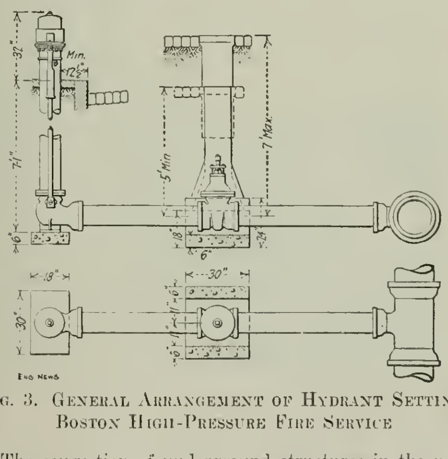

Fig. 3. General Arrangement of Hydrant Setting, Boston High-Pressure Fire Service

The congestion of underground structures in the narrow streets makes the work of laying the high-pressure pipe very difficult. To enable the work to be done to the best advantage and at a minimum expense, plans have been made, based on a transit survey, showing all existing structures and enabling the selection of the most feasible locations.

The high-pressure fire-service system will enable a large number of powerful streams to be concentrated on a fire in a shorter time than with fire engines, and with much fewer men and less apparatus. This will, in turn, enable the protection of the remainder of the city to be maintained during the progress of a fire in the district covered by the system in addition to providing ample protection to the highest values in the city during the progress of a possible conflagration in the congested, frame-structure, residential districts.

The New Girard Point Grain Elevator at Philadelphia

By S. Ingberg*

SYNOPSIS—The new Girard Point grain elevator of the Pennsylvania R.R. at Philadelphia has concrete bins, with a total capacity of 1,078,700 bushels. The foundation consists of piles capped with a large reinforced-concrete slab, with a waterproofing course. The basement being below high-water level, the lower ends of the elevator boots are enclosed in steel tanks as an additional precaution against water. All machinery is electrically operated. One of the interesting features of the article is the description of the way in which the grain is handled from the time it is removed from cars until it is shipped for transportation.

A large terminal grain elevator for transfer and storage purposes has been erected at Girard Point, Philadelphia, for handling the export business of the Pennsylvania R.R., as the traffic overtaxes the present facilities. It is located at the mouth of the Schuylkill River, and was built for the Girard Point Storage Co., which is a subsidiary of the railway company.

The general plan of the plant is shown in Fig. 1, and Fig. 2 is a view of the buildings when practically completed. The cross-section and plans in Fig. 3 show not only the design and construction, but show also the arrangement of the conveyors and other apparatus for handling, weighing and distributing the grain. The loaded cars are delivered to a large yard (at the left of Fig. 1) having 12 tracks, spaced 13 ft. c. to c. and on a descending grade of 1% toward the elevator. These converge into six tracks extending to the elevator.

The track shed where the grain is delivered from the railway cars is 144x144 ft., with six tracks spaced 20 ft. c. to c. Adjacent to this is the working house 92x144 ft., from which a conveyor bridge extends along the dock to deliver grain to vessels. Above the first floor of this building are 29 cylindrical concrete bins 13 ft. diameter and 74 ft. high, and above these is the cupola, 62x82 ft., and 93 ft. high, containing the distributing machinery, etc. The storage house consists of 51 cylindrical bins 15 ft. diameter and 96 ft. high, surmounted by a working floor for the conveyor belts which deliver grain to the bins. Provision is made for increasing the size of the plant when required.

The working house, with its track shed and conveyor gallery, has a capacity for storing 240,000 bu., receiving 28,000 bu. per hr., shipping 60,000 bu. per hr. from the dock, and cleaning and separating 10,000 bu. per hr. The storage house has a capacity of 837,000 bu., and the dryer has a capacity of 3000 bu. per hr. It should be noted that one of the bins of the working house is utilized for a freight elevator and spiral stairway, and is not available for grain. The details of the bin capacity are as follows:

Total		[illegible]
Grand total		1,078,700

STRUCTURAL FEATURES

The structures are of reinforced-concrete throughout, with the exception of the steel gallery for the dock conveyors. Borings at the site showed about 50 ft. of mud and clay, followed by gravel and sand to about 60 ft., with rock at two points 64 ft. and 101 ft. from the surface. The foundation is a reinforced-concrete slab (with side walls rising above water level), supported on wood piles 60 ft. long. These piles carry an average load of 16 tons,

*Structural Engineer, James Stewart & Co., Chicago.

and under the working house and the storage annex they are spaced 27 in. c. to c. in each direction.

The bottom foundation slab and foundation walls are waterproofed with a 6-ply felt membrane cemented with a pitch compound. This membrane extends 6 in. above the extreme high-water line; it is underlaid with 9 in. of concrete and on the outside of the walls it is protected by 5 in. of brick. As a further precaution against the water, which at times comes 3 ft. above the basement floor, there is a system of inside drains laid in the basement slab and emptying into the boot pits. In the latter, one on each side of the house, is located a sump served by an automatic motor-driven pump, the operation of which is controlled by a float. This, with the use of water-tight steel tanks around the boots, is thought to insure the operation of the elevator during periods of extreme high water and to prevent stagnant water from collecting in any portion of the building.

THE WORKING HOUSE—Fig. 1 shows the construction of the slab under the working house. The depressions for the boot tank ($8\frac{1}{2}$ ft. on the receiving side and $6\frac{1}{4}$ ft. on the shipping side) were filled with sand after the steel tanks were placed, and the fill covered with a 4-in. concrete slab.

Fig. 4 shows also other details of the working house, a cross-section of which is given in Fig. 3. Its columns (the larger of which are loaded to 1,500,000 lb.) are reinforced with spiral hooping and vertical rods, as are also those in the first story. The latter are shown in Fig. 4, together with a plan of the girders and slab supporting the bins. The walls of the bins are 6 in. thick (7 in. on the exterior side of the outer bins). The reinforcement consists of vertical bars and horizontal hoop bands, the latter spaced 12 in. vertically. Each band consists of two semicircular bars, with overlapping ends, the bands breaking joint in the several courses.

THE STORAGE ANNEX—This building (at the right in Fig. 3) has its bins or tanks supported on a 16-in. top foundation slab bearing on piers, two for each tank, as shown in the foundation plan on the same cut. The bottom slab, 4 ft. in total thickness, is reinforced with bands of bars in the top and bottom. The bands in the bottom are laid in two directions and under the piers, while those in the top are laid in four directions, directly and diagonally between the piers. The 16-in. upper slab has four-way reinforcement, supplemented by circular bands around the openings for the draw-off hoppers at points of maximum tension and compression. The bottom foundation slab was made heavier than the stress requirements would demand, on account of the desirability of placing the basement floor above mean high water without the use of a false floor.

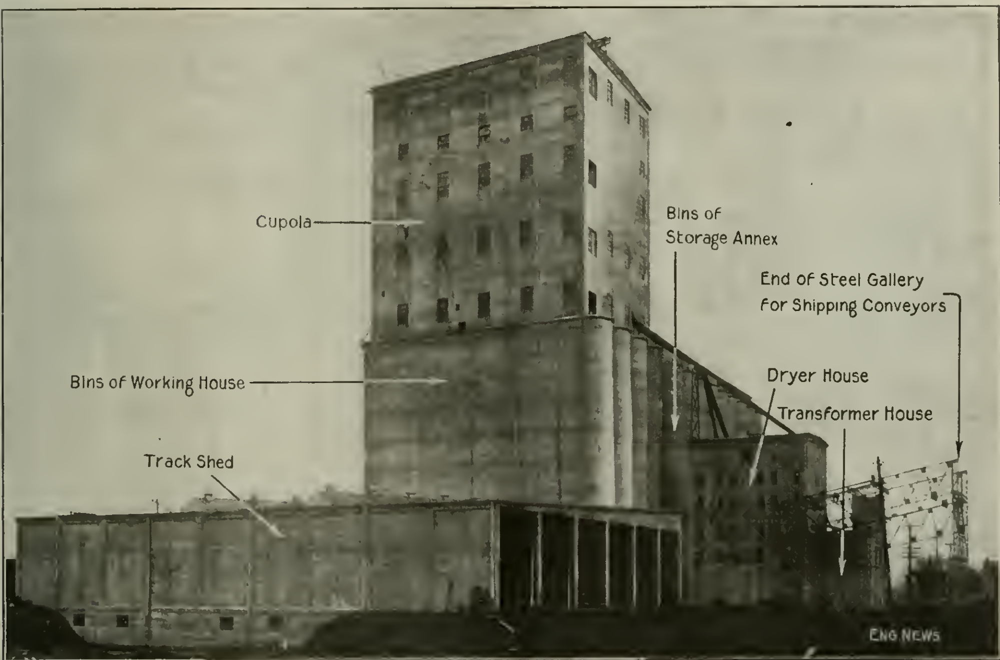

FIG. 2. COMPLETED BUILDINGS OF THE GIRARD POINT GRAIN ELEVATOR

The circular reinforcement for the tanks consists of flat bars ($1\times\frac{1}{4}$-in. to $1\times\frac{1}{8}$-in.), spaced 12 in. apart. Each band is made up of two lengths, lapping $3\frac{1}{2}$ in., each band breaking joints with those above and below it. No mechanical means are employed for bonding the two pieces other than the concrete, which has a minimum thickness of $1\frac{1}{2}$ in. between the bars and with a fair unit-bond stress forms an efficient joint.

FORMS—The bins and the working-house cupola were built with moving or sliding forms. These are composed of vertical staves 4 ft. high, nailed to circular chords made up of 2x8-in. planks cut into segments. They are

moved up by screw jacks working on the vertical jacking bars embedded in the bin walls. The jacks and yokes are shown in place in Fig. 5. This method of forming is not only found to effect an economy in time and expense, but also to give a smoother surface than is ordinarily obtained with stationary form work.

Conveyor Bridge.—The bridge or gallery (Fig. 1) extending along the dock, and carrying the shipping conveyors, consists of an inclined portion 300 ft. long in six spans of 50 ft., leading up from the working-house gallery to tower No. 1, and a level portion between the towers 660 ft. long in 11 spans of 60 ft. In the towers are the motors and drives for the four 36-in. belt conveyors contained in each portion of the bridge. The [illegible] construction of the bridge is shown in Fig. 6. It has two side trusses carrying the floor at their lower chords and a center truss beneath the floor. The trusses are of similar design except at the end connections. The [illegible] of the center truss are carried into the columns by means of a triangular end truss consisting of double-channel struts riveted to the columns. The arrangement of trusses [illegible] the ends of the floor beams and leaves a clear space above the floor for the conveyors.

The floor beams consist of 15-in. channels [illegible], and on these are laid the T-bars for receiving the book-tile floor (Fig. 6). The tiles are 3x12x18 in. and are covered with a 1-in. cement mortar finish. The roof is made similar to the floor except that the beams have single flanges with laced web, and the book tile is covered with 1-in. mortar finish, on which is laid a 5-ply composition tar, felt and gravel roof. The sides are covered with No. 22 galvanized corrugated siding.

Construction Plant

Sand and gravel from barges in the slip are unloaded by a clam-shell bucket into a receiving hopper discharging onto a conveyor, as shown in Fig. 7. This leads up an incline to a maximum height of 45 ft. for discharging into the stock piles, the sand being discharged by a stationary tripper 10 ft. from the end of the belt where the gravel is discharged. Trains of 1-yd. charging cars are run successively past the sand, gravel and cement, the proportioning of the aggregate being effected by marks placed on the sides of the cars. They are then run to the charging tower, and hoisted and discharged into the latter.

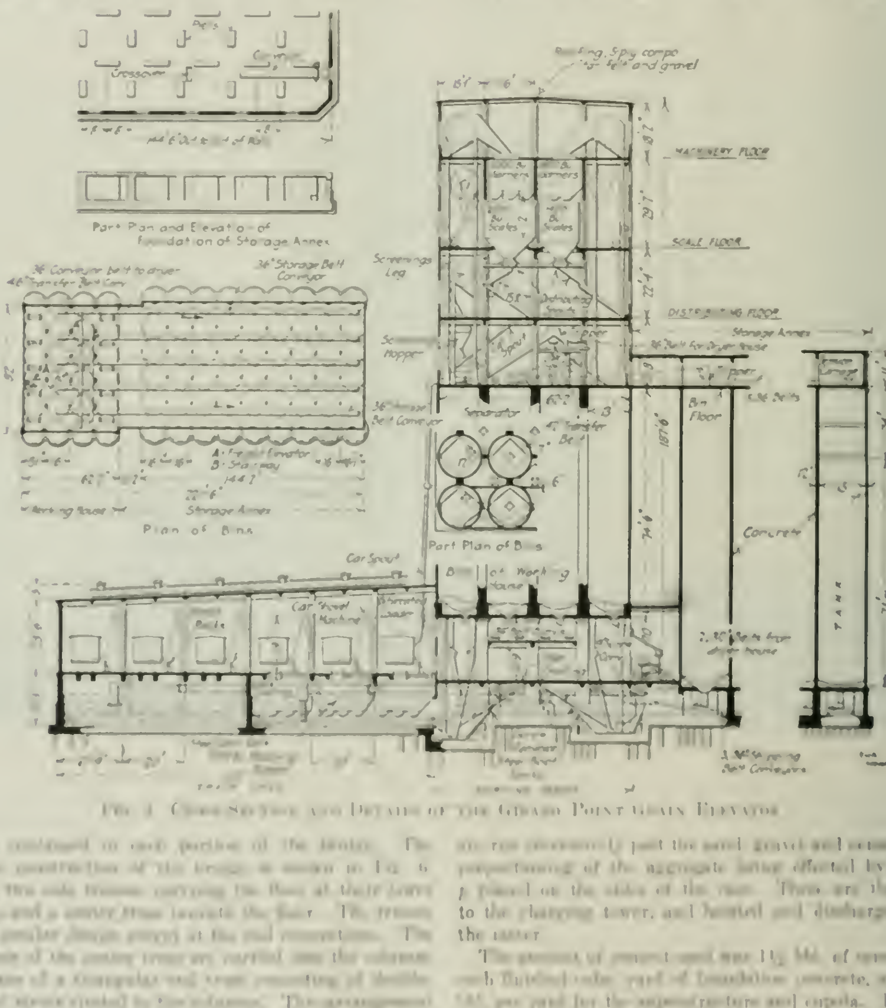

Fig. 4. Cross-Section and Details of the Girard Point Grain Elevator

The amount of cement used was 1½ bbl. of cement for each finished cubic yard of foundation concrete, and 1¾ bbl. per yard for the superstructure and cupola. Enough sand was used to fill the voids in the gravel, plus 5%. The concrete was mixed to a fluid consistency and spaded in place to avoid the formation of pockets. The aggregate being taken in by barge was subject to irregular delivery due to stormy weather, thus making it necessary to use stock piles.

Two hoist towers were erected for hoisting the gravel

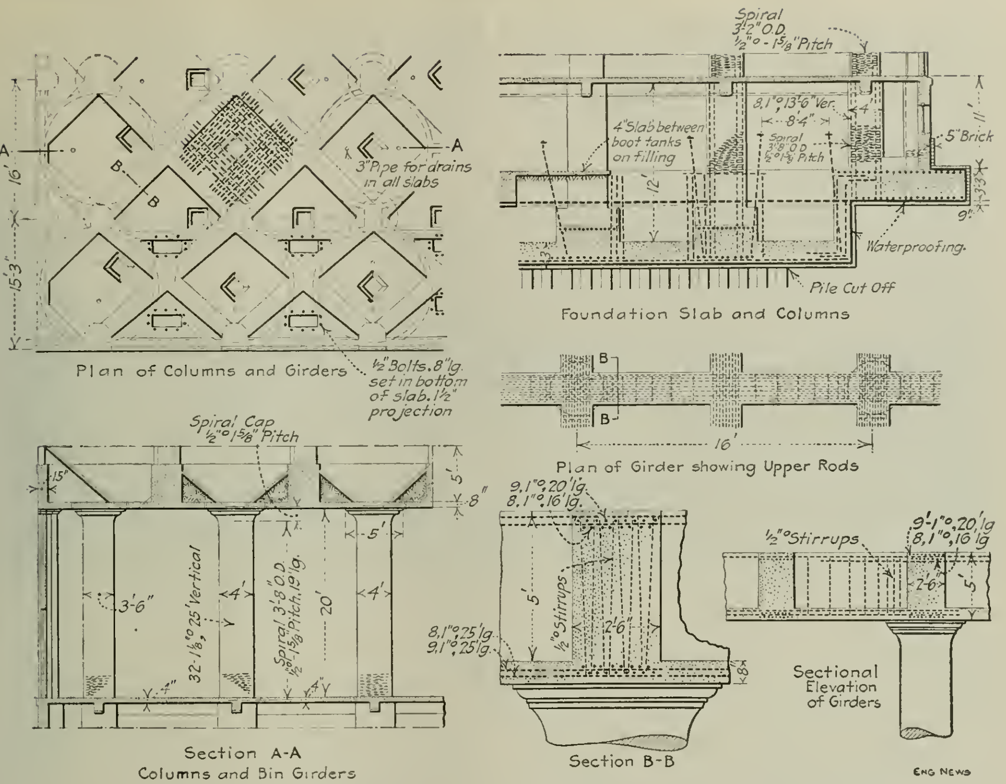

FIG. 4. DETAILS OF THE WORKING HOUSE OF THE GIRARD POINT GRAIN ELEVATOR

concrete, one serving the storage tanks and the other serving the working house, track shed and dryer house. A 1-yd. storage hopper receives the concrete from the hoisting bucket and serves the push carts used for depositing it in the forms.

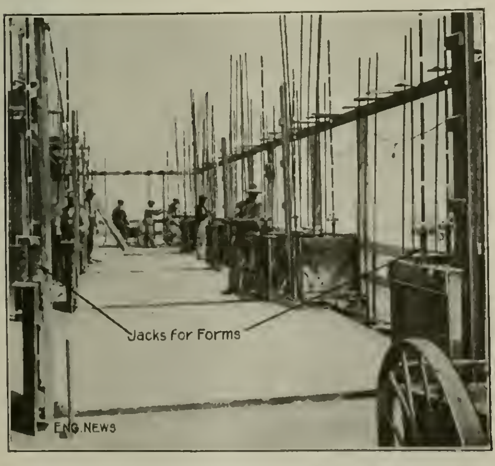

FIG. 5. REINFORCING AND JACKING RODS OF THE ELEVATOR BINS, WITH SCREW JACKS FOR RAISING THE FORMS

The job was organized and material received in October, 1912. The pile-driving contract was finished by February, 1913, and all concrete was laid from April to October following. The greatest number of men employed at one time was 350, with an average of 250 during the concreting season. The progress and the results in quality and finish of concrete attained with both moving and stationary forms were exceptionally good. As much as 10 ft. of vertical rise per day was made with the moving forms.

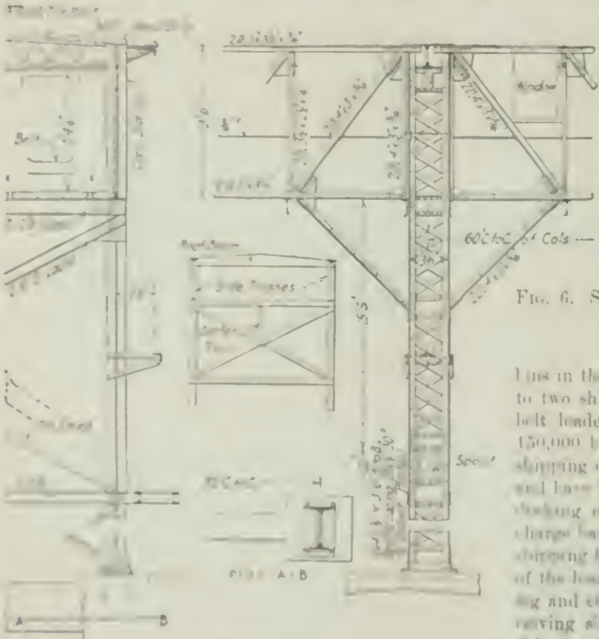
OPERATION OF THE ELEVATOR

RECEIVING—Grain is received from cars on six tracks in the track shed (Figs. 1 and 3), and each track crosses two receiving pits. The cars are hauled to and from the pits by cables operated from a six-drum car-haul machine in the north pit. At each pit is a power shovel (supported from the track-shed columns) which can unload at the rate of a car in 15 min. This is a plow hauled by a cable and drum and handled by a man in the car. The whole operation of spotting the car and unloading requires an average of 30 min. The gain drops into a 2000-bu. receiving hopper from whence it is spouted on the receiving belts. The slides under these hoppers are operated by an interlocking lever mechanism so designed

as to allow only one hopper to discharge on the belt at any one time. The receiving hoppers rest on ledges formed in the concrete walls of the track pits.

There are four 36-in. receiving belts (one for each battery of receiving pits), each having a rated capacity of 15,000 bu. per hr. and each discharging into a receiving leg of equal elevating capacity. The receiving belts and the lower portion or boot of the elevating legs are inclosed by the waterproof steel boot tanks. Noted above that the receiving legs and the shipping legs can be used for shipping. The receiving and shipping legs have rope drives connected to 125-hp. motors. The 32-in. elevator belt has two rows of 15x8-in. buckets placed 13-in. c. to c. vertically.

The grain is discharged into the receiving garners (Fig. 5), each of 2000-bu. capacity. These have concrete sides and steel hopper bottoms with nine discharge openings which afford means for quickly and evenly filling



the scale hoppers. The latter are also of 2000-bu. capacity, supported on the scale levers, and each discharges through a rotary valve into movable spouts. Each spout has two rotary joints which enable it to be doubled back upon itself, so that each spout commands an annular area on the distributing floor whose radii are the lengths of the spout when extended and doubled back.

There are 108 spout holes in this floor, from which spouts lead as follows: (1) to the working house bins; (2) to the five 36-in. belt conveyors discharging into the storage bins; (3) to the 42-in. reversible transfer conveyor on the gallery between the bin floor and the distributing floor, the tripper spout on this conveyor discharging the grain into spouts leading either to the working house bins or upon the conveyors running to the storage bins; (4) to the car spout which leads down the side of the house into the track shed and can be used for loading cars standing on the first track; (5) to the 36-in. dryer belt (on the gallery beside the transfer conveyor), discharging into a swinging spout or turnhead which can deliver to any one of the four spouts leading to the dryer house.

This system of spouting makes it possible to reach any bin in either the working house, storage annex or dryer house from any one of the nine scales, besides affording facilities for direct loading into railway cars. To reduce the number of spouts, most of them are made compound, having one or two openings in the distributing floor and another for the tripper spout (of the transfer conveyor) at the gallery floor. The belts over the storage tanks are so placed that one conveyor can serve two rows of circular bins or the row of interstice bins directly under the conveyor. Fig. 8 is a view of this floor with the conveyors and trippers and the spout holes.

SHIPPING—The 12-in. circular bins and 15 interstice

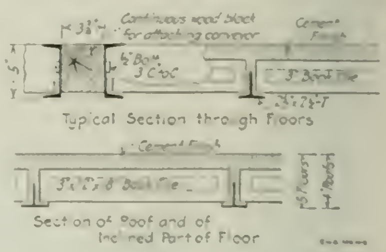


FIG. 6. STEEL BRIDGE OR GALLERY FOR THE SHIPPING CONVEYORS

bins in the center of the working-house group can deliver to two shipping belts by means of turnhead spouts and belt loaders. These bins have a combined capacity of 150,000 bu. and as the receiving ends of the four dock-shipping conveyors are under them it is possible to weigh and have in readiness an average cargo in advance of the docking of the ship. These central bins can also discharge back into the boots of the adjacent receiving and shipping legs. The six circular bins on the shipping side of the house can discharge into the boots of one receiving leg and either of two shipping legs, and those on the receiving side can spout into two receiving legs and one shipping leg.

Grain is drawn from the storage annex by means of the three 36-in. belt conveyors in the basement, each discharging into one shipping leg. These are similar in design and capacity to the receiving legs. The belts and draw-off spouts are located so that each belt receives grain from two rows of circular bins and one or two rows of interstice bins. The spouting of grain in the cupola from the shipping legs is similar to that from the receiving legs (already described) except that the shipping scales are of 1400 bu. and the shipping garners of 1800-bu. capacity.

The grain to be shipped is discharged into either one of the 77 working-house bins which spout directly onto the four 48-in. shipping belts running on the inclined portion of the bridge to the first tower. Here they rise and discharge onto the four 36-in. conveyors extending the full length of the level portion of the bridge (660 ft.)

and serving the dock spouts. The first six of these spouts deliver to the east side only, there being a berth on this side only, as shown in Fig. 1. The others deliver on both sides, as ships can lie on both sides of the outer portion of the dock. In either case, the dock spouts can be supplied from any one of the four conveyor belts by means of the compound spouts under the trippers.

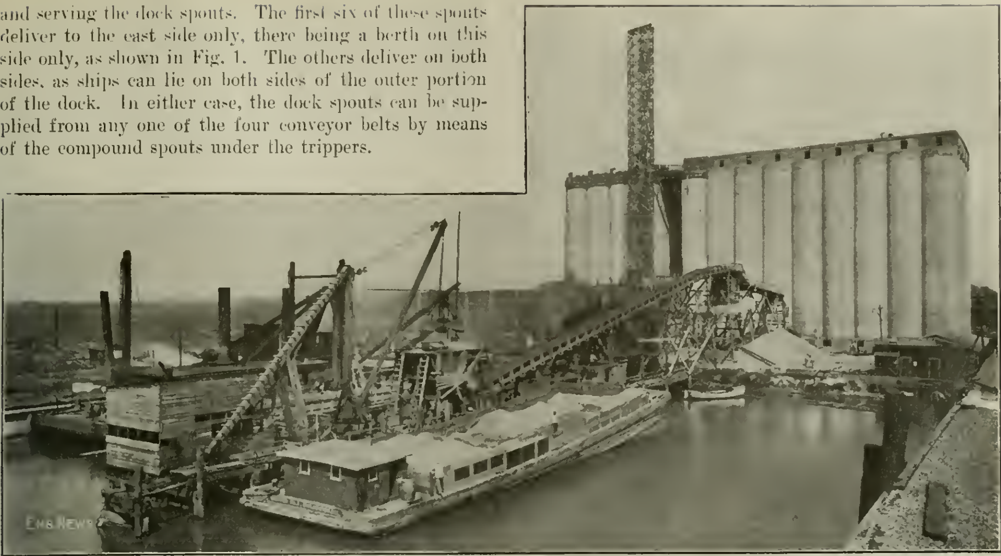

Fig. 7. Supply and Construction Plant for the Girard Point Elevator

The clam-shell derrick unloads concrete material from the barges to a hopper feeding an inclined conveyor, which delivers the material to stock piles. The concrete is raised in the tower and dumped into wheeled buckets for distribution to the forms.

These dock spouts are 66 ft. 7 in. above the dock (or 71 ft. 9 in. above mean high water) and have an extreme horizontal reach of 60 ft. when inclined 9 on 12, as shown in Fig. 9. This enables them to load the largest boats and to load into the farther of two ordinary vessels placed side by side. The channel and slips have been dredged to a depth of 35 ft. below low water.

Cleaning and Drying—The space between the working house and storage house is utilized for cleaning grain and handling grain from the dryer. There are four separators, each pair with a capacity of 10,000 bu. per hr., discharging the clean grain into two elevator legs. The screenings are delivered by screw conveyors to a leg which elevates them to a hopper on the distributing floor, from which they are fed to a second separator on the bin floor. This latter will handle 4 to 6 tons per hour. The valuable portion of the screenings is discharged into the working-house bins, while the coarse matter and dust are delivered to one of these bins which is used as the dust bin of the dust-collecting system.

The cleaner legs are utilized also for elevating the grain from the dryer, the belts from which discharge into these legs. The grain to be dried is spouted from any one of the receiving or shipping scales onto the 36-in. dryer conveyor on the gallery above the bin floor at the end of which is the turnhead for discharging into the spouts leading to the dryer house, as described above. The house has four units, each of 750-bu. capacity. From the garners the grain is charged into the dryers, the air for which is driven through the steam coils of two heaters located in the center panels on the same floor by two motor-driven fans located below them on the cooler floor. After drying, the grain is passed through the coolers and into the discharge hoppers located under them, from whence it is spouted onto either one of the dryer belts by means of compound belt-loading spouts.

The dust-collecting system is operated by two fans. A fan on the machinery floor collects the dust from the floor-sweeps in the cupola, the garners over the scales and the cyclone chamber over the screening separator, and discharges it into a cyclone located over the screenings bin. The other fan is on the first floor, taking the dust from the basement and first-floor sweeps and the four cyclones connected with the cleaning machines, and discharging it into the cyclone located over the screenings bin. There are 4 floor sweeps in the basement of the working house, 8 in the track-shed, 12 in the storage annex, 2 on the first floor and each of the cupola floors of

Fig. 8. Interior of Conveyor Floor above the Bins of the Storage Annex

There are five 36-in. conveyor belts, each with a traveling tripper to deliver the grain from the belt to the various spout holes in the floor.

the working house and one at the end of each of the five storage conveyors over the storage annex. The system is capable of taking dust simultaneously from all the dust collectors for the cleaning machines, garners and eight floor sweeps.

MISCELLANEOUS EQUIPMENT—The working house has a 1200-lb. freight elevator, extending from the first floor to the machinery floor, and there is also a spiral stairway, both occupying one of the bins. An elevator for tickets extends to the scale floor. An inter-communicating telephone system connects all parts of the plant, each instrument being arranged so that it may call any other, and two instruments are so equipped that they can ring all telephones simultaneously to call the superintendent or foreman at any part of the plant. Speaking tubes extend between the bin floor and scale floor, and communication between the shipping conveying gallery and the scale floor is had by means of electrical signal bells. A double-lamp signal (red and green) for each elevator leg is located on the first and scale floors, and a similar [illegible] signal system affords communication between the men unloading grain from the tracks and those operating the machinery on the first floor.

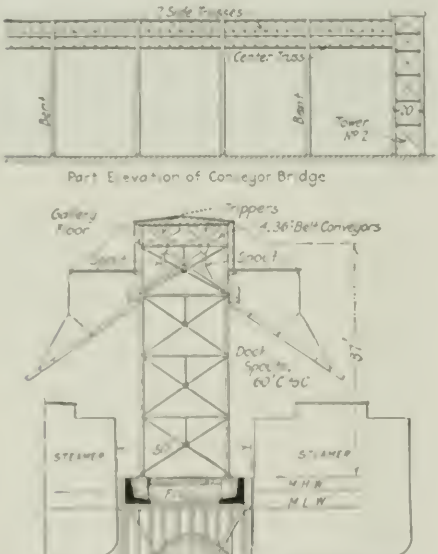

FIG. 9. CROSS-SECTION OF SHIPPING GALLERY AND PIER OF THE GIRARD POINT GRAIN ELEVATOR, PHILADELPHIA, PENN.

POWER EQUIPMENT

Current is received from the Philadelphia Electric Co. through three high-tension leads coming into the tower of the transformer house built in connection with the dryer house. The voltage is stepped down from 13,200 to 440 for the motors and 220 for the lighting system. There are 30 motors (2105 hp.) of the induction type, three-phase, 60-cycle, and wound to operate at constant speed. They are provided with starting compensators of such capacity as to start the motor under light load without requiring more than 50% excess current. As dust explosions are frequently caused by the passing of an electric spark through a dust-laden atmosphere, the entire installation is so designed that no circuit can be made or broken in the open, and precautions are otherwise taken so that no circuit can be broken due to accumulations of dust.

In general, the machinery for a grain elevator consists of relatively few but massive parts, but these must be proportioned to withstand heavy wear. The item of machinery whose adaptation has more than anything else made possible the modern grain elevator, is the conveyor belt. The belts for the receiving, shipping and cleaner legs are made of 6-ply 32-oz. duck, having the several plies cemented together with rubber compound. The outside is covered with a $\frac{1}{32}$-in. coat of rubber, vulcanized and finished. The conveyor belts are similarly made in 4-ply. The stretch in the belts is provided for in the case of the elevator belts by giving the bottom or boot pulley vertical travel in a slotted bearing frame; and in the horizontal conveyors the end or tail pulley is mounted on an adjustable frame giving it a 3-ft. travel. The head or driving pulley is connected to the motor through a countershaft to reduce the speed.

Rope drives are used almost exclusively, the manila transmission rope varying from $\frac{7}{8}$ in. to $1\frac{1}{4}$ in. Tension carriages are chiefly of the vertical finger-guide type with tension weight varying with the rope from 200 to 300 lb. and a travel of $1\frac{1}{2}$ to 2% of the total length of rope in the circuit. Bearings in the form of pillow blocks are of the spherical ball-and-socket type, ring oiling and dustproof, whereas floor stands are made rigid. An automatic journal alarm system has connections to all bearings except the conveyor roller bearings.

ENGINEERS AND CONTRACTORS

The elevator was designed and built by the grain elevator department of James Stewart & Co., of Chicago, of which department R. H. Folwell is Chief Engineer, and W. R. Sinks is General Manager. J. S. Johnson had charge of the construction work for the contractors. W. H. Cookman is architect for the Girard Point Storage Co., and its engineer is A. C. Shand, Chief Engineer of the Pennsylvania R.R.

Electric Lights for Use in Gas Charged Rooms should be low candlepower [illegible] lamps, according to tests made by the Bureau of Mines. These tests showed that when incandescent lamps of high candlepower were broken in an atmosphere charged with inflammable gas, the gas was ignited in a large proportion of the cases. Tungsten lamps ignited the gas in [illegible] to [illegible]% of the tests. The 8 candlepower, 110-volt carbon incandescent lamp, however, caused only one ignition in twenty tests, and this was a test made by breaking the tip from the bulb and allowing the gaseous mixture to enter in a small stream which did not break the filament. For additional safety it is recommended that wiring for electric light where gas is present should be installed in iron pipe conduits. If switches are used where gas is liable to be present the switch boxes should be made gas-tight. As an additional safeguard the incandescent bulbs may have heavy glass outer globes and metallic shields outside.

A Land-Drainage Problem in Missouri

By Charles H. Miller*

The St. John Levee & Drainage District, in the southeast section of Missouri, embraces the greater part of New Madrid and Mississippi counties, with a total area of 315,000 acres. It must provide for the drainage of an area of 425,000 acres (all of which should be included eventually in the district), bounded on the north by the Commerce Hills, on the west by the Sikeston ridge, and on the east and south by the Mississippi River. Part of this (40,000 acres) is now included in two smaller districts having outlets direct to the Mississippi River.

The first dredges were operated about 25 years ago, when land could be bought at $1.25 to $4 per acre. Since then, 15 drainage districts and 4 levee districts have been organized under the county-court law, and several hundred miles of ditches and 50 miles of levees have been built. The prices of these lands now range from $15 to $125 per acre. A map of the district, with the present and proposed works, is shown in Fig. 1.

Although it is probable that the St. John district eventually will take over and handle all the drainage and levee work, this cannot be done yet because of the many legal and political complications. The present aim of its managers and engineers therefore is to hurry the completion of the levee system; agreements have been made with the several levee districts as to where the work should be done, and each district will handle its part of the work to conform to the general scheme.

There will be much more difficulty in effecting an equitable consolidation of the several drainage districts. Some of these have purchased right-of-way and have constructed proper outlets, but many others have not done this. They all owe their existence to the county courts, and naturally one county will not be much concerned as to results outside of its boundaries. As some of these districts have been operating for many years, it is difficult to convince the landowners therein that they still owe something to the owners lower down, or that they should assist in the work of providing a different outlet for the surface waters.

A large part of the problem at this time is to control this drainage work and the levee work (without actually taking it over); continuing it so as to bring about one economical and complete scheme for the whole territory, and getting the different boards and interests to patch up their old differences and to work together in enlarging and extending the improvements. The scheme at this time is to provide only the levee work and the main trunk drainage.

In the reclamation of the overflow lands of the Mississippi Valley the real difficulties are more largely legal than engineering, and are brought about by the many political subdivisions that usually exist in one drainage district, we having as yet failed to reach that stage of progress where in the consideration of large public improvements we can wholly eliminate petty political jealousies.

Existing Conditions

Practically all the runoff from the entire territory passes into the Mississippi River through three channels (two natural and one artificial): James Bayou, St. John Bayou, and Lee-Rowe ditch. Connecting this ditch directly with the river was an ill advised proceeding, as an efficient outlet could have been secured at much less expense through James Bayou, and we would not be confronted at this time with the necessity of closing the mouth of this ditch. There is much sandy soil in this district, except in the lower portion.

In this territory there has been expended over $2,000,000 in reclamation work, and many drainage ditches have been constructed (mostly in the upper portions of the district). In addition, there is a line of levee (approximately 55 miles) along the Mississippi River extending to the south end of Mississippi County. This must be enlarged in order to afford reasonable protection to the land, practically every acre of which lies below the grade

Fig. 1. Map of the St. John Levee and Drainage District in Missouri, Showing the Present and Proposed Works

line here, and of course much below the grade line further up the river; and hence is always subject to overflow from a break in the levee, especially if the flood is of long duration.

Because of breaks near the upper end of the levee, during the floods of 1912 and 1913, approximately 300,000 acres were overflowed. Had the levee remained intact its entire length, then only about 190,000 acres would have been overflowed, this embracing the area now subject to back-water overflow from the head that obtains at the lower end of the levee in Mississippi county. This head can be reduced about 6 ft. by constructing an interior ditch to carry to St. John Bayou the waters from James Bayou and Lee-Rowe ditch, thus permitting the closing of their present mouths so that the levee can be extended

*President, Miller Engineering Co., Southern Trust Building, Little Rock, Ark.

[illegible] and on to the mouth of St. John Bayou. Then only about 140,000 acres will be subject to back-water overflow or are so situated as to be below the high-water mark at New Madrid, thus requiring pumping for final reclamation.

Although practically every acre of this district is subject to overflow, fully 285,000 acres are so situated as to be above back-water overflow that would enter at the mouth of the St. John Bayou. Therefore, it is possible to drain these lands by gravity and without pumping by simply constructing a high-level collecting ditch and discharging the waters into the river between levees that are above high-water stages. The recent high waters have demonstrated the fact that the present levees are not high enough to be safe and new grade lines have been established.

Additional Work Necessary

The work that is necessary in order to protect and reclaim these lands may be divided into two general classes:

1. Enlargement of levees and construction of additional levees, with flood gates at St. John Bayou.

2. Drainage ditches and pumping plants to dispose of the surplus rain water falling upon these lands:

A. To collect the waters from all the lands above back-water overflow and conduct them through a high-level ditch to the Mississippi River.

B. To conduct to St. John Bayou, through a low-level diversion ditch, the balance of the waters that would flow out at James Bayou and at Lee-Rowe ditch, so as to permit of the closing of these outlets, and thus lower the head of the back water.

C. Collection ditches on the lands below overflow and a pumping plant to take care of the surplus rain water during periods of overflow in the Mississippi River, or when the flood gates must be closed.

With the undeveloped condition of the low lands, it was deemed inadvisable to attempt the construction of pumping plants, and detailed estimates were not made to cover this and the necessary collecting ditches. It is possible to carry the drainage through the Sikeston Ridge and into the Little River valley and thence to an outlet through St. Francis River, thus saving the permanent expense of the operation and maintenance of pumping plants. But the [illegible] in the way of such a solution at this time are [illegible]. However, without pumping plants, but with flood gates in the levee at the mouth of St. John Bayou (which would be required to exclude the flood waters from the Mississippi) [illegible] large portions of these low lands, especially when the rainfall is light, would receive material benefit, and thus would [illegible] for considerable portions even with heavy rainfall.

For all of the above work except item (C), the estimated cost is approximately $[illegible]. There is [illegible], however, that the U. S. Government will aid (as it has in the past) in the construction of the levees, so that the direct expense to the land will not be so great.

After a careful consideration of the general project by many of the large landowners it was deemed best not to attempt the construction of the high-level ditch at this time, but to go ahead with the low-level diversion ditch and the extension of the levee system (Fig. 1). This will give the greatest benefit for the least expenditure in the shortest time, and will permit the development of much additional land which later on would be in a better position to bear a portion of the larger burden.

The question then arose as to the possibility of a portion of the whole work being able to serve the purpose for the time being, without adding something to it that would be thrown away later. Regarding the levee work there could be no difference; but it was necessary to investigate carefully the situation on account of the low-level diversion ditch being required to take care of the additional surface water which it is planned to carry (eventually) through to the river in the high-level ditch. Near the head of the low-level ditch is located what has been termed the "Ten-Mile Pond basin"; this is composed of several ponds that are joined together and embraces an area of approximately 6800 acres, and can be utilized for temporary storage, without causing injury to any good land, while the ditch is operating to carry the water through to St. John Bayou.

Runoff and Hydraulic Conditions

Drainage districts designed in this territory for $1\frac{1}{2}$-in. runoff have never had overflow troubles, and the capacity of the sandy soil to absorb rain water is very great. It was decided that it would be sufficient for areas of over 300 sq.mi. to figure for $\frac{3}{4}$-in. runoff in 24 hr., and $1\frac{1}{4}$ in. for smaller areas; no very small areas having to be considered in the work thus far planned.

Considerable interest centered in the fact that much water flowed in several of the existing ditches during the very dry season of 1913, due to subsurface flow. The head of the system of ditches was investigated without finding any inflow, in fact at a point 10 miles below the head the flow was practically nothing. At different points this subsurface flow was found to be 0.68, 0.37 and 0.26 sec.-ft. per sq.mi. The sandy soil carries much subsurface flow, and the actual construction of ditches collects this flow and carries it to the low-level lands, where it must be taken care of by ditches or by pumping, depending upon the stage in the river.

The levee grade line is placed at about 3 ft. above the high-water marks established at the time of the recent extreme flood, except at the lower end. There an increment of approximately 1 ft. has been added to overcome an assumed increased flood height on account of the leveeing of the basin above, as well as on account of a special levee likely to be constructed on Kentucky Point, just across the river from New Madrid, which will prevent these waters from flowing across a narrow neck at that place.

For the ditch design, Kutter's formula with the factor $n = 0.025$ (except for special cases) has been used; and combining the assumed rate of runoff with the fall as found on the ground, the proper-sized ditch is obtained by the "cut and try" method. As the proposed main ditches do not follow the general direction of the slope of the country (averaging about 1 ft. per mile) they have to be designed with much flatter slopes, particularly the high-level ditch. The elevation of the grade of the bottom is fixed at the upper end by local conditions of drainage; then where it intercepts inflowing ditches at a grade which is more than a few feet below their present bottom grade line, concrete spillways or drops must be provided.

The required height of the levee along the high-level ditch at points some distance from the mouth is a matter of considerable speculation, there being no way that we could find whereby, with the many variable conditions, it

was possible to figure out anything that would be better than a guess. Hence, they were placed at about 4 ft. above the assumed back-water.

In the location of this high-level ditch the same question of back-water height had to be considered in figuring what portions of the territory could be expected to drain by gravity during extreme floods in the Mississippi River. The best that could be done was to work from the actual conditions that took place during the recent flood as to back-water slopes, which slopes, on account of the breaks in the present levee at the time, were necessarily much disturbed.

City Front Levee at New Madrid

Although the city has been overflowed previous to 1912, the flood has never been more than 1 to 3 ft. deep, and has caused very little damage. The overflows of 1912 and 1913 were high enough to flood the city to depths of 5 to 7 ft. and demonstrated the fact that levee protection is absolutely necessary.

Some 15 years ago, the river bank along this entire front was protected with brush and riprap revetment which has prevented further erosion since that time. However, from the experience with similar work at other places, there is no positive assurance that breaks might not occur, and therefore it was deemed entirely inadvisable to try to protect this front with a concrete flood wall and the question of an earth levee was taken up.

At first, it appeared that there was no escape from property and right-of-way damages that would be equal to or greater than the cost of the levee embankment itself. Then consideration was given to the proposition of acquiring through the second block from the river only right-of-way enough for the levee and borrowing material from some point outside the city. Thus the front street, with the residences on either side, would be left without levee protection. To place such a levee in the front blocks would be unsafe.

Finally, it was decided to plan for the use of the front row of blocks, and with a suction dredge, pump in from the river sufficient material to construct a levee having a base about 200 ft. wide with 10-ft. crown and slopes about 1 on 10, first having raised all serviceable buildings so that they will be above the new levee, calculating to get a price per yard that will be enough lower to make up for the greater yardage.

Inverted Siphons

In order that the surface water from that part of St. John Bayou bottom which will be above the proposed high-level ditch or floodway, may be permitted to reach the mouth of the bayou, a large inverted siphon must be placed underneath the floodway. Other siphons must be placed under this floodway to provide gravity drainage for the lands on the east side of the Sikeston Ridge. As more or less silt will be carried during periods of flood, provision must be made for easily cleaning these siphons.

Ditch and Levee Construction Equipment

For the work heretofore built, as well as for that which is now under way in this section of the country, the floating-dipper dredge is used almost universally for the ditching, and teams with scrapers are used for the levees. In levee work the restrictions as to width of berm and depth of borrow pit make machine work more expensive than team work as a rule, but the time is rapidly approaching when some form of drag-line excavator will be in use more generally.

For the different classes of work now contemplated (Fig. 2), and considering all of the special conditions obtaining, we would expect to use the following equipment: (A) low-level ditch; a floating dipper dredge, of about 3½ cu.yd. capacity, or drag-line excavator. (B) High-level ditch; some form of large-sized drag-line excavator, preferably one on each berm. (C) Standard levee; teams and scrapers, drag-line excavator, or steam-shovel and dump cars. (D) Special levee; a floating suction dredge with about a 12-in. pump.

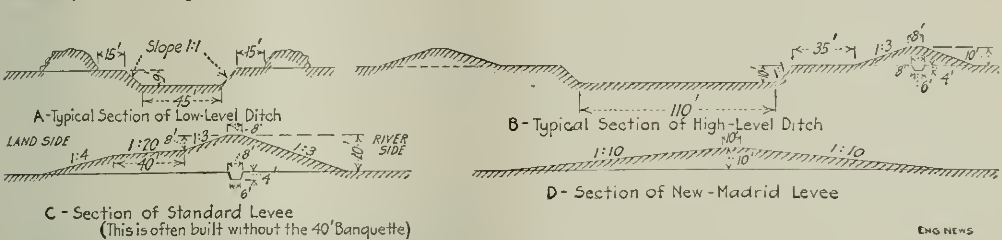

Fig. 2. Proposed Ditch and Levee Cross-Sections

In most of the ditches constructed in this territory considerable trouble has been experienced on account of the banks sliding, due no doubt in a large measure to the sandy subsoil. One of the best ways of overcoming this trouble is to construct the ditches with flat slopes. The floating-dipper dredge does not prove a satisfactory machine for making such slopes, and allowance is made for this by digging to a greater width of base; calculating that the ditch will still be of sufficient size after the sliding has ceased. Most of this sliding usually takes place within a short time after the ditch is first unwatered, and these slides follow no law, hence the result is not only a very unsightly piece of work, but often an inefficient one.

Although the design calls for slopes of 1 on 1, the writer is convinced that as a rule for this territory when the depth of ditch is more than 6 ft. it would be better not to have the slopes steeper than 1½ to 1 and that it will prove economical in the end to pay the increased first cost for such construction.

In scarcely any other class of work is there as much variation in unit price as in earthwork and to give figures without going fully into general details as to conditions, etc., is largely a matter of speculation. In general for this work we estimate that the prices will fall within the following limits (contractor's profit included);

dredge work, 3½ to 5c. per cu.yd.; drag-line work, 10 to 15c.; suction dredge, 12 to 18c.; team work, 16 to 25c.; steam-shovel work, 25 to 40c. On the suction-dredge work, the equipment cost will be large per unit because the amount of work is small.

Before the entire scheme is completed, the quantities will approximate the following: floating-dredge work (low-land ditch), 970,000 cu.yd.; drag-line work (high-land ditch), 10,500,000 cu.yd.; suction-dredge work, 200,000 yd.; team work (all classes), 6,500,000 cu.yd.

Maintenance Experience with a Bituminous-Top Concrete Automobile Highway

In 1908, a private corporation was formed to build and maintain a motor speedway from the outskirts of the borough of Brooklyn, New York City, through the center of Long Island. The purpose of the road, according to an address by W. K. Vanderbilt, Jr., one of the pro-

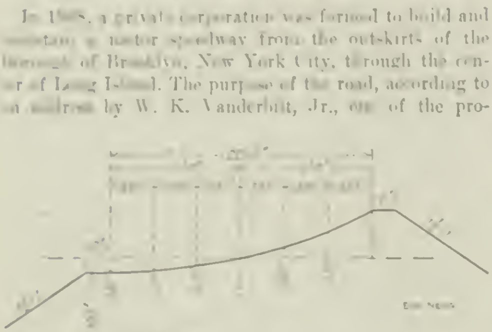

Fig. 1. Cross-Section of Automobile Highway on a 15° Curve

moters, was "to build a highway free from all grade crossings, dust and police surveillance."

A right-of-way 100 to 200 ft. wide and 45 miles long was purchased, and every season since 1908, and including that year, a section of pavement has been laid, the last in 1911. It was originally intended to have a pavement 22 ft. wide, but after the first section was completed the subsequent sections were made only 16 ft. in width.

This road, known as the Long Island Motor Parkway, furnishes an excellent study in road maintenance under special conditions. It is operated as a toll road. Nothing but pleasure motor vehicles and motorcycles are allowed. [illegible] is all supervised by a single individual, so that the road as a whole is an interesting experiment with the particular types of construction adopted. The problem, as is readily seen, is resolved into maintenance against weather and natural conditions, rather than against traffic, so that the opportunity to study this element by itself is unique.

Construction

Subgrade—The road is built for the most part through a naturally well drained sandy loam, such as covers the greater part of Long Island. Much of the route is comparatively level, the principal grades being gentle slopes, although some of the approaches to highway and railway crossings have grades as steep as 8%. In occasional instances, where the natural drainage was poor, tile underdrains were inserted. The earth subgrade was rolled and surfaced to the crown of the finished pavement.

Pavement—Methods of construction varied slightly from year to year. The section of 8½ miles built in the summer of 1908 was a 5-in. reinforced-concrete pavement. No contraction joints were inserted at the time of construction.

Because the glare of the white surface was objectionable, a bituminous material was subsequently sprayed on and sanded, forming a very thin carpet. After the construction of this first section, no reinforcement was used, and a plain concrete base, with bituminous top coat, was constructed, as explained farther on.

The reinforced-concrete pavement was constructed by spreading over the finished subgrade a thin layer of trap rock, 2 in. in greatest dimension. On this layer of crushed stone was spread a wire netting of American Steel & Wire Co., No. 12, 4-in. triangular mesh. Above the wire was spread another thin layer of stone, of 2-in. size; the whole depth of stone not exceeding 5 in. after rolling with a 10-ton steam roller.

The crushed-stone bed was filled with portland cement grout mixed 1:1:1, cement, sand and trap rock, pea size, was poured into the interstices, according to the patented Hassam process. The surface was rolled with a 10-ton roller until no water flushed to the top; the surface was then finished with hand tampers and brushed with rattan brooms. No smoothing or troweling was done, so the surface was left moderately rough and gritty. Shoulders were constructed of earth, compacted by rolling on a 3-ft. strip each side of the pavement. This pavement was guaranteed for five years.

The section built in 1909-'10 was 17½ miles long and

Fig. 2. A 15° Curve Designed for 40 Miles per Hour

was constructed of a 6-in. plain gravel-concrete base with a 1½-in. "Amiesite" top, a patent bituminous process that is included under the general classification, bituminous concrete. The concrete was mixed in the proportion of 1 bag of cement to a cubic yard of gravel. The surface of the concrete was left rough, and stones 1½ to 1 in. in size were set in the soft concrete and left projecting. On this was placed the 1½-in. wearing coat of 2 parts sand and 1 part gravel mixed with bituminous binder, according to the specifications for the Hassam Co.'s "Amiesite." The concrete surface was given a thin coat of bitumen before the wearing coat was spread. The wearing coat itself was spread and rolled like sheet asphalt with a 5-ton roller.

Fig. 3. Mile Straightway, Part of Vanderbilt Cup Race Course in 1908

1 was used; this inverted curved section had the low point 2.67 ft. below the outside shoulder. The particular curve shown in Fig. 1 was one of 14°, or one of 410-ft. radius. It was designed for a speed of 40 miles per hour. Fig. 2 is from a photograph of the same curve.

Subsequent sections built in 1911, '12 and '13 were constructed of a 4-in. gravel-concrete base with a 3/8- to 1/2-in. bituminous wearing coat of the type known as "Hassamite." The coating was sprayed on in two coats under about 300 lb. steam pressure. This pavement is guaranteed for 10 years.

Cross-Sections—The pavement cross-section has an average total crown of about 4 in. or only about 1/2 in. to 1 ft.; in some places the crown appears less. On curves, a superelevation and dished cross-section shown in Fig.

Traffic and Maintenance

Traffic—The traffic, as already noted, is entirely pleasure motor vehicles with pneumatic tires. The largest day's record is 1500 cars, and an average day's traffic is 100 cars. The speed limit is 40 miles per hour, although on straight-way sections, cars ordinarily travel at a much higher speed. In 1908, '09, '10, the Vanderbilt Cup Race course included a part of the parkway, and the speeds approached 100 miles per hour.

Maintenance—There has been but very little repair work necessary. This consisted merely in patching the bituminous top coat and in inserting expansion joints. At the beginning of the spring season a 3-man gang can in three weeks make all nthe necessary patches. The old surface is first swept clean and then a heated bituminous mixture of 2 parts bitumen and 1 part sand is applied, spread with a stub broom and covered with gravel. Rolling is not resorted to. The only other repairs necessary have been in about 60 instances on hot summer days when the pavement expanded sufficiently to bulge. Where this happens, the pavement is cut out and an expansion joint inserted.

Fig. 4. Holes in Bituminous Carpet, 1908 Reinforced-Concrete Pavement

Fig. 5. Typical Transverse Crack

PRESENT CONDITION OF ROAD—The accompanying views were taken the first week in May of this year, before the regular spring patching, and just as the pavement appeared after the winter and during the spring season. Fig. 3 is a view of the one-mile straightaway stretch of road on the reinforced-concrete pavement put down in 1908. This is in excellent condition. The transverse contraction joints and cracks are filled with material from the top coating and the surface is comparatively smooth and noiseless.

In several parts of this section of pavement, places were found like those shown in Fig. 2, where the thin bituminous-wearing coat had broken out. In almost every instance, the concrete surface beneath was very smooth. These holes in the top coat, it appears, are due to water and frost between the concrete base and the bituminous coat, and frequently occur season after season in the same place, owing to the difficulty of making a waterproof patch.

Fig. 5 shows a typical transverse crack, of which there were many. Fig. 6 shows a typical longitudinal crack, of which there were very few. Fig. 7 shows a form of incipient disintegration due to the failure or erosion of the earth shoulder; water apparently has found its way between the concrete and the sub-base; such instances, however, are rare.

Fig. 8 shows an experimental expansion joint installed during the last year; this is the only one of the kind in the road, the others being of a more simple construction as described below. This joint consists of two $\frac{1}{8}$-in. soft-metal plates with a strip of felt between. The concrete has practically broken away from the plates, and the felt works out of the joint, leaving a bad appearing and bad riding break in the road surface. In placing expansion joints at places where the pavement actually heaves in hot summer weather, the regular practice has been to cut away about a 12-in. transverse belt of pavement and insert a $\frac{1}{2}$-in. strip of felt, on each side of which is placed a 6-in. width of tar macadam.

Expansion joints were not used on the original construction, as already noted, but were inserted thereafter by the contractor at such points as required. As the pavements were laid under long-term guarantees, the contractor was allowed to follow his own beliefs regarding the necessity of expansion joints with the proviso that any damage due to expansion would be repaired under the guarantee, and joints inserted where necessary before the expiration of the guarantee period.

The general appearance of the surface of the pavement is that of a tar sidewalk. The surface is rough and gritty and yields a black char which coats the tread of the rubber tires. Fig. 9 illustrates the character of this surface.

As a whole, the pavement has resisted weather conditions for various periods of from one to six years with very fair success; and with the moderate amount of repairing referred to (less than $150 a year for the entire road), and an occasional coat of tar and gravel, the pavement is apparently good for many years, under the traffic it now carries; but its value as an example of this type of construction is, of course, limited by conditions which seldom exist elsewhere. It serves chiefly as an example in differentiating between disintegration due to wear and tear and that due to weather.

The President of the Long Island Motor Parkway is W. K. Vanderbilt, Jr., the Manager is A. J. Kenealy,

The Railway Gage Problem in India

The railways of India aggregate about 18,260 miles of 5½-ft. gage (The Indian standard gage) and 11,750 miles of meter gage, besides some 3000 miles of narrower gages (24-in. and 30-in.). With various railway systems more or less isolated, the break of gage is a serious source of delay and inconvenience, and as there is strong possibility that the railways may have to serve a strategic purpose, the troubles due to break of gage are of military as well as commercial significance. In certain cases a third rail has been laid on standard-gage stretches of line to link together independent meter-gage systems, but this is merely a makeshift. This "battle of the gages" extends over an area of 1,800,000 sq. miles and effects a population of 260,000,000.

The problem of the unification of gage in India has been brought forward again recently by Sir Guilford Molesworth, consulting engineer, in a paper read at a meeting of the East India Association, in London. He pointed out that as far as cost of construction is concerned, there is very little difference. The saving in earthwork is small (not exceeding 3% even in embankments 50 ft. high. The cost of large bridges per mile forms a large proportion of the total cost of the railways, but this cost is affected but slightly by difference in gage. In the case of three large bridges aggregating nearly three miles in length a comparative estimate for the meter and 5½-ft. gages showed a difference of only 3%, the cost of abutments, piers, foundations and river training works being practically the same for both gages.

The narrow-gage movement affected India some 40 years ago, and the meter-gage was adopted for certain lines in 1873 on the sole ground of economy of construction. The actual saving, however, was slight, and at the present time there is practically no difference in cost. One of the principal items of saving on the early lines was in the light track and equipment, but instead of 35-lb. rails and 12½-ton locomotives the meter-gage lines now have 60-lb. rails and 40½-ton engines. Light railways of standard gage can be built as cheaply as those of narrow gage, and can carry ordinary equipment, with the

exception of the heavy mountain locomotives. The question of uniformity of gage is distinct from that of the comparative merits of broad and narrow gage, but Mr. Molesworth considers the 5½-ft. gage the better for transporting the heavy agricultural produce which forms the chief part of the railway traffic in India, besides being the better for the transport of artillery and war material.

As to the military aspect, as long ago as 1873 Lord Roberts made a strong protest against break of gage in the frontier railways, pointing out the inevitable confusion and delay due to the transfer and rehandling of material or troops instead of running military trains through to their destination. This protest led to the abandonment of projects for narrow-gage frontier lines, and to the widening of some 1000 miles of lines that had been built. However, with the present lack of uniformity throughout the country, it is impossible for the railway administration to deal properly with great congestions of traffic, as rolling stock cannot be transferred from one line to another to meet the contingencies which arise in India due to flood, famine, heavy crops, concentration of troops, and other causes.

It is considered that the proper remedy is to convert the meter-gage lines to the 5½-ft. gage, but the mileage to be changed is so extensive that the only practicable course is to adopt a fixed policy for the gradual conversion of the lines as their traffic outgrows their capacity or as opportunity may offer. On some meter-gage lines the limit of capacity has been reached, and the question has arisen whether these should be double-tracked or converted to 5½-ft. gage. It is considered that the latter would give ample increase in capacity, at much less cost, and with the advantage of reducing the difficulties of the gage problem.

The Use of Lime in Water Purification

By Charles P. Hoover* and Russell D. Scott†

SYNOPSIS—The use of lime in water purification is gaining ground. It is already being used at New Orleans, St. Louis, Cincinnati, Columbus, Oberlin, McKeesport, Fargo and many smaller places. Saginaw, Mich., expects to soften its water with lime, and Cleveland is soon going to soften its lake water with lime. Numerous letters from sanitary, municipal and railroad engineers asking for information on lime treatment of water have led the authors to prepare a review of the subject in general and to give special information regarding experience with the lime process at Columbus. Besides the information on Columbus Lime Treatment, this article will deal with lime-treating methods and experience in that city.

The advantages of adding lime to a hard magnesium water, such as is being treated at the Columbus water-softening and purification plant, are as follows:

(1) The water is softened.

(2) Intestinal and pathogenic bacteria are killed and thereby the water is rendered safe hygienically.

(3) The water is purified.

(4) Color is removed.

(5) Lime-softened water is less corrosive to iron pipe, hence no trouble is experienced from the accumulations of "red water" in dead ends of the distribution system.

(6) The sterilizing action of lime prevents bacterial growths.

(7) Nothing is added to the water that was not there originally, as the lime combined with CO_2 present in the water as lime $(CaCO_3)$ calcium carbonate which is insoluble and is removed.

SOFTENING WATER WITH LIME

In order to reduce the temporary hardness of water to the lowest possible figure, lime should be added in quantities just sufficient to absorb the free and half-bound carbon dioxide, and to precipitate the magnesium. If more lime is added than is necessary to absorb the carbon dioxide and to combine with the magnesium, then the water will be overtreated with lime and will have a caustic reaction.

Under ordinary operating conditions, in softening water with lime for municipal purposes, care should be exercised in order to reduce the temporary hardness to the lowest possible figure, and still not have residual or excess lime in the softened water.*

If the alkalinity to phenolphthalein is more than one-half the total alkalinity, too much lime has been added and the water will contain caustic alkalinity; on the other hand, if the phenolphthalein alkalinity is less than one-half of the total alkalinity not enough lime has been added and the water contains bicarbonate alkalinity.

The ideally lime-softened water should contain neither caustic nor bicarbonate alkalinity.

The following table shows in parts per million the relation between alkalinity by phenolphthalein and that by erythrosine or methyl orange in the presence of bicarbonates, normal carbonates and hydrates.

No.	Phenolphthalein alkalinity in parts per million	Total alkalinity by methyl orange, parts per million	Hydrates	Normal carbonates	Bicarbonates
1	44	[illegible]	44	[illegible]	[illegible]
2	44	[illegible]	[illegible]	[illegible]	[illegible]
3	44	[illegible]	[illegible]	44	[illegible]
4	44	[illegible]	[illegible]	[illegible]	[illegible]

Sample No. 1 consists of lime; No. 2 contains too much lime; No. 3 contains exactly the correct amount of lime; No. 4 contains too little lime.

During the past five years the average alkalinity of the Scioto River water at Columbus has been reduced from 155 parts per million to 48 parts per million, and

(2) [illegible] alkalinity by titrating 100 c.c. of the water with N/50 [illegible] as an indicator.

*[illegible]

†[illegible]

the average caustic alkalinity has averaged 1.5 parts per million.

History of Lime Sterilization

Lawrence Experiments—The first detailed study of lime treatment, known to the authors, was made by Allen Hazen at the Lawrence Experiment Station, in 1888. On adding lime to crude sewage he noted a progressive bacterial reduction with increasing quantities. Adding just enough lime to soften the sewage he found a bacterial reduction of 97.9%, and still higher percentage when excess lime was present.

Experiments at Cincinnati—Lime was added to water, with the idea of sterilizing it, at Cincinnati, in 1899 by the Ohio Sanitary Engineering Co., under the supervision of Geo. W. Fuller, who noted a high bacterial reduction in the treated water (94.5%) but attributed it specifically to coagulation rather than to sterilization.

Excess-Lime Method—Dr. A. C. Houston, Chemist of the Metropolitan Water Board, London, England, in the Eighth Research Report of the Metropolitan Water Board, proposed an excess-lime method of sterilizing water. His conclusions were founded on his observations, that quicklime added to raw Thames water in the proportion of 1 part of quicklime to 5000 parts of water, kills B. Coli in 5 to 24 hours and inferentially but certainly, the microbes also of epidemic water-borne diseases, for example the typhoid bacillus.

He proposes purposely to overdose a part of the water with lime, so as to bring about a known bacterial effect, and then after a suitable interval, to mix this portion with enough water, adequately stored or sterilized with ozone or hypochlorite, to neutralize the excess lime. He states in his report that the excess lime is responsible for germicidal action, and that if just enough lime is used to neutralize the bicarbonate alkalinity of the water, no bactericidal action is effected. It is noted in looking over the results of Dr. Houston's work that the excess lime was indicated by the red color produced when phenolphthalein was added to the treated water. The fallacy of this method of measuring excess lime has been stated in a previous paragraph and needs no further comment, but we suggest that this method of chemical technic may have led Dr. Houston to believe that he was using a large excess of lime, when in reality he was measuring the normal carbonates of calcium and magnesium, and not the excess lime.

Experiments at Columbus, Ohio—It has been observed that bacterial tests made for the presence of intestinal bacteria, in the softened water, collected from the outlet of the sedimentation basins at Columbus, Ohio, are negative 92% of the time in 1 c.c. portions. An investigation was made to learn just why the lime-softened water was so free from intestinal bacteria.

The results of bacterial tests made on lime-softened water containing no excess lime at the Columbus water-softening and purification plant, during the past four years, and also the results of numerous laboratory experiments lead us to believe that the action is not necessarily due to the toxic effect of excess lime, but that intestinal bacteria are killed when just enough lime is used to neutralize the free and half-bound carbon dioxide in the water. Bacteria belonging to the colon or typhoid group seem to require carbon dioxide for their develpment.

If two samples of water, one containing CO_2 and the other free from CO_2, be inoculated with typhoid or colon bacilli, these organisms will live in the carbonated water, but will die in water free from CO_2. This was demonstrated in the laboratory of the water-purification plant in several ways:

(1) Samples of well water free from intestinal bacteria but containing free CO_2 were divided into two portions. One portion was boiled until all the CO_2 was expelled and was then carefully cooled to prevent absorption of CO_2 from the atmosphere. The other portion was not boiled. Both portions were inoculated with typhoid and colon bacilli. These organisms lived in the water that had not been boiled, or in any other words, the water that still contained CO_2, but they died out completely in 48 hours time in water that was free from CO_2.

Even supplying the boiled water with oxygen did not render it suitable for sustaining bacterial life.

The results of these experiments tend also to support the contention that excess lime is not the essential factor in producing a water unfavorable to the growth of intestinal bacteria, because in this case lime was not used to absorb the CO_2.

(2) Samples of the softened water collected from the outlet of the sedimentation basins, containing no free and half-bound CO_2, were inoculated with from 5000 to 10,000 intestinal bacteria per c.c. After 24 hours, these samples became free from these organisms. On the other hand these organisms inoculated into the softened water after it had been carbonated with CO_2 lived and sometimes even increased in numbers.

Over 1000 bacterial tests were made on samples of river water, first inoculated with enough crude sewage to introduce from 3000 to 8000 colon bacilli, and from 40,000 to 50,000 total numbers of bacteria, per c.c. These samples, after being inoculated with sewage, were softened with lime. Bacterial analyses were made after 5- and 24-hour intervals. In order to find out whether or not the bacteria were simply dragged down mechanically by the precipitate, or were actually killed, samples of clear supernatant solution were tested, then the samples were vigorously shaken and a second set of tests made.

The results of these tests indicate that lime has a selective action. Intestinal bacteria are destroyed but the reduction of total number of bacteria is not high. Intestinal bacteria are killed and not simply removed by the precipitated carbonates, because the number of intestinal bacteria was no higher in the samples that were shaken than they were in the samples of supernatant liquor. Twenty-four hours contact is not sufficient to insure sterilization of intestinal bacteria, unless the water is overtreated with lime.

Treatment of Sewage Effluents with Lime

Effluents from the sewage-disposal plant at the Ohio Girls Industrial School were treated with lime. The sewage plant at the Girls Industrial School comprises septic tank treatment, sprinkling filters and slow sand filtration.

The raw effluent from the Girl's Industrial School showed the following bacterial analysis:

Quantity of [illegible] tested, c.c.	Gas production in lactose broth. Period of contact, hr. 5	24	48	72
10	+	+	+	+
1	+	+	+	+
[illegible]	+	+	+	+
[illegible]	+	+	+	0

+ = positive reaction. 0 = negative reaction.

Samples were treated with 8.5, 9.3 and 11 grains of lime. The latter proved to be just enough to neutralize the temporary hardness and leave no excessive lime.

The following table shows the bacterial results obtained after the lime treatment:

Period of contact: 5 hr., 24 hr., 48 hr., 72 hr.

Grains per gal. of lime added: 8.5 9.3 11 0 8.5 9.3 11 0 8.5 9.3 11 0 8.5 9.3 11 0

Gas production in lactose [illegible]	+	+	+	+	+	+	+	+	0	0	0	[illegible]
[illegible]	[illegible]	+	+	+	+	0	+	+	0	0	0	[illegible]
[illegible]	+	+	+	0	0	0	0	0	0	0	0	[illegible]
1 [illegible] c.c.	+	+	+	0	0	0	0	0	0	0	0	0

+ = Positive reaction. 0 = Negative reaction.

The results show that excess lime is not necessary, provided sufficient period of contact is allowed.

The results of additional experiments on sewage effluents show that the disinfecting action is not complete when large amounts of organic matter are present.

Conclusions as to Water Disinfection by Lime

Many other laboratory experiments were made and the results of these experiments, as well as results of analyses of samples collected at different points in the plant, seem to indicate the following conclusions:

(1) When enough lime is added to water to absorb the free and half-bound carbonic acid, and to precipitate the magnesium, the bacteria of the colon and typhoid group are killed in 48 hours after being so treated, provided the water does not contain large quantities of organic matter.

(2) The germicidal action is effective in from 5 to 24 hours when an excess of $\frac{1}{2}$ to 1 grain per gal. is added beyond that needed to reduce the temporary hardness to the lowest possible figure.

(3) Intestinal organisms will not live in water containing no free and half-bound carbonic acid.

(4) Lime-softened water inoculated with typhoid organisms or with crude sewage soon becomes free from them.

(5) The action is selective in that certain harmless bacteria grow, but the disease-producing germs do not.

(6) Turbid water can be successfully disinfected by softening with lime and then allowing the turbidity to settle out, along with the precipitated carbonates. Turbid water has never been successfully disinfected with hypochlorite, because the bacteria imbedded in the suspended matter are not destroyed.

(7) The sterilizing action persists indefinitely. In a paper on water disinfection by chemical methods, Samuel [illegible] states the advantages of using chemicals that persist in their disinfecting action, in the following words:

[illegible]

[illegible]

[illegible] 3 grains excess lime would prove to be a very satisfactory and safe water for bathing purposes.

The advantage of caustic water over water sterilized with hypochlorite is that the disinfecting action of the caustic persists, and if the water should become contaminated with pathogenic organisms they will soon become attenuated, and finally die, because there is no carbonic acid in the water, and carbonic acid seems to be essential for their development; whereas a water sterilized by hypochlorite might be satisfactory at the time of being pumped into the pool, but as soon as all the hypochlorite has become dissociated, the chemical offers no resistance to the development of disease-producing organisms that might be introduced into the water by the bathers.

Sterilization of Water Mains

During the floods at Columbus, in March, 1913, it was necessary to stop pumping for a period of 24 hours on account of a section of 36-in. pipe being washed out by the flood water. The distribution system was drained, and the local health authorities advised the people to boil the water, fearing that the mains would become contaminated with surface water. Knowing from our experiments that B. Coli, B. typhosus, B. paratyphosus, and intestinal bacteria will not live long in caustic water, the method of treatment, after pumping was resumed, was as follows:

The water at the plant was treated with enough lime to neutralize the temporary hardness of the water and, in addition, enough to introduce from 1 to 2 grains caustic alkalinity. Samples of the water were collected from all parts of the city, and 24 hours after, the water taken from all parts of the distribution system, showed, by the chemical tests, the presence of excess lime or caustic alkalinity, the water was found to be bacterially pure. This treatment is safe, it does not introduce any taste into the water, and there is no evidence, except by chemical tests, to indicate the presence of causticity in the water.

Better Coagulation Is Effected by Lime Treatment

Lime reacts with the magnesium compounds present in the raw water to form magnesium hydroxide, a bulky, gelatinous precipitate which coagulates the suspended clay particles or mud as readily as the precipitates formed by sulphates of alumina or iron. During the period of the year when the river water is extremely muddy, lime is added to water at the entrance of the mixing tanks in quantities sufficient to introduce excess lime, and better coagulation is affected than when just enough lime is added to neutralize the temporary hardness. This is due to two factors: (1) Magnesium hydrate ($Mg(OH)_2$) is precipitated in the presence of free lime ($Ca(OH)_2$), and (2), in the presence of hydroxyl ions, the negatively charged clay particles are repelled and set in motion by the negative OH ions. They strike against each other and are held together by mutual attraction,[1] forming masses sufficiently large to settle readily. The causticity is neutralized by adding a small amount of alum to the settled water just before it goes to the filters.

The advantages resulting from this method of treatment are: Causticity kills intestinal bacteria, while [illegible]

[1] "The Action of Hydroxyl Ions on Kaolin Suspensions," P. Rohland. B. Chem. Ind. Kolloide II, 192-5.

other bacteria and mud are dragged down mechanically, thus leaving less for the filters to remove; consequently, the filter runs are lengthened and less wash water is used.

The average turbidity of river water treated at the Columbus water-purifications works, for the years 1910, 1911 and 1912, was 63 parts per million. After being treated with lime, soda-ash and alum, the water was allowed to settle for about 12 or 15 hours, and the average turbidity of the settled water was less than 5 parts per million. From June 1, 1912, to Jan. 1, 1913, the turbidity averaged less than 1 part per million, the settled water being so clear that the filters were kept in service on several occasions for a period of seven days without being washed. Even then they did not then show a negative loss of head. During the summer months, when the raw water shows a high average hardness, 250 to 300 parts per million, and low turbidity, the clarification is almost perfect.

Removal of Color

Sperry[2], Chemist in Charge of the Grand Rapids water-purification plant, found that the lime which is used for softening the water also succeeds, through the removal of magnesium, in reducing the color of water to a point as low as that which could be secured at much greater expense by the application of sulphate of alumina. Two or three grains of alum were required to reduce the color from an average of 32 parts per million to an average of 10 parts per million, whereas by using enough lime to neutralize the temporary hardness, and then using enough alum (¼ grain per gal.) to drag down the fine particles of the precipitated calcium carbonate, the color was reduced to 10 parts per million, and the hardness from an average of 188 parts per million to less than 100 parts per million.

Thus both hardness and color were reduced according to Sperry's[3] figures, at a lower cost than would be required for treatment with sulphate of alumina to secure equal decoloration.

The color at Columbus by the combined use of lime, soda and alum has been reduced from an average (covering a period of five years) of 30 parts per million to an average of less than 7 parts per million.

Lime-Softened Water Not Corrosive

Lime-softened water is not corrosive to iron pipes, and since the Columbus water-supply has been softened no trouble has been experienced from accumulations of "red water" in dead ends of the distribution system.

Carbonic-acid gas has a corrosive action on iron pipe, and when this gas is neutralized by the addition of lime to the water, it loses its corrosive property.

Very soft water, containing carbonic acid, attacks lead pipe, and such waters are sometimes treated with lime to make it noncorrosive to lead[4].

Final Step in Softening Process

Following the addition of lime or soda to a hard water, two treatments are essential: (1) The water and the added chemicals must be well mixed by agitation in stirring tanks or baffled mixing tanks to get the reactions well under way; (2) the treated water must be given as much time as possible for further softening reactions to take place and for the precipitates to settle. While a large percentage of hardness is thus removed, there are two means by which a further removal of hardness may be obtained:

(1) Addition of alum. Theoretically, 1 grain of alum should remove 8½ parts alkalinity and increase the sulphate hardness by the same amount. Using this amount at Columbus it is found in practice that at times as much as 30 parts per million of carbonate hardness will be removed, and the sulphate hardness increased from 0 to 6 parts per million. During the periods when the river water is hard, alum is regularly added to the settled water in amounts ranging from ¼ to 1 grain per gal. to secure this reduction in alkalinity. The explanation seems to be as follows: Part of the magnesium present in the raw water combines with the lime to form magnesium hydroxide, which is insoluble and is deposited in the settling basins. The remainder combines with the lime and soda to form a basic carbonate of magnesium, which does not precipitate but remains in a colloidal state. On the addition of alum this colloidal magnesium is coagulated and retained on the filter sand. (2) Passage through sand filters. The residual hardness of lime-softened water may be considerably lowered in this manner. The 30-in. sand layer in the Columbus filters removes about 20% of the hardness of the applied (settled) water, when the river water is at a maximum hardness, and it was found, working on a small scale, that a bed of sand 6 ft. deep would remove as much as 40% of hardness from the applied water.

This seems to be a manifestation of the phenomenon of adsorption, or increased concentration at a boundary surface. All substances of large surface magnitude possess this property of removal of compounds from solution without any chemical reaction taking place. Among such substances are: Charcoal, fuller's earth, cloth, and various colloidal substances, such as gelatin, albumin, starch, and finally aluminum hydroxide. It is probable that the removal of hardness by alum is a process both of coagulation and adsorption.

As a result of application of alum and of passage through sand filters, the hardness of the filtered water has averaged only 89.6% of that of the settled water. Of the hardness removed, three-fourths was in the form of carbonates and one-fourth in the form of sulphates.

A recent analysis of the scale deposit from the sand showed the following results:

	Per Cent.
Loss on ignition	43.00
SiO_2	2.48
Fe_2O_3 and Al_2O_3	2.21
CaO	46.24
MgO	6.24
	100.17
Organic matter	0.88
Ca., calculated to $CaCO_3$	82.6
Mg calculated to $Mg(OH)_2$	9.0

Although the accumulation of scale on the sand grains is troublesome (as will be explained in a following paragraph) it is advisable to remove this material from the water before pumping it into the distribution system, because if it were not removed by the filters, it would very probably be deposited on the walls of the distribution system and in the meters.

[2]Paper read before the 1912 meeting of the American Public Health Association.

[3]Paper read before the Colorado Springs meeting of the American Public Health Association.

[4]See paper read by Geo. C. Whipple before the New England Water-Works Association, Mar. 12, 1913.

At St. Louis, according to Monfort[1], trouble from incrustation in pipes and deposits of scale in meters, was encountered when unfiltered lime-softened water was pumped through the distribution system.

Sections of pipe have been recently cut from Columbus mains laid in 1908, the year the softening operation began, and no incrustation is noted.

No trouble with the meters has been encountered except in those meters containing galvanized parts. A white slimy deposit of zinc carbonate formed in these meters, which clogged them and interfered with the rotation of the disks.

TROUBLES ENCOUNTERED IN FILTERING LIME-SOFTENED WATER

As previously stated, the sand in the filter beds at Columbus is composed practically of two parts scale and one part sand. The sand has become so badly coated that the effective size has increased from 0.415 mm. to 0.62 mm.

The worst feature of this incrustation is due to the fact that the sand grains, after becoming coated, have a tendency to cement themselves together and form hard lumps. These lumps become as large as bushel baskets and are so hard that they have to be dug out of the bed in order to break them up.

It is necessary to shovel the sand from one filter bed to another about twice a year. This takes a force of five men about two weeks' time.

This lumping of the sand is, of course, very objectionable, as it prevents the wash water from breaking through the sand bed uniformly, and it causes the rate of filtration to be high in parts of the bed. Still the quality of the effluent is not materially affected, because the water is always sparkling clear and the bacteria, as has been explained, are eliminated by the action of the lime.

Hints for Preparing Layout Plans for Bridges on Curve

By C. M. Luther*

SYNOPSIS—Factors of a bridge on curve which require preliminary determination are tilt of girders, location of axis, shape of bridge seats, angle between ends and axis, etc. The engineer must fix these matters before design can proceed. Various actual cases show their bearing on the design.

While the stress-analysis of railway bridges on curves has received adequate attention in technical literature, the preparation of layout plans for such bridges has been neglected. The results of this neglect are often painfully apparent. Therefore, a brief discussion of layouts of bridges on curves, and especially the relation of plate-girders to masonry, may be of some interest.

The eccentricity of the center line of track with respect to the axis of the bridge is an important factor in obtaining the distance between centers of the girders, and has a direct bearing on the design of the masonry. It is generally conceded that for all practical purposes the right bisector of the middle ordinate of the span may be taken as the trace of the central plane between girders on the plane of the ties. In other words, this bisector is considered to be the axis of the bridge, or the center line between girders, at the elevation of base of (lower) rail.

The simplest case of a bridge on curve is that of a single-span deck plate-girder bridge on simple curve. If the curve is quite flat, and the span short, so that the middle ordinate for the span does not exceed 1½ in., the chord of the span may be considered as the axis of the bridge at the plane of the ties; otherwise, the above-stated method should be used. Fig. 1 shows the general layout of a bridge on a 5° curve, in which the middle ordinate for the span is over 13 in. The length of the girders is 100 ft. out to out, and the clear length between the ballast walls 100 ft. 8 in., there being 4 in. between the end of the steel and the face of masonry at each abutment. The distance from the base of (lower) rail to the bridge seat is 12 ft. 2 in. In single-span

*[illegible] Engineer, [illegible] Mann & Co., Ltd., Toronto, Ont.

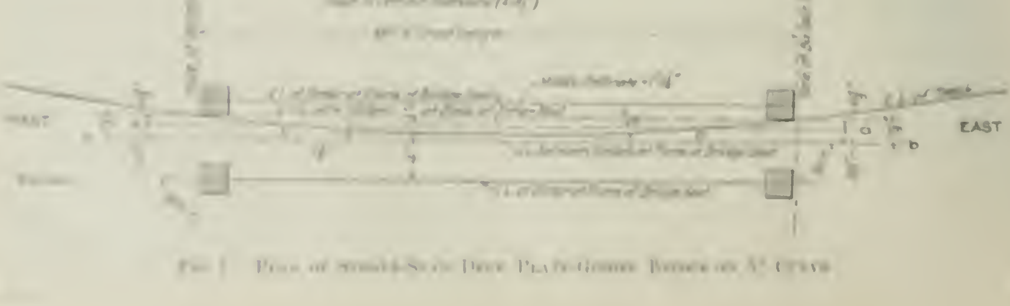

Fig. 1. Plan of Single-Span Deck Plate-Girder Bridge on 5° Curve

bridges, where the crossing itself is not skewed, it is undoubtedly the best practice to have the ballast walls at right angles to the line *a-a* (Fig. 1), and hence to the center lines of the girders. This insures girders of equal length.

The sketch shows two lines designated as center line between girders, *a-a* at the elevation of the base of (lower) rail, and *b-b* at the plane of the bridge seat. It is evident that when the girders are tilted (with an inclination to the vertical equal to the slope of the ties), the offset from the center line of track to the central plane between girders, *at the ends of the span,* will increase with the depth of the girders, attaining the maximum at the plane of the bridge seat, while the central plane between girders will, at the elevation of the bridge seat, approach the curve between points *P-P* (Fig. 1); and as a matter of fact, where the depth of the girders permits, it will even pass outside the curve, as is the case in Fig. 1. The importance of stating clearly, on the layout diagram, the position or elevation at which the center line between girders is taken, cannot be emphasized too strongly.

Therefore, after the center line of track is projected on the bridge seat, the center line between girders at that elevation must be located with respect to the center line of track. This being done, the correct position of the masonry plates and bolt holes on the bridge seat can readily be marked.

Fig. 2 is a section of the girders of Fig. 1, at the bridge seat of the west abutment. The total superelevation of the outer rail is $4\frac{1}{4}$ in., which corresponds to a train velocity of 36 mi.p.h. This superelevation gives the ties a slope of practically 1 : 14. In this bridge, the girders are inclined to the vertical with the same slope, so that the plane of the girder web is perpendicular to the plane of the ties; this eliminates the extra notching of the ties, and insures even bearing for them on the top flange.

In the abutments for this bridge, the bridge seat is made level, which leaves the entire slope of 1 : 14 to the shoes. The ballast walls, of course, following the ties, will also have a slope of 1 : 14. The abutment obviously is not symmetrical about the center line between girders.

In bridges requiring only a very flat slope of ties, the bridge seat of the abutment or pier may be made parallel to the plane of the ties. In that case the masonry members under both girders will be of equal depth.

Fig. 3 is the section of a half-through plate-girder bridge, at the end of the span. It is on a 5° curve; the girders are 63 ft. long and are spaced 15 ft. c. to c. The slope of the plane of the base of rail is 1 in 16, which very nearly gives a superelevation of $3\frac{3}{4}$ in. This slope is distributed between the bridge seat and the underside of the ties, the former taking two-thirds of the total slope and the latter one-third. This arrangement, in this bridge, is due to the Canadian Allis-Chalmers, Ltd. (formerly Canada Foundry Co., Ltd.). If the superelevation were small, the bridge seat could have been made level, leaving the entire slope to the ties, which would have been dapped to the required bevel over the stringers.

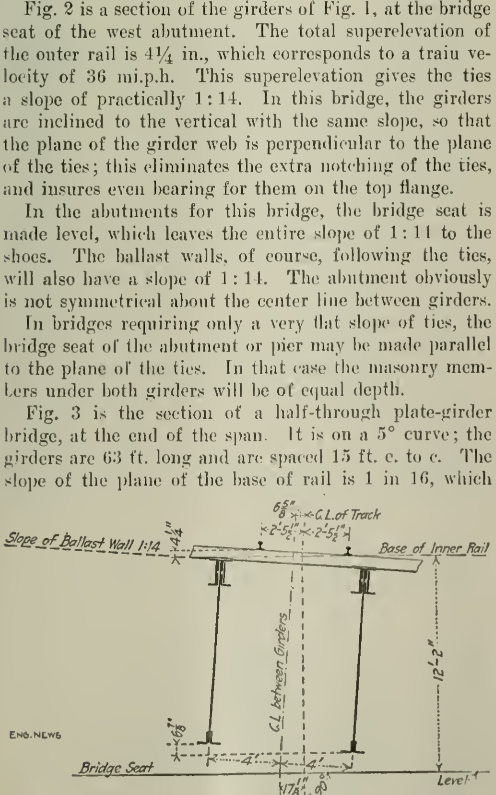

Fig. 2. Cross-Section, Deck Girder Bridge on Curve

It will be noticed that in Fig. 3 the stringers are located symmetrically with respect to the center line between girders. But theoretically the axis of the stringers is eccentric with respect to the axis of the bridge. While for short spans and flat curves, it is permissible to have the axis of the stringers coincide with that of the bridge, it is advisable for sharp curves and long spans (particularly in trusses, in which the floorbeams are spaced farther apart) to consider the panel length between the floor-beams as individual spans with respect to the stringers, and provide for the necessary offset.

In multiple-span bridges on curves, it is a good practice to have the faces of the ballast walls and the center lines of the piers normal to the curve, as shown in Fig. 4. They must be located clearly in reference to a definite line, say to the tangent at one end of the bridge. In

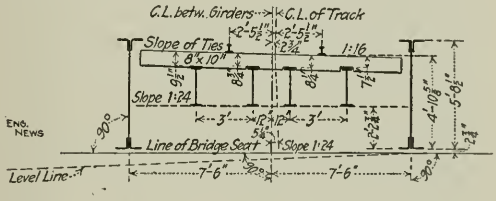

Fig. 3. Cross-Section of Half-Through Bridge on 5° Curve

(Two-thirds of slope in bridge seat, one-third in notching of ties.)

this layout, there will be two sets of girders, the inner and outer girders. The excess of the theoretical length of the outer girder over that of the inner may be expressed by the formula $E = 2\,H \tan \frac{1}{2}\,I$, where E is the excess, H the distance center to center of girders, and I the central angle of the span.

When the curve is rather flat, and the number of the spans comparatively few (three or four), the faces of the ballast walls and the center lines of the piers may all be made perpendicular to the long chord of the bridge. In that case, all the girders will be of same length theoretically, and the piers and abutments will be parallel to each other. But the angle between the center line of girder and the center line of pier will be different for each span, which is an obvious disadvantage.

In very few cases, where a bridge on curve crosses a street, a railroad, a canal, and other similar traffic channels, all at the same place, it becomes necessary to have all the piers parallel to each other and form an oblique angle with the long chord of the bridge. But this layout, for bridges on sharp curves and having more than five or six spans, should be avoided whenever possible, as it means a sharper angle of skew and longer piers at one end of the bridge, and the whole structure will have an unsightly appearance.

FIG. 4. LAYOUT DIAGRAM FOR MULTIPLE-SPAN DECK PLATE-GIRDER BRIDGE ON 6° SIMPLE CURVE

In steel viaducts, on curves, the transverse center lines of the pedestals should be at right angles to the chord of the tower span, i.e., the central plane between bents should be normal to the curve. With this arrangement, it is easier to have the base of the tower nearer the true rectangle, and, if the pedestals have the same elevation on top and the bents the same batter, there will be no skew connections in the framework of the tower. To have the transverse center lines of the pedestals normal to the curve must be condemned. Fig. 5 is the layout diagram of part of a viaduct on a 4° curve.

When a bridge is on transition curve, the same principles may be practiced in determining the center line between girders. It must be borne in mind, however, that the maximum ordinate will not occur at the middle of the span. When the bridge is on the sharper end of the transition curve, and the span is long, this feature must be taken into consideration, and the position where the maximum ordinate will occur must be located. Fig. 6 is the layout of a deck plate-girder bridge on the spiraled approach of a 6° curve. The easement curve is assumed to be a "cubic spiral." The offsets at the beginning and the end of the span, and at the point where the maximum ordinate will be, have been figured by the aid of the well known formula $x = \frac{d^3}{6RL}$ where x = the offset from the spiral to the initial tangent at the end of the first spiral-chord, d = length of the spiral-chord (10 ft. in Fig. 6), L = total length of the spiral, and R = radius of the circular curve. The offset at any other point, say S ft. from the beginning of the spiral, would be $x\left(\frac{S}{d}\right)^3$.

To find the point of the maximum ordinate to any span on the spiral:

Let

C = chord length of the span;

F = larger offset from one end of the chord to initial tangent;

f = smaller offset from other end of the chord to initial tangent;

l = distance from beginning of spiral to the required point;

Δ' = central angle of the spiral for length l;

Δ = central angle of (total) spiral for length L.

Then $\Delta' = \sin^{-1}\frac{F-f}{C}$. This means, of course, a deflection angle of $\frac{1}{3}\Delta'$ from the beginning of the spiral to the

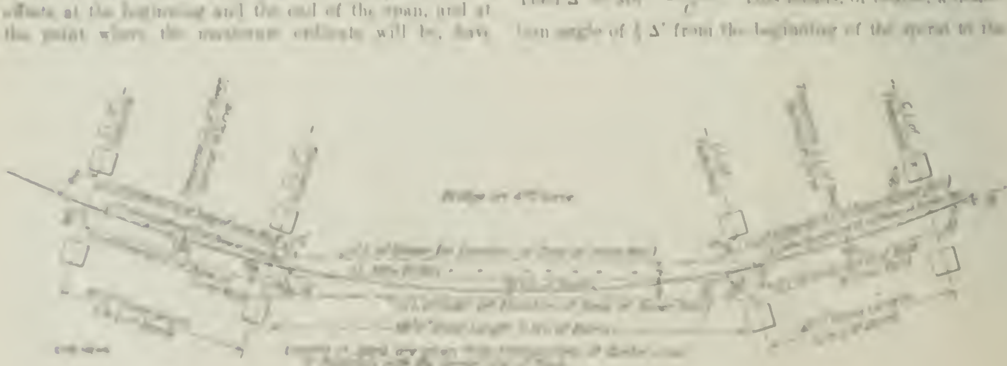

FIG. 5. LAYOUT DIAGRAM FOR VIADUCT ON CURVE

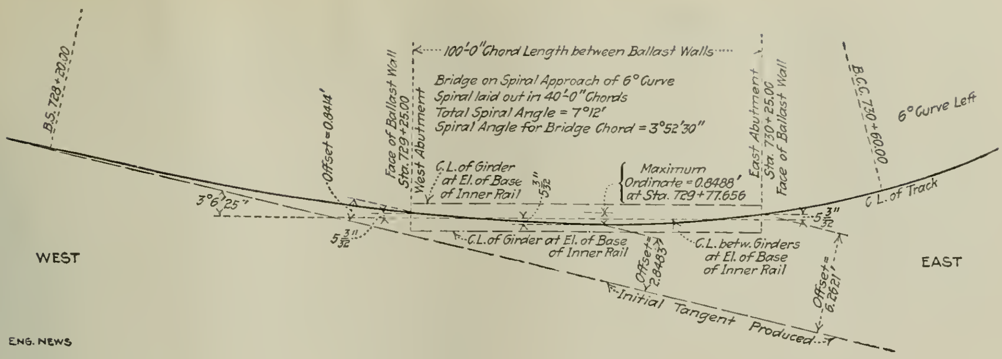

Fig. 6. Single Span on Spiral

required point. With these in hand, the station of the point can readily be computed, and the other elements determined.

Again, since the central angles, for different portions of the spiral, taken from the beginning of the spiral to its end, vary as the squares of the distances, the formula, $l = \sqrt{\frac{\Delta' L^2}{\Delta}}$ will at once give the station of the point required.

Regulations for the Sanitary Protection of the Sources of Water-Supply of Tacoma, Wash.

Strict rules for the sanitary protection of water-supplies drawn from surface sources are becoming more and more common. As an example from the far West we reprint the following from an ordinance of the city of Tacoma, Wash., passed April 2, 1913, which applies to the entire area of Green River above the water-works intake dam:

Sect. 1. The following sanitary regulations are hereby established to be observed by the inhabitants of the watershed of Green River, in King County, being all the areas of land draining into the lakes, rivers, springs, streams, creeks and tributaries flowing and emptying into said Green River above the dam constructed in Sect. 18, township 21 north, range 8 east, to wit:

(1) Every employer of labor, head of a family, hotel-keeper and lodging-house keeper within said watershed shall forthwith, upon ascertaining that any person on his premises is ill from any disease, notify the chief of the Green River police thereof.

(2) Each physician who shall attend a patient afflicted with a contagious or infectious disease within said watershed, shall forthwith notify the health officer of the city of Tacoma thereof; if no physician shall be attendant, the head of the family or other person having the care of the patient so afflicted, shall give the notice above provided for.

(3) The health officer and Green River police shall enforce all reasonable quarantine rules necessary to prevent the spread of any such contagious or infectious disease, and their orders in such respects shall have the same force and effect as similar quarantine regulations in the city of Tacoma.

(4) Every person suffering from typhoid fever, or other water-borne disease, within said watershed, shall be removed to a hospital in the city of Tacoma and there treated free of expense to such persons: Provided, That where such person has been contributing hospital dues to his employer, and is entitled to hospital treatment therefor, his removal and treatment shall be at the expense of the fund thus provided.

(5) No person shall cast into the flowing waters of said watershed, any garbage, manure, excreta, decayed vegetable or animal matter, or other rubbish; nor upon the ground within 500 ft. of the same; but all said material shall be burned up or else removed to the distance above prescribed.

(6) No person shall wade or bathe in any of the flowing waters of said watershed, or permit any animal to stand or wallow therein.

(7) All toilets and privies within said watershed shall be equipped with water-tight receptacles of proper size and permanent construction, and be so arranged as to enable them to be easily emptied or pumped out. Any such toilet or privy not so equipped may be condemned by the chief of the Green River police, and the defect shall thereupon be remedied by the owner or occupant of the premises within five days. When any such toilet or privy requires to be emptied or pumped out, the work shall be done under the supervision of the Green River police and to the satisfaction of the chief.

(8) Every employer of labor shall provide portable sanitary toilets and require the use of the same by employees doing work at a distance from their permanent camps or dwellings, and at any place within 1000 ft. of Green River or any of the lakes, springs or streams tributary thereto.

(9) No trespasser upon land not his own within said watershed shall camp or hunt upon such lands or fish in the waters of Green River or of any lake or stream tributary thereto, where they run or lie within such land.

(10) No unauthorized person shall remove or destroy any notice or sign posted in said watershed by the health officer of the city of Tacoma, or by his order in aid of preventing the pollution of the waters of said Green River.

The penalty for the violation of the ordinance is a fine of not more than $100 or a county jail term not exceeding 30 days, or both a fine and imprisonment.

The Garbage Collection and Disposal system for Chicago, as recommended by the City Waste Commission, was reviewed in our issue of April 9. The recommendations were adopted by the City Council in June, and appropriations were passed to provide for a technical staff to develop, install and commence the operation of the system, and to provide for the necessary plant. The plant already provided for includes the following: A reduction plant and incineration plant adjacent to the present reduction plant on the Chicago river at 39th St., $35,000; two incinerator plants at Goose Island and at Austin and Claremont Aves., $50,000 and $37,000; combined reduction and incineration plant (for unseparated garbage) at 95th St. and Stony Island Ave., $100,000.

The Commission recommended the disposal of garbage at a central reduction plant; the use of ashes and non-combustible waste for filling low ground; and the disposal of combustible waste at small incineration plants, one at the loading station of each of the 14 collection districts. An exception to this was a combined reduction and incineration plant at 95th St. (noted above) to serve two southern districts. The separation to be done by householders, metal and glassware to be recovered by sorting waste at the loading stations, and all the work of collection, transportation and disposal to be done by the city. Dr. Willis O. Nance (Alderman) is Chairman of the Chicago City Waste Commission.

Water Softening at Port Tampa

By Hiram McElroy*

The problem of good water for drinking and domestic purposes has been one of great difficulty in Port Tampa, Fla., ever since its first settlement.

During the early eighties, the Plant System, now known as the "Atlantic Coast Line Railway," built its road thru this territory and established its terminals at Port Tampa, where an abundance of deep water prevailed. Many thousands of dollars were expended from time to time in an attempt to secure water for boiler purposes, drilling no less than 25 artesian wells. An abundance

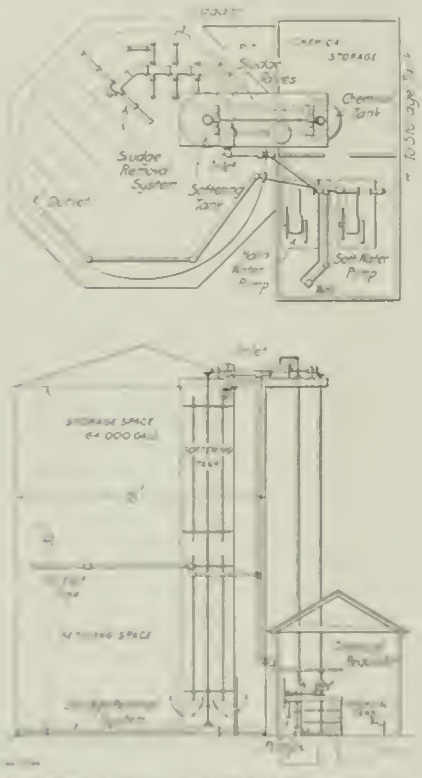

Fig. 1. General Design of Water-Softening Plant, Port Tampa, Fla.

of sulphur water was easily obtained at a depth of 60 to 80 ft., but the quality was so unsatisfactory that its use in boilers or for other purposes was prohibitive. The entire country about Port Tampa and several small lakes across Old Tampa Bay were fully investigated but with no apparent success. In the meantime, water had to be transported by tank cars from the upper parts of the state for the use of engines and shops and to supply the great ocean steamers.

At the time of the Spanish-American War, with 35,000 troops to handle through Port Tampa, together with thousands of horses to be loaded for the campaign against Santiago, the problem of securing even drinking water was perhaps the most serious menace facing the United States Government. A considerable portion of the sickness prevailing among our troops was doubtless due to this cause.

During 1910, the City of Port Tampa erected a municipal water-works plant for domestic and other uses. This plant has been very largely a failure, due to the very hard and ill smelling sulphur water. The citizens had very generally abandoned its use and resorted to the erection of tanks to be filled by rain water from the roofs of the houses, affording an excellent breeding place for mosquitoes. About the only use for the water plant was as a protection against fire.

In view of this condition, it became apparent to the city council that if the plant was to be commercially successful, a softer water must be furnished to its patrons. In March of the present year, the city council retained the writer as consulting engineer to investigate and report on what could be done to improve the city water-supply. The result of the investigation was a recommendation that a water-softening and purifying plant be installed in accordance with plans and specifications submitted. A contract was entered into with R. L. Davis, of Tampa, Fla., for the erection of such a plant, to be equipped with water-softening machinery furnished by the L. M. Booth Co., of New York.

The softening plant was put into operation in June of this year. Its construction is very simple and the plant may be said to operate automatically. No additional labor is required, the regular pumpmen doing the entire work.

Fig. 1 shows the general design and Fig. 2 is a general view of the plant as constructed. The plant has a capacity of 10,000 gal. per hr. of softened water and was installed complete at a cost of approximately $7000, including a storage capacity of 100,000 gal. of softened water. All equipment of the old plant was utilized.

Details of Operation

The water which is to be purified is taken from a 6-in. well 90 ft. deep, located in the pumphouse. It is delivered to the inlet box on the top of the softener by a gasoline engine and pump. The well pump, in addition to supplying the hard water to the softener, furnishes also the power to drive the agitators, an extension of the flywheel shaft serving as the driving pulley.

The chemical solution required to treat the raw water meets the water in the top of the softening tank. This is equipped with mechanical agitators and has a volume corresponding to from 15 min. to [illegible] min. flow when the plant is operated at full capacity of 10,000 gal. per hr. The reason that the period of reaction in the softening tank can be variable, although the plant is run at the given rate of flow, is because the storage space above the outlet pipe contains varying quantities of water due to the widely fluctuating demands. Above the outlet, there is storage for 64,000 gal. of softened water. This is available for instant use even though no raw water at the time is being pumped into the softener. It is, of course, the intention to maintain the tank nearly full at all times.

The function of the softening tank is to thoroughly mix the chemicals with the down-flowing water to insure that there will be no waste or loss of purifying chemicals. The mechanical agitation is an additional benefit in that it coagulates the precipitated impurities so that these will

*Civil Engineer, Port Tampa, Fla., with offices in Tampa, Fla.

quickly settle out as soon as the quiet of the settling space is reached.

The rate of upflow from the bottom of the softening tank to the outlet in the settling space of this softener is 2.85 ft. per hr. This is sufficiently slow to effect a thorough clarification.

Suction for the soft-water pump is taken through the outlet pipe, 17 ft. above the foundation, which is at the bottom of the storage space. The soft-water pump delivers the softened water into a 60,000-gal. elevated steel tank mounted on a steel tower 125 ft. high, from which it is distributed to the city mains.

All of the work of attendance, except lubricating the shaft bearings on the top of the softener, is done at the ground level. The chemical tank (Fig. 3) is located in the chemical storage room of the pump house, so that it takes only a few minutes for the attendant to prepare the day's supply of chemicals. The proportional feeding of the chemical solution is controlled by a Booth automatic chemical-feed regulator.

The sludge-removal equipment consists of two sets of tile-pipe systems, each of which terminates in an 8-in. quick-opening gate valve. The sludge removal draws the precipitated impurities through 77 one and one-eighth-in. openings distributed over the bottom of the settling space. By the use of this system, the sludge is blown off each day. Only a small quantity of water, just enough to convey the precipitate, is used.

The chemicals used to soften the water are 2½ lb. of hydrated lime and 2.25 lb. of 58% soda ash, costing 3c. per 1000 gal.

The accompanying table shows the analysis of the water both before and after softening:

ANALYSIS OF WATER BEFORE AND AFTER SOFTENING, PORT TAMPA, FLA.

(Grains per U. S. gal.)

	Before	After
Calcium carbonate	16.62	0.31
Calcium sulphate	0.35	....
Calcium chloride	13.10	....
Calcium hydroxide	....	0.78
Magnesium chloride	4.78	....
Magnesium hydroxide	....	0.24
Iron oxide, Alumina	0.33	0.12
Silica	1.66	0.93
Suspended matter	0.25	....
Incrusting solids	37.09	2.38
Sodium carbonate	....	2.15
Sodium sulphate	....	0.38
Sodium chloride	28.63	48.30
Nonincrusting solids	28.63	50.83
Free carbon dioxide	0.66	....
Half-bound carbon dioxide	7.31	....
Volatile matter	7.97	....

FIG. 2. GENERAL VIEW OF PORT TAMPA WATER-SOFTENING PLANT

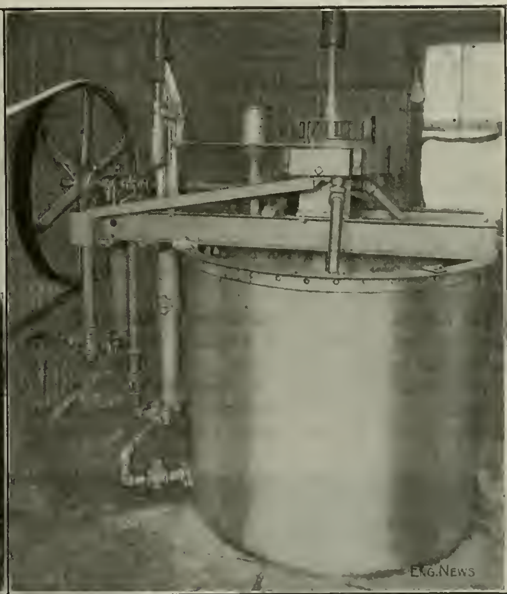

FIG. 3. CHEMICAL REGULATOR AND TANK, PORT TAMPA WATER-SOFTENING PLANT

The use of the softened water by many of the citizens of Port Tampa demonstrates beyond all question that the water softener is not only performing its function of rendering the water fit for domestic and laundry uses but has entirely removed the offensive odor and taste of the water. Instead of being compelled to put up with a vile, ill-smelling and bad-tasting sulphur water, the city is now supplied with a clear, sparkling liquid, free from its former objectionable minerals and bacteria.

Steel Passenger Cars for Indian railways are said to be under consideration by some of the railway companies, owing to the increasing price of teak wood and the decreasing price of steel. At present, steel freight cars are used extensively, and the modern passenger cars have steel underframes with wood bodies. In view of the intense and continued heat, special means of insulation and ventilation would be required for steel bodies of passenger cars.

1000-HP. Steam-Turbine Pumping Units in Charlottenburg, Germany

There are three 1000-hp. steam-turbines driving centrifugal pumps, in the Berlitzhof stations of the Charlottenburg Water Works, which are of interest for comparison with recent American practice. (These units were described in more detail in some notes on turbine construction for water-works service by B. Rosenfeld in "Fördertechnik," November, 1913, and in the "A. E. G. Journal," December, 1913.)

The first two machines were erected in Station 2; each has a surface condenser and auxiliary turbine to drive the air and cooling-water pumps. In the third machine, a water-works type of surface condenser was used—all the water pumped flowing through. This eliminated the cooling-water pump and allowed the air and condensate pump to be driven from the main turbine—which gave the advantage of higher economy to the auxiliaries. The air ejector is direct connected to the turbine shaft and is on the same bedplate with main pump and turbine. The condensate pump, below the condenser drain is on a vertical shaft driven by the main shaft through bevel gears.

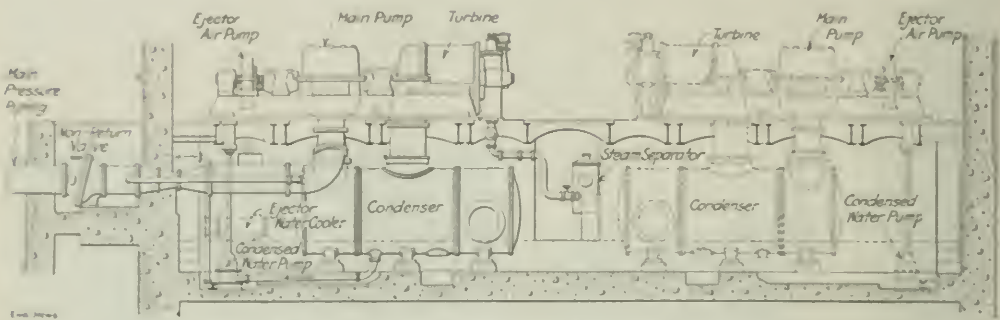

FIG. 1. ELEVATION OF BERLITZHOF PUMPING UNIT

The water enters the condenser (placed immediately below the unit) from the front and is taken out at the back up to the main-pump section inlet. In starting, the pump is primed by a steam injector. The machine can be started from the upper floor as the only machinery in the basement requiring care is the geared condensate pump and this needs no special attention in starting. The vacuum is increased as the turbine advances to normal speed. Only some three to five minutes is required for starting.

The pump has a capacity of 10,550 gal. per min. (15.2 million gal. per 24 hr.) at lifts of [illegible] to [illegible] ft. The guaranteed duty for this capacity varied from [illegible] million foot-pounds per 1000 lb. steam ([illegible] lb. gage pressure and [illegible]° F.) to [illegible] according to the lift. The acceptance tests were made at [illegible]-ft. head and the [illegible] when the guaranteed figure was exceeded by some [illegible]

Solid British Water Tank Engineering: 1793--1914

The recent demolition of the old water tank of the Manhattan Co., New York City (Eng. News, July 23, 1914) should not be passed by without noting that cast-iron water tanks are not only in common use in England today, but are still being constructed; at least they were only a few years ago and it seems fair to infer from a current advertisement that they still are. At the risk of embarassing American manufacturers of steel tanks by foreign competition from cast-iron tank makers, we reproduce with space reduction the following advertisement from the "Engineering Supplement" of the London *Times*.

CAST
IRON
TANKS.

LARGEST MAKERS IN

CONTRACTORS TO THE
ADMIRALTY, WAR OFFICE,
AND CROWN AGENTS.

NEWTON, CHAMBERS & CO., LTD.
THORNCLIFFE IRONWORKS NEAR SHEFFIELD

ESTABLISHED 1793.

It will be noted that the ironworks named was established in 1793. We have assumed in the heading to this note that it has been making cast-iron water tanks for a century. It would probably be equally safe to assume that it will continue the practice for another hundred years—and that the tanks will defy the elements for that length of time.

Why cast-iron water tanks, like pipe of the same material, were not widely introduced from England to the United States would be an interesting but not otherwise profitable subject for discussion. Suffice it to say that before metal water tanks were in great demand here, first wrought iron and then steel plates were readily available, and that where, as was so often the case, long railway hauls to the site and considerable artificial elevation were necessary for the tanks where there were obvious reasons for using lighter material than cast iron. At the same time British ideas of solid and durable engineering construction have led to a continuation of the use of a material and form of water-tank construction which seems in this country to be so much a relic of the past as to warrant the illustrated article on the old tank in New York City to which we referred in our opening paragraph.

We call attention to this contrast in British and American practice in no spirit of criticism, but simply as a matter of passing interest.

Color Decoration for Concrete Bridges

It is not so long since it was apparently a fundamental of bridge design that ugliness is a necessary accompaniment of strength. Happily, that day is gone, and the bridge engineer is now well aware that there is nothing essentially unmanly in accepting some of the architectural concepts of beauty, particularly in the design of concrete bridges, which lend themselves more readily to architectural treatment than steel bridges of more obvious structural composition. At the same time, such artistic treatment has been confined almost solely to disposition of line and mass and has only rarely invaded the field of decoration. Of the use of color decoration, the bridge designer has been especially chary, confining his efforts in that direction to some broad contrasts of mass color, such as the yellow and gray concrete faces of the Connecticut Ave. Bridge at Washington, or to some specially selected aggregate exposed in contrast, as at the Walnut Lane Bridge in Philadelphia.

Of late, there have been a few attempts at radical color decoration by the use of inset tile placed in pleasing line and form on exposed surfaces. One such bridge in which the decoration was on the exposed spandrel wall was built last year at Chicago, and was described in Engineering News some months ago. Another, and more radical example, is the railing of the 66th Ave. bridge at Philadelphia, described on the first page of this issue. The very pleasing effect gained in the Philadelphia bridge is well shown by the views which we print, although the tasteful contrast of color cannot be conveyed by the black and white reproduction. The views are sufficient, however, to demonstrate that, with proper care, and in the proper location, colored tile can be very effectively used to relieve that bareness of line with which concrete is always most economically placed.

The Military Value of Aerial Navigation

The rigid restrictions placed by the military authorities of Europe on the publication of news relative to the events of the war will delay for a long time the gathering of exact information concerning many questions which have hitherto been controverted and which this war is expected to settle.

A whole array of new weapons for attack and defense, by land and by sea, have been developed during the last dozen years and their efficiency is now being tested for the first time. In case a gigantic naval conflict should oc-

our during the war, the question may be settled whether the naval policy of the future will be to continue the building of these so-called superdreadnoughts or still larger and speedier floating fortresses, or whether these great engines of warfare shall be superseded by smaller and speedier ships, of which perhaps ten times as many could be built for an equal expenditure. Until the war is over, however, no detailed account of the behavior of naval vessels in action is likely to be made public.

A certain amount of information, however, is already obtainable bearing on the controverted question as to the value of aerial navigation in warfare. The news is fragmentary and indefinite, it is true, and much allowance must be made for exaggeration. All that has appeared, however, indicate that, as was suggested in these columns years ago, the military value of aerial navigation has been greatly overestimated in the popular mind. Its greatest value by far, without doubt, is for scouting purposes, to obtain information as to the disposition of an enemy's forces. To what extent the aeroplane operators have been successful in obtaining this information under varying conditions of wind and weather is likely for some time to come to remain a military secret with the chiefs of the contending nations.

As for the use of aeroplanes or dirigible balloons for actual attack, by dropping bombs on cities, forts or ships, it does not appear, from all accounts, that anything important in the way of actual destruction has yet been accomplished in this way. A certain value must be allowed, of course, to the panic produced by the appearance of a hostile aeroplane or dirigible over a city and the dropping of bombs upon it. On the other hand, the amount of destruction which it is possible to accomplish by this means has been demonstrated to be comparatively insignificant and can have, strictly speaking, no military value. Both aeroplanes and dirigible balloons have to fly at such a great height in order to escape [illegible] from long-range rifles and machine guns that if they drop bombs, it must be done haphazard for the most part and with little chance of hitting a definite object. On the other hand, the navigators of attacking airships have suffered fewer casualties than might have been expected during their flight over hostile cities, since it was soon found that the danger to those in the city from a hail of bullets directed at aeroplanes at a great height was greater than the danger from any bombs which the navigators might drop.

The Loss of German Products

It is only giving credit where credit is justly due to say that there is probably no other nation in the world whose sudden isolation commercially would cause such widespread loss as has been caused by the isolation of Germany. It is appropriate that this should be recorded here because Germany more than any other nation has won its important place industrially, not by reason of the wealth of natural resources or its geographical location, but by the skill and intelligence with which its people have attacked modern technical problems.

While engineers and chemists are generally aware of Germany's leadership in the field of science and technology, the events of the past few weeks have been a great object lesson to the general public. Few have realized the extent to which the whole world has relied upon German scientists, chemists, engineers and manufacturers for the supply of many materials necessary in the arts. Manufacturers in America and in England who were congratulating themselves on their enlarged opportunities for foreign trade in markets where the supply of German goods was cut off have in not a few cases found their own productive operations seriously hampered because they could no longer obtain certain materials from Germany.

As is well known, steel manufacturers were greatly worried to know what they were to do for their supply of ferromanganese. Manufacturers of fertilizers have had to face the possible shutdown of their works through the cutting off of the supply of German potash. In the textile industries, manufacturers suddenly realized that with access to German ports blockaded by warships there was every prospect that the supply of dyes and dyeing materials would be seriously interfered with. In the drug and chemical trade, prices doubled and trebled when it was realized that with further supplies from Germany cut off, the world would have to get along for a time without certain drugs and chemicals which have become well nigh essential both in the pharmacy and in certain industries.

The above list might be greatly extended. It is in fact only a statement of a few of the important staples, in the production of which Germany has been so preeminent that all the rest of the world has relied upon her to furnish them.

Surely, from a broad point of view, the victory which Germany has gained over the nations of the earth by its leadership in the conquest of the most difficult fields of industrial technology actually surpasses as a meritorious achievement any victory which its great military organization may gain by brute force.

It is said that most of these things for which we and other nations have been accustomed to rely upon Germany, could be produced here if necessary. This is true as relates to most of these materials, provided sufficient time were available, but sufficient time in most cases is a very long time. In the fertilizer trade, for example, investigations have been in progress for a number of years looking to the production of potash from natural sources in the United States. But what has been actually accomplished commercially is the merest trifle compared with the demand which must be supplied. To develop plants which will produce the amount of potash required by the fertilizer trade and other consumers in the United States, and at a cost consistent with commercial success, would require not months but years. Farmers and fertilizer manufacturers are anxious to know what they are to do in the meantime.

The same thing holds true of numerous materials in the dye and chemical trades. Physicians and druggists accustomed to use many of the varied products of coal tar, most of which have originated in and are solely produced by Germany, are in a quandary to know what they can do if the source of supply is entirely shut off.

It is of particular interest to note, moreover, that the manufacturers of England, Germany's great commercial rival, and present enemy, are almost as badly hit as those of the United States by the cutting off of the supply of German products. Our English exchanges reveal that while English manufacturers are making large plans for capturing the export trade in many lands which Germany cannot now reach, they find themselves handicapped at every turn by the cutting off of supplies which

they themselves have been accustomed to obtain from Germany.

Fortunately, the war has not yet closed all the avenues by which Germany can send out its product to the world. Through Holland, a neutral nation, shipments from Germany can reach tidewater and be distributed by neutral vessels.

Of course, the drafts on Germany's male population for the army have paralyzed a large part of Germany's industrial activity, but since an underlying motive of the war is the maintenance of the nation's commercial prestige, it cannot be doubted that Germany will use every effort to continue to supply her foreign customers, so long as any channels for the outlet of her exports remain open.

Cutting Down the River and Harbor Appropriations

It is a pity that the pressure of war news in the newspapers has prevented practically any public mention of the splendid fight which has been waged by Senator Burton, of Ohio, to eliminate from the River and Harbor Bill many millions of dollars of appropriations provided for worthless projects. The Federal government finds its income reduced at the rate of $100,000,000 per annum as a result of the European war. Instead of cutting down its expenditures, however, to correspond to this reduced income, it proposes to make up the deficit by laying additional taxes upon the public, and this at a time when taxpayers the country over are likewise feeling the effects of the war in reduced earnings and increased cost cost of living.

There are government expenditures which can hardly be cut down, but many of the items in the pending River and Harbor Appropriation Bill, as Senator Burton well showed in his keen analysis before the Senate, are as absolute a waste of money as if the gold were taken and thrown into the sea.

Of course, these items are defended on the plea that the expenditure of money by the government makes business for contractors engaged on government work and for firms who furnish their supplies and for the labor which they employ. This, however, is far from being a valid defense for the government expenditure; for if the government left this money in the hands of the taxpayers instead of collecting to spend on rivers and harbors, the taxpayers themselves would lay it out in the employment of labor, so that no more labor is employed in the one case than in the other.

It is now proposed to provide the additional revenue which the government requires, to the amount of $65,000,000, by collecting a tax of 3% on every freight bill paid. This, it is estimated, would yield in a year $65,000,000, or just about what the government proposes to spend next year on river and harbor improvements bill. Nothing could be clearer than the fact that if the railways were allowed to charge this 3% additional increased rates there would be in the railway treasuries during the year $65,000,000 more money available for works of permanent improvement. The contractors and their workmen would be employed on railway work instead of on waterways. As to the comparative public benefit of spending $65,000,000 on railway improvements and the same amount on river and harbor projects of the class condemned by Senator Burton, there could hardly be two opinions in the mind of well informed engineers.

The essential difficulty with the River and Harbor Bill, of course, and one which Congressmen themselves frankly recognize, is that it is in large part a "pork barrel" bill. A member of Congress or a senator is chiefly concerned to obtain a Federal appropriation to be expended among his constituents. Whether the expenditure is to serve any useful purpose or not appears to be a matter of small concern.

There are, of course, a certain number of meritorious and beneficial works for the improvement of navigation which the government properly carries on; but in order that the appropriations for these works may be passed it has come to be the custom to load up the River and Harbor Bill with appropriations for all sorts of absurd enterprises which yield no public benefit and are only planned to secure the votes of the Congressmen in whose district the money is to be spent.

Senator Burton chose a fortunate time for his campaign against this criminal waste, when the attention of the whole nation is directed toward the necessity of economy in all expenditures, public and private. His searching criticisms had such an effect that the Senate committee in charge of the River and Harbor Bill at the close of last week undertook a drastic revision of the measure, and it is reported as likely that some $20,000,000 of the appropriations carried will be eliminated before the bill is again presented to the Senate.

The Necessities of the Railways

The railways' presidents' appeal to the President of the United States last week has attracted wide public attention, as well it might in view of the figures which they presented. In the year which ended on June 30, the gross earnings of the railways of the United States decreased $44,000,000, and their expenses and taxes increased $76,000,0000. Their net income available for paying the interest on their debts, and their notes and other obligations falling due, purchase of new rolling stock and for making improvements, was therefore $120,000,000 less than in the preceding year. With railway finances at this low ebb, the war in Europe paralyzes the financial machinery of the world and makes a further enormous reduction in the volume of traffic and earnings, while shutting off any chance of reducing expenses by lowering wages because of the horizontal increase in the cost of living.

Besides all this, the railways in the territory west of Chicago have had to consent, at the request of the President of the United States, to an arbitration with their employees which will probably result in a further large increase in their expenditures. The railway financial situation is further aggravated by the fact that during the next year bonds and notes will come due, aggregating over $520,000,000.

Facing these conditions the railways appeal through the President to the public asking first of all that no further financial burdens be laid upon them; surely a reasonable request, and second, that in view of the above described situation, the public should recognize the absolute necessity that the railways shall secure additional revenue and that no obstacles should be placed by governmental agencies or other influences, in the way of measures to provide such revenue.

The reasonableness of this appeal is obvious. In fact, had not such an appeal been made by the railway presidents, it is entirely conceivable that it would have been the duty of President Wilson, himself, or of the Interstate Commerce Commission, to make such an appeal, for the railway business is a public business and not a private business, in any sense of the term. It is just as much a public business as if the railways were actually owned by the Federal Government and operated by Federal officials.

The firm or company which is engaged in manufacturing or in mining, or in buying and selling goods, may find business unprofitable, be unable to meet its debts, and be forced to suspend business entirely, as indeed thousands of private concerns doubtless will be by the strenuous times through which we are passing.

But the railway cannot suspend its operations; it is a public necessity that it should continue to run its trains and carry freight and passengers and mails. It must, in the long run, earn enough money not only to pay its employees and those who supply it with materials, but to pay the interest on its debts and a sufficient return besides to those who have invested their money in it, such that it will be able to obtain additional capital for the improvements that are all the time necessary for its efficient operation.

There can be no doubt whatever that one of the great factors in the remarkable success of Germany during the first month of the war, was the wonderful efficiency of the German railway system in the prompt transportation of the vast number of troops and their supplies. It is recognized in Europe that the railway system of a country is just as important a part of its military defense as its regiments of artillery or cavalry. And it is just as true that the efficiency of a country's railway system is a vital element in its commercial prosperity. It is not merely for the railway's welfare, but for the entire country's welfare that the railways of the United States shall be maintained in the highest state of efficiency, and this can only be done if their solvency can be preserved by provision of sufficient revenue to meet their necessities.

Letters to the Editor

The Meadi Sun Power Plant

Sir—I am glad to see the notice which you gave the Meadi sun-power plant on p. 1029 of your issue of May 7. You have been careful enough (which is more than many of the technical press have been) to point out that the engine end of the plant was in a poor state. It was terrible, the steam valves leaked, the piston probably leaked, and the slip of the irrigation pump varied from 10% to 35% according to speed and length of stroke, so it is wholly misleading and unscientific to give the overall efficiency without the careful explanation given in my paper. It would have been more "kind" on my part if I had said nothing (even unofficially as I did) about the overall efficiency, but I thought it more straightforward and scientific to state the facts and then to add some further facts which put the matter in its true light—all as a record of results really obtained. That is, I combined the actual steam production results obtained from the Meadi (Egypt) absorber with the actual steam consumption results obtained from the engine test in London, both sets of tests being made by me. This being done, it is shown that the best hour's run of August 22, 1913, would give [illegible] B.hp. for an acre of [illegible] to the absorber. This is equal to [illegible] B.hp. per acre, while the average power for the five hours' run on that day was [illegible] B.hp. per acre.

When enterprising people have spent some $[illegible] in experimental work, it is a good policy to give an accurate account of the stage to which they have carried their work, even if it be not a completed work, for it encourages others to go on with such efforts [illegible] the dissemination [illegible]. In fact they should be given full credit for their enterprise, for where would engineering be if there were no such "brave spirits"?

A. S. E. Ackermann.

25 Victoria St., Westminster, London.

Instruction in Highway Engineering

Sir—Prof. Agg's outline, in your issue of Aug. 20, of collegiate work which he considers desirable in the education of highway engineers, is most excellent; and what he says in regard to ethical standards puts the truth in words which cannot be misunderstood and should have great weight.

On the other hand, it seems to the writer, as a chemist, that Prof. Agg misunderstands the role that the laboratory plays in highway engineering when he says:

> sufficient knowledge and experience has been gained to enable the engineer to determine by suitable tests, with a fair degree of certainty, the value of any material submitted to him.

This, in the light of my experience, is not entirely true and Prof. Agg seems to recognize this fact as he adds:

> In this work (in the laboratory), experience is of the utmost value, but if the routine tests are taught to the student, and he goes into the field of bituminous construction, he will readily learn to correlate the results of tests with the behavior of the materials in service.

He recognizes the fact that experience, that is to say, a service test, is the main criterion by which the value of any material in use in highway construction may be judged. A laboratory examination will provide no such evidence, but, if a material has proved itself of value by service tests, it will be able to determine the characteristics which it possesses to which its success may be attributed. Reasoning by analogy or inference, such data may be used in comparing the proved material with those which are untried and, in this way, some opinion of the value, or lack of it, of the latter may be formed.

For the highway engineer, the field which the laboratory will chiefly fill is in the control or regulation of the character of bituminous materials, the proportions in which they are used and in affording a record for future reference.

It does not seem desirable that the student should be led to believe that the merits of new and untried bitumens can be determined in the laboratory. Valuable inferences can, without doubt, be drawn; but the long-time service test is the only method of reaching a decision.

CLIFFORD RICHARDSON.

New York City, Aug. 27, 1914.

The Concrete Mixing Plant at Elephant Butte Dam

Sir—In the article on the mixing plant at Elephant Butte, published in your issue of Aug. 6, under the head of personnel, it should have been stated that the preliminary plans were based on a general layout prepared by O. L. McIntyre, Assistant Engineer and former Master Mechanic at this place. This plant layout was followed very closely throughout the design. Mr. McIntyre also prepared the preliminary specifications for the crushers, elevators and conveyors. L. C. Hill, then Supervising Engineer, suggested the use of mechanical measuring devices similar to those used before in other places and the operating mechanism followed as a natural consequence owing to the size of the measures required.

The selection of the title of the above article was unfortunate as the real object was to describe the measuring devices and operating machinery in which this plant differs mainly from other plants. The acknowledgments were made with this point in view and since the plant was mentioned as a whole it is no more than right that Mr. McIntyre be given full credit for the general designs with which the writer had no connection.

L. J. CHARLES,
Assistant Engineer, U. S. Reclamation Service.

Elephant Butte, N. M., Sept. 3, 1914.

Engineering Opportunities in South America

Sir—The letter of Cyrus T. Brady, Jr., in ENGINEERING NEWS, of Sept. 3, entitled "Opportunities for Engineers in the Argentine; A Warning," is an opportune and valuable contribution to this subject; but the writer does not agree with Mr. Brady's statements relative to the cost of living in Buenos Aires.

Compared to that in some of our smaller cities, the cost of living in Buenos Aires would be considered high, as it is practically the same as it is in New York City. Owing to the costs of transportation and import duties, imported articles are naturally expensive; but food stuffs raised in the country and commodities manufactured and produced there are just as cheap as they are in the United States. Imported luxuries such as liquors and tobacco, which are subjected to high duties the same as they are in England, are exceedingly costly, although native wines are cheap. Undoubtedly the costs of the various articles cited by Mr. Brady are given in paper currency, which is approximately equivalent to one-half the value of our own money.

Nevertheless, Mr. Brady's letter brings out forcibly many important facts to which all engineers, as well as those contemplating the extension of their business in South America, should give serious consideration.

While a resident in the Argentine Republic, the writer made a very careful study of business conditions and opportunities in that country at a time when the North Americans there constituted a very small minority.

It must be borne in mind that the basic blood of the native people is Spanish and that they retain many of the traits and customs of that Latin race, just as we retain many of those of the English. Especially is this true of their temperament. Many Argentines went to the Paris Exposition and came back imbued with French ideas and French culture and they decided to make Buenos Aires a second Paris.

It is therefore not difficult to understand why so many Argentines have since sent their sons to France to study engineering and why for a long time French engineering practice and methods of construction have been in use in the republic. The style of architecture of the modern buildings and the methods of living among the wealthier classes are decidedly French.

The Germans, with their stubborn aggressiveness and expansive policy, have secured much of the business there and owe much of their success to the fact that they have studied the needs, temperament and customs of the people and have aimed to please.

South America has in the past secured its capital in Europe to finance practically all of its large projects and for this reason the English have large interests there. European nations have placed their capital in that country with the understanding that the necessary materials would be purchased from their people.

It is also true that many articles manufactured in the United States would find a ready market in the Argentine Republic because of their superiority to similar European products, if our people would only do as the Europeans have done, namely; study conditions there and "aim to please," instead of trying to force upon a foreign people our ideas and our customs and inferior goods; as many firms have tried to do in the past.

Because of our growing power and short-sighted business policy toward them, the Argentines have naturally been suspicious of our proposals; but when once these suspicions have been dispelled, and our sincerity demonstrated by a proper handling of their business placed with us, we will find that they are an enlightened, progressive, intelligent, patriotic and responsive people.

Every engineer who goes to the Argentine Republic will find that he must compete with European talent, and practice. He must learn Spanish and be willing to adapt himself to local conditions. He will find that "patience is a virtue," that gold cannot be picked up in the streets and that only gentlemen are tolerated. When the present war is over, many foreign engineers will undoubtedly go to South America because of the chaotic conditions at home so that technical competition is apt to be greater there than it is at present.

To those who seek business in that country, it must be borne in mind that Argentina is at present suffering from excessive land speculation and unsatisfactory crops; and being unable to float loans abroad, if its business is to become healthy, the United States must go to its relief. United States capital must be invested there in the near future, as Europe will need her own capital for her reconstruction after the war or for the war itself if it continues much longer.

E. L. VERVEER.

518 West 111th St., New York City,
Sept. 5, 1914.

Annual Convention of the New England Water Works Association

The well attended thirty-third annual convention of the New England Water Works Association, held at the Copley Plaza Hotel, Boston, Sept. 9 to 11, was a distinct advance on those of several years past. Seven sessions for business and the presentation of papers were held between Wednesday at ten and Friday at twelve. Except for a carefully planned series of doings for the ladies, all entertainment features were held in reserve until Friday afternoon and evening, when there was a boat and train excursion to Nantasket Beach, where dinner was served.

Besides two superintendents' sessions, at which a variety of practical papers were read and discussed, noteworthy features of the program were three committee reports and papers on the Salem fire, electrolysis and laying water mains so as to reduce leakage to a minimum.

The exhibit of water-works appliances made a new high-water mark. All told there were nearly fifty exhibitors, including four water-works departments. For the first time at a water-works convention, so far as we remember, a booth and chairs were provided for each exhibitor. There were four outdoor demonstrations on a working scale, as follows: Cleaning service pipes by a paper plug and a hand pump; gate-valve operation by a motor truck; calking lead joints by a pneumatic hammer driven from a portable air compressor; and cleaning water mains in a Boston street.

Committee Reports

A Standard Meter-Rate Schedule—Through Allen Hazen, Chairman, the Committee on Meter Rates presented a preliminary report, in which it submitted for discussion a standard schedule or form for meter rates. The proposed schedule deals with the basis of meter rates and not with the rates themselves, which should, of course, vary with local conditions. The schedule provides for domestic, intermediate and manufacturing rates, the first and last to determine the second, which would be half way between. Provision is also made for a service charge, made up of three parts: (1) 10% on the average installation cost of the meter and service pipe, or say $2.50 where the city puts in the service and sets a 5/8-in. meter, or $1 where the meter only is supplied by the city; (2) $1 per annum for meter reading, billing, etc.; (3) $2 per annum for water which passes the meter without being recorded. Where local objections to a service charge are sufficiently strong, the committee suggests that the service charge, so outlined, be divided by 60 and the quotient to the nearest cent added to the domestic rate on the first 60,000 gal., thus making a [illegible] rate.

The proposed domestic rate would apply to water consumed up to 300,000 gal. per annum, the intermediate to the consumption between 300,000 and 3,000,000 gal., and the manufacturing to all in excess of 3,000,000 gal.

The report included a summary table of actual meter rates charged by a considerable number of cities, with comparative figures for the rates recommended by the committee; also a number of diagrams.

After a brief and generally favorable discussion of this report it was voted to take up the subject at an early monthly meeting of the Association. Meanwhile printed copies of the report will be sent to members, with an invitation to submit written discussions.

Statistics of Water-Purification Plants—Through Geo. C. Whipple, Chairman, the Committee on Statistics of Water-Purification Plants submitted a preliminary report and expressed the hope of presenting a final report next January. Its studies have been divided as follows: (1) descriptive data; (2) analyses; (3) engineering; (4) financial, and (5) vital statistics. Tentative standard forms for general descriptions of water purification plants and for reporting water analyses in tabular form were presented. Seven tables of analyses are proposed. Three of these tables show for raw water its (1) chemical and microscopical character; (2) its turbidity and color; (3) total bacteria. The last four tables show for the water delivered to the mains its (4) chemical character; (5) turbidity and color; (6) total bacteria; (7) B. coli. All these data are shown as averages for each month and for the year, with number of test days, and with classified variations in turbidity, color and bacteria. For some of the most significant determinations both mean and median results are given. Two printed pages are well utilized to set forth why "percentage removal of bacteria" is unsatisfactory and has been thrown overboard.

Three "grades of control" of filter plants are proposed: (1) analyses of filtered water at daily or more frequent intervals, with the collection of engineering and other operating data by one or more attendants, constantly employed; (2) weekly or monthly analyses by a trained analyst, with simple daily tests by an attendant constantly on duty; (3) irregular and infrequent analyses, with no daily tests by the attendant.

There was no discussion of this report at the convention, but written discussion is invited. The report will be mailed to the members of the Association and will be brought up for oral discussion in the early winter.

Low Stream Yields—A vast amount of labor carried on for several years past was summarized in a report of 70 printed pages presented by F. P. Stearns, Chairman of the Committee on Low Water Yield of Catchment Areas in New England. The committee was appointed early in 1911 to gather data on the low stream flows of 1908-09-10, but as 1911 proved to be even drier and 1912 and 1913 nearly as dry the studies were extended over the later years as well. They were also extended geographically to cover the Croton River, Esopus, Rondout and Schoharie Creeks (New York City water-supply). Thus altogether 22 drainage areas in New England and eastern New York were studied. The report is really a monograph on the subject indicated. Besides rainfall and runoff records for the 22 drainage areas the general subject of stream yields and storage capacities is discussed. Tables of safe yields for the various streams are given. Numerous diagrams are included. The records and deductions are all the more significant because the recent dry period was drier (in New England) than the very dry years, 1879 to 1883, the driest on record so far as runoff is concerned, though rainfall records indicate still drier years before 1850.

In discussing the paper, Allen Hazen referred to the application of the law of probabilities to runoff and storage problems, contained in a paper which he presented earlier this year before the American Society of

Civil Engineers. Mr. Hazen agreed with Mr. Stearns' opinion that probably still drier years will occur as the records are extended, and that the new low records will again be outdone. Past practice has been to assume that dry periods will be repeated. The probabilities are that 19 out of 20 years will follow the past and that one year will be drier still. Mr. Stearns then expressed himself as quite in agreement with these remarks by Mr. Hazen and added that while lower rainfalls than those recorded must be expected the water consumption of a given city is ever increasing.

H. K. Barrows, commenting on the use by the committee of the FitzGerald evaporation studies, remarked that while these studies were excellent when made yet the few similar studies made elsewhere have given different results. He suggested that since evaporation tests are easily made they might well be carried out in various localities governed by different conditions.

Standard Specifications for Cast-Iron Pipe—In behalf of this committee, Frank A. McInnes, Chairman of the committee and President of the Association, stated that several meetings with manufacturers have been held but the committee is not yet ready to submit its final report [which report, it is hoped by many, will lead to a joint standard specification on the part of the New England and American Water Works Associations.—Ed.]

General Papers

Of 14 papers on the program, 12 were presented by the authors in person, and two, which had been printed for circulation at the meeting, were read by title, the authors not being present.

Allowable Leakage from Water Mains—E. G. Bradbury, of Columbus, Ohio, presented some remarkable records of low leakage from new water mains laid under rigid specifications and tested in the open trench before covering at Akron, Ohio. The leakage shown by 86 tests on a total of 16.76 miles of 4- to 30-in. cast-iron mains laid by contract averaged 83.4 gal. daily per inch-mile and on 8.9 miles of 6- to 10-in. pipe (38 tests) 61.7 gal. daily per inch-mile (leakage per mile for each in. diameter of pipe).

Dexter Brackett did not think it practicable to keep trenches open for testing pipe in thickly populated districts. Mr. Bradbury remarked that the length of open trench can be lessened by using more gates and that this will pay where it is necessary. His paper showed that the water saved by tight mains will pay for considerable extra capital outlay. W. C. Hawley said that in open-trench work he had found leadite very useful, because when jointing with that material short lengths of pipe can be tested readily. A. D. Flinn stated that in some special cases lead wool had been used advantageously.

Lessons from the Salem Fire—A unique study of the water-supply of Salem, Mass., during the recent conflagration was contributed by Frank A. McInnes and Clarence Goldsmith, of Boston. Besides summarizing actual fire-engine operations, the authors presented the main results of water-consumption experiments made after the fire, with outlet conditions as nearly as possible like those during the fire. The chief lesson drawn by the authors was that large connections between street mains and fire-sprinkler systems of protected buildings cause a great risk since, as in the Salem fire, falling walls may break these large services, causing so large a loss of water as to cripple the water-supply and fire service.

In remarks supplementing the paper Mr. Goldsmith stated that Boston limits sprinkler connections to a diameter of 4 in., but permits a number of connections of that size, generally 50 ft. apart.

A number of representatives of fire insurance companies made a stand for larger connections than 4 in. One of these speakers urged that the primary cause of the Salem conflagration was an undermanned fire department —27 men, some of whom were off duty. Had not the fire been allowed to get under way the breaks in sprinkler connections which bled the water-supply would not have occurred. Salem also needed much better building construction than it had.

Notwithstanding all that was said by others, the authors of the paper stuck to their opinion that the Salem conflagration was due to breaks in large sprinkler mains and that 4-in. connections would have been sufficient to supply the sprinklers at Salem, and that connections of that size, supplemented by fire engines coupled up through an outside siamese, would suffice and afford greater safety than a larger connection. This opinion seemed to be concurred in by all present except the insurance representatives.

Electrolysis—A review of the electrolysis studies made during the past few years by the United States Bureau of Standards was presented by E. B. Rosa, Chief Physicist of the Bureau. Many of the results have already been made available through various Technological Papers, and further papers are to be published.

So far as tests of pipe coatings have gone, these are of little service in presenting electrolysis. Insulating joints are more useful, but of limited value. Track drainage or pipe drainage must be the chief resort (assuming that a complete return-wire system is not used). There should be more coöperation in the prevention of electrolysis. In any event the burden of protecting underground structures from electrolysis should be borne by the street-railway companies.

Metering an Old City—How Boston is being converted from a practically unmetered to a metered city under mandatory state legislation passed in 1907, but little heeded until 1909, was told by James A. McMurry, Engineer-in-Charge Income Branch, Boston Water-Works. This legislation required that all new services be metered and that old services be metered at the rate of 5% a year. Some 5000 to 6000 meters a year are being set. At first this work was scattered over the city, but soon the practice of metering a whole district at a time was established. This not only saves installation costs but also affords an opportunity to make valuable studies of results obtained. Some 36,000 meters have been set, increasing the percentage of services metered from 6% in 1908 to 11% at the close of 1913. The effect on the consumption of the whole city can be seen and there has, of course, been a much more notable reduction in per capita consumption in the districts fully metered.

Other General Papers—Papers on "The Construction of Dams," by A. E. Walden, of Baltimore, Md., and on the "Miraflores Water Purification Plant," by Geo. M. Wells, of the Canal Zone, were read by title in the absence of the authors.

Papers at the Superintendents' Sessions

Eight papers were read at the two superintendents' sessions. Most of these brought out, as was intended, a goodly discussion.

HOUSE-BOILER TROUBLES.—F. F. Forbes, Brookline, Mass., told how changes from attic tanks to direct supplies for hot-water boilers has added to his worries. There were two boiler explosions in Brookline during the last year. The remedy suggested was expansion tanks. This suggestion seemed to meet with general approval by those who listened to the paper but one speaker urged that in addition to using expansion tanks hot-water plumbing should be inspected to insure good materials and workmanship.

MACHINE CALKING OF LEAD JOINTS.—At Waltham, Mass., as told by Daniel T. Higgins, a truck-mounted air compressor and pneumatic hammer is reducing the time and cost of calking water mains. The outfit cost only a few hundred dollars. It has also been fitted with an air drill, for use in rock trench excavation.

THE CARE OF GATES AND HYDRANTS.—Patrick Gear described how this is done at Holyoke, Mass. Each fire hydrant has a card record and is periodically inspected. In winter a lead is used to sound the hydrant for ice. If ice is found, it is thawed out and if water is found it is pumped out. Salt is used to prevent freezing.

As to gates, Mr. Gear had more to say about their design and material than upon their maintenance. He recommended a liberal use of brass parts where the members are specially liable to wear or corrosion, and that provision be made for cleaning sand from small as well as from large gates.

In the discussion of this paper one member told of the use of a pint to a quart of wood alcohol per hydrant to keep hydrants from freezing and another told of using crude glycerin.

WATER USES DIFFICULT TO CONTROL.—These, as outlined by Wm. F. Sullivan, Nashua, N. H., include water for building purposes, street and sewer flushing. The remedy is universal metering or at least metering all who practice abuses. Several speakers told of tricks to beat the water meter. The only way to prevent these is through sealing of the meter and its connections to prevent tampering.

THE AUTOMOBILE AS AN EFFICIENCY AGENT IN WATER-WORKS MANAGEMENT.—The uses and costs of eight motor vehicles at Worcester, Mass., were set forth by Geo. W. Batchelder of that city. The first automobile was introduced in 1909. Records have been kept for each car. The yearly operating costs range from between $200 and $300 for a Ford car to $1200 to $1300 for general-service cars and a large truck. The latter has been used extensively for hauling pipe and has been highly advantageous for heavy work, long hauls and emergencies.

PUBLIC WATERING STATIONS.—Frank E. Merrill, of Somerville, Mass., told how he had coöperated with the State Department of Animal Industry in efforts to reduce glanders by getting rid of common open horse-watering troughs. In their place, provision is made for filling pails carried by teamsters. A 10-in. cast-iron pipe is set in the ground at the curb line, cut off and set 18 in. above the sidewalk. A 3/4-in. service connection is topped with a cover, equipped with two self-closing faucets and a hose connection for filling pails and with a drinking fountain for human beings. Near the sidewalk a bowl for dogs and birds is placed. The outfit costs about $50 for material and $10 more for labor. Besides the primary object of helping reduce glanders, it is believed that these watering stations will save a considerable amount of water. The speaker exhibited one of the appliances, and referred also to another exhibit at the convention, showing how Boston has converted old common troughs to pail-filling stations.

Mr. Merrill introduced the State Commissioner of Animal Industry and the President of the Massachusetts Society for the Prevention of Cruelty to Animals, each of whom addressed the convention. The former was heartily in favor of, in fact largely responsible for, the widespread abolition of the common horse trough in the Boston Metropolitan District and cited both statistics and leading veterinarians and other authorities in support of his views. The latter opposed the innovation on the ground that lazy drivers would not take the trouble to get off their wagons and fill pails, and that, as a consequence, many horses would have to go for long periods without water, and would then injure themselves by overdrinking. He also cited figures which he thought proved that horse troughs have comparatively little to do with the spread of glanders. In conclusion he sought to clinch his claims by asserting that there are all sorts of germs everywhere—which no one denied.

LOW WATER CONSUMPTION IN MILTON, MASS.—D. A. Heffernan reported that Milton uses only 39 gal. of water per capita per day because (1) it has the universal meter system, extending to all uses of water except through fire hydrants; (2) because it insists on good construction, and (3) because of thorough inspection. The water department lays all service pipe to a point inside the building wall and allows no one except firemen to use fire hydrants.

USE OF THE MAGNETIC DIPPING NEEDLE IN LOCATING SERVICES AND GATE BOXES.—Edward D. Eldredge, of Onset, Mass., stated that in small places it is often necessary to find services after street grades have been changed and where no records have been made. The dipping needle will aid in this task, even through 6 or 7 in. of concrete sidewalk. L. M. Bancroft, of Reading, Mass., said he had located a service box by this means beneath 13 in. of concrete, and J. M. Diven, of Troy, N. Y., went Mr. Bancroft 1 in. better.

Annual Convention of the Roadmasters and Maintenance-of-Way Association

The 32nd annual convention was held at the Auditorium Hotel, Chicago, Sept. 8 to 11, with the President, T. F. Donahoe (B. & O. R.R.) in the chair. The attendance was large, and in connection with the meeting there was an exhibit of track materials, tools and appliances arranged in a hall adjacent to the meeting room. An unusual feature which is peculiar to the meetings of this association is that very few papers or reports are presented, but that these are discussed at such length that they more than suffice to occupy the time of the convention. There were nine sessions, eight of which were devoted mainly to business, and although only five reports were presented, some parts were accepted as information owing to lack of time for full discussion.

PROPER OPERATION OF TRACK TOOLS AND APPLIANCES.—This report, presented by J. W. Hall (N. Y. Central R.R.), opened with an explanation of the increasing use of machinery in track work, owing to its economy as compared with hand labor and to the increased weight and

size of many parts used in track construction. Motor cars in place of hand cars save time and energy of the track men, and enable the same number of men in a gang to do more work or a smaller number of men to do the same amount of work as when equipped with hand cars. Rail-handling machines for loading rails on cars and distributing new rails from cars not only do the work more expeditiously but eliminate the rough handling which may result in damage or fracture of the rails. For rail renewals, there are machines which, with three to six men, do the work otherwise requiring a large gang of men to handle long and heavy rails.

Other uses of machinery are in such heavy work as ditching, the distribution of ballast, and the spreading of filling material; and also in such light work as drilling and cutting rails, boring and dressing ties, driving screw spikes, tamping ballast, etc.

RAIL RENEWALS—This report was presented by A. M. Clough (N. Y. Central R.R.), and was discussed at great length in regard to the various phases of the work. There was considerable discussion as to whether or not ties should be respaced when new rails are laid, and the general opinion was that this is not necessary, while eliminating the work greatly reduces the time consumed. Several railways now leave the ties alone, simply dressing them at the rail seat where necessary, and adjusting them to give proper support at the joints. The report submitted the organization for a rail-renewal force, but some members were inclined to object to this, since no two roads would have the same conditions or use exactly the same force.

ORGANIZATION OF LABOR AND MATERIAL FOR TRACK MAINTENANCE—This report was presented by P. J. McAndrews (Chicago & Northwestern Ry.). It showed the great amount of money expended under the direction of the track department (averaging $10,000 per month per roadmaster), and advocated a system of organization in which the work of all the roadmasters of any one division would be under the supervision of some official who would direct the work of the division as a whole. This would avoid the trouble and expense due to operating separate work trains, rail-renewal gangs, extra gangs, etc., on each roadmaster's district. The report recommended the maximum length of line for the roadmasters or supervisors as follows: 50 miles of double-track, 100 miles of single track with heavy traffic or 125 miles in easy country with light traffic.

Another important recommendation was that track forces should be maintained permanently, throughout the year. At present, every railway cuts its force to a minimum in winter and increases it in the spring, when the supply of efficient men does not equal the sudden demand. This results in loss of time and money due to the continual employment of new and inexperienced men. Much of the work can be done as well in winter as in summer, and the work as a whole would be done better and at lower cost if spread over the year instead of concentrated in a few months, as under the present system. There was general agreement with the suggested system, but it did not appear that any roads have yet introduced it, the economies of track labor not being comprehended as a rule by railway officers.

TRACK ACCESSORIES—This report, which was presented by M. Donahoe (Chicago & Alton Ry.), dealt with a variety of matters, and the first of these were discussed in such detail that the remainder of the report was accepted as information, without discussion. In regard to rail joints, the committee recommended 24-in. angle bars, with four bolts, supplemented by a base or bridge plate where traffic is heavy. For frog guard-rails an 8-ft. length was recommended, but this was struck out, as there was a general opinion that longer rails are preferable, and that it is not desirable to specify the length.

There was considerable discussion as to whether bolts or clamps are the better for securing the guard rail to the track rail, and as to the use of tie-plates and rail braces at guard rails. Cast manganese guard rails were mentioned, but the members present had little experience with these. Other matters covered by the report were switches, frogs, switchstands, tie-plates, rail anchors or anti-creepers, screw spikes and drive spikes, track bolts of nickel-chrome steel, and the narrow-head "frictionless" rail for curves (ENGINEERING NEWS, July 2, 1914).

As to this last, only one member had experience, and he spoke of tests showing that with a train on a heavy grade the speed increased on curves having this rail on the inside, while it decreased on curves laid with ordinary rails. Some members spoke of getting the same result by shifting worn rails from the outer to the inner side of the curve, but it was pointed out that in such case the weight of the wheel comes on the overhanging side of the rail head and not directly over the web, as in the special narrow-head rail. Consequently this shifting of worn rails or curves was hardly desirable for track with heavy traffic and high speeds.

CLEARING AND POLICING RIGHT-OF-WAY—This report was read by J. P. Corcoran (Chicago & Alton Ry.). It dealt with such work as the cutting of weeds and grass, removing old rails and ties, the handling of scrap, maintenance of ditches and fences, and the clearing of yards and station grounds. Trackwalking and bridge inspection were included also. The report recommended the old practice of requiring the trackwalker to do all kinds of miscellaneous work during his trip, but this was objected to in the discussion. It is better for him to be simply an inspector, doing only such work as is essential to the safety of the track. The miscellaneous work of driving loose spikes, repairing fences, etc., can be done to better advantage in periodical trips of the entire section gang.

OFFICERS

Officers for 1914-15 were elected as follows: President, P. J. McAndrews, C. & N. Ry., Belle Plaine, Ia.; Secretary, L. C. Ryan, C. & N. W. Ry., Sterling, Ill. The next meeting will be held at Chicago in September, 1915.

The Annual Convention of the National Paving Brick Manufacturers Association

The chief features of interest to engineers in connection with the 11th annual convention of the National Paving Brick Manufacturers Association, held in Buffalo, N. Y., Sept. 9-11, were the discussion of inspection of paving brick and the excursions to various parts of Buffalo and the surrounding country to visit and inspect brick pavements in all stages of age and construction.

As to the inspection of brick, there appeared to be much dissatisfaction with present practice. The specifications

are constantly becoming more severe, and the manner of testing the brick after they have been distributed on the road to be paved, and there condemned, often works great hardships on both the paving contractor and the brick manufacturer.

Nevertheless there was no unanimous demand or apparently desire on the part of the brick manufacturers for universal factory inspection. The objections seemed to be a horror of having a corps of inspectors about the plant, as might be necessary if each buyer had his own personal inspector, and a frankly expressed fear that there would be subsequent difficulty in disposing of brick condemned by anyone of the inspectors—and it is necessary to dispose of the poorer as well as the best brick in order to run a brick plant at a profit.

Coupled to these objections were, of course, the usual ones that competent inspectors were rare, and differences of opinion as to what constituted good qualities in paving brick. To remedy the former one member proposed the training of engineering graduates at the plants by a few months' course in practical brick making. In regard to tests of paving brick it was generally conceded that the manufacturer is not safe from having his brick rejected unless he makes it test 2% better than that specified by the buyer, in order to provide for uncontrollable variations in the rattler test.

O. N. Townsend, of the T. B. Townsend Brick & Construction Co., Zanesville, Ohio, spoke strongly in favor of factory inspection, which had been tried on a large scale at his plant. He said it was the only means by which he could get a contractor to undertake the pavement of several miles of the Lincoln Highway under the Ohio State Highway Department specifications. So successful and satisfactory had factory inspection proved that he stated his plant would hereafter insist on it for all contracts; if necessary, he would pay the inspector. C. P. Mayer of the C. P. Mayer Brick Co., Bridgeville, Penn., spoke in much the same strain.

The only result of this discussion was an unofficial resolution adopted by the manufacturers at an informal conference with the paving-brick committee of the American Society of Municipal Improvements (E. H. Christ, Grand Rapids, Mich., Chairman) providing that it was the unanimous sense of the meeting that the paving-brick committee of the American Society of Municipal Improvements recommend to its society factory inspection of brick, for [illegible].

The following officers were elected: President, Charles J. Deckman, of the Deckman-Duty Brick Co., Cleveland, Ohio, who has been President since 1911; Vice-President, J. W. Robb, of the Clinton Paving Brick Co., Clinton, Ind.; Treasurer, C. C. Barr, of the Barr Clay Co., Streator, Ill.; Secretary, Will P. Blair, Cleveland, Ohio.

[illegible] of the association and [illegible] will appear in a later issue.

NEWS NOTES

A Water Tank Fell [illegible]

A [illegible] Water Main Burst [illegible]

A Freight Train Went Through a Flood-Weakened Bridge [illegible]

Sept. 1. Two men who are missing are thought to have been killed.

A Wood Bridge Collapsed under the weight of a load of gravel, at [illegible]ersville, N. Y., on Aug. 31, dropping team, wagon, gravel and two men into [illegible] Creek. Local reports state that the structure was weakened by high water resulting from heavy rains. The bridge was built four years ago. It failed when the load was halfway on the structure.

A Train Went Through a Wood Bridge on the Missouri, Kansas & Texas Ry. at [illegible] Creek bridge five miles south of Tyler, Tex., at 5 p.m. Sept. 1. The engine passed over the bridge, and, as far as can be learned from local reports, the oil tender left the track near the south end of the bridge. The baggage, combination and chair cars went through the bridge, which was a 16-bent structure.

Floods in Kansas City, Mo., on Sept. 7, damaged the Country Club district, the South Side along Brush Creek, the East and West Bottoms, Sheffield and other districts. Conditions were most severe in the southwestern part of the city and in Rosedale, a suburb, where the water reached a maximum depth of 25 ft. A 10-hr. rain, with a precipitation of 6.94 in., caused the floods. In addition to many flooded buildings, two railway bridges across Turkey Creek were carried out, and three persons were killed.

The Alaska Government Railway Surveys are reported to be making good progress. The parties in the field number about 110. Work will be suspended during the winter, but it is expected that actual construction can begin as soon as spring opens.

The Chicago Water-Works Intake Tunnel, which is to extend under the lake from Wilson Ave., is to be built by day labor. All bids were rejected and the City Council has granted authority to the Department of Public Works to carry on the work. It will be under the direction of John Ericson, City Engineer.

A High Discount Rate for Payment of Metered-Water Bills in Chicago will go into effect on Nov. 1 as the result of a city ordinance passed on July 2. The discount will be 25% on all meter bills paid within 30 days of the date of the bill. The present discount rate is 1[illegible]. The meter rate is 6[illegible] per 1000 cu. ft. or [illegible] per 1000 gal.

American Trade Opportunities in South America are to be investigated by the American Express Co. Two representatives of the company, Messrs. [illegible] and A. R. Howard, will sail from New York, Oct. 1, to visit the principal cities in Brazil, Uruguay, Argentine, Chili and Peru to investigate methods by which United States trade with South America can be developed.

Beginning of an Industrial-Education System is being attempted in the New York Public Schools. At present two schools in Manhattan, [illegible] in Brooklyn and [illegible] in Queens are being operated on a cooperative plan, which seems for the moment more [illegible] of plant than for definite industrial education. By dividing the school into two groups, or by [illegible] a duplicate school to use the same plant, it is possible to have one group in the classroom while the other is in the shops, library or playground.

The Last Section of the Harlem River Tunnel of the Lexington Ave. subway in New York City was sunk Sept. 1[illegible], 1914. This is the fifth of similar sections which have been successfully sunk to form the subway crossing under the river. Each section consists of a steel box of [illegible] ft. [illegible] ft.) long and wide enough to provide room for a four-track tunnel of [illegible]. This box is floated out over the [illegible] and sunk into a prepared position by filling with water. It is then filled with concrete and [illegible] to the next adjoining section already in place. The work is being done by the Arthur McMullen & Hoff Co.

Fewer Forest Fires on Cape Cod [illegible]

Manufacturers of Motor Vehicles [illegible]

ness. While the purchase of cars for pleasure and as a luxury will doubtless be seriously restricted for some time, the great casualties among horses in the war seem certain to cause a great shortage and still higher prices for horses not only in Europe, but in America. The high prices of grain and forage and the great demand for cattle, which seem certain to prevail for a good while to come, will also tend to discourage the raising of horses, and will make their keeping more expensive. All these things tend to favor the substitution of motor-driven vehicles for horses wherever the conditions permit.

The Proposed Standard Specifications for Steam-Boiler Construction framed by a committee of the American Society of Mechanical Engineers were considered at a public hearing at the Engineering Societies Building in New York City on Wednesday, Sept. 15. The hearing was attended by about 150 engineers representing the principal steam-boiler manufacturers and representatives of state boiler-inspection departments and also various societies interested in steam-boiler construction, inspection and use. John A. Stevens, of Boston, chairman of the committee, presided and opened the meeting with a statement of the causes which had led to the formation of a committee by the Society to frame standard specifications. Addresses were made by E. H. Wells, President of the Babcock & Wilcox Co., and Thomas E. Durbin, of the Erie City Iron Works, which emphasized the absolute necessity to the boiler-manufacturing interests of standard specifications suitable for adoption by all the states of the Union. After further general remarks, the meeting took up the proposed specifications for discussion in detail.

Suggestion for a Cantilever Bridge Across San Francisco Bay is made by C. E. Fowler in "Western Engineering," issue of Sept. 1914, on the basis of general designs which he has worked out. The plan is for a crossing between Telegraph Hill (San Francisco) and Oakland via Goat Island. The span from Telegraph Hill to Goat Island includes three cantilever spans of 2000 ft. with tower spans of 250 ft., and at either end a land span (cantilever arm and terminal suspended span) of 1350 ft. east of Goat Island the bridge would consist of an 880-ft. cantilever span, a mile and a half of viaduht, and about two miles of fill. In general design the structure is closely similar to the Forth Bridge, except that the suspended span is much longer, being 700 ft. The constructive details also show a leaning toward the Forth type. In particular the compression members are double-walled tubes, but instead of being circular as in the Forth bridge they are octagonal, with metal cross-sections up to 3600 sq.in. The cost of the bridge in its entirety is estimated at $75,000,000, of which the three-span cantilever structure between San Francisco and Goat Island is figured at $49,000,000.

A Reinforced-Concrete Building Collapse at La Ceiba, Honduras, on Aug. 19, was reported in a very generally circulated press dispatch as follows:

> Washington, Aug. 20—Forty British and American workmen were killed today in the collapse of the new concrete customs house at Ceiba, Honduras, according to a dispatch to the State Department.
> D. J. Klodt, formerly of San Antonio, Tex., was the only name given of those killed. Many workmen were burned under the ruins and smothered. A fire enveloped the structure after its collapse.

We are informed by H. J. Hill, Chief Engineer Vaccaro Bros. & Co., of La Ceiba, that the cabled report was greatly exaggerated. He states that the second floor of the reinforced-concrete customs house under construction at La Ceiba failed on Aug. 19, and in the collapse four workmen were killed outright, one fatally injured and three more slightly injured. The apparent cause of the collapse was a lean concrete, which failed immediately upon the removal of the falsework. As near as could be determined by Mr. Hill, who had nothing to do with the building, the proportions of the concrete was about one part cement to eight parts sand, with no gravel or broken stone in the mix. The building was designed for the contractor by B. G. Klodt, who was killed in the collapse. There was no inspection other than that of the builder.

Temporary Closing of Drawbridges to accommodate commuting traffic near large cities has been repeatedly urged by commuters, but the historical and apparently inalienable rights of water navigation over land traffic in practically every instance has prevented such closing. Commuters who have suffered from this refusal of the law to recognize modern conditions will appreciate the recent order of the Secretary of War approving amended regulations governing the opening of the draws of the Highway Bridge and the Pennsylvania R.R. bridge over the Potomac River at Washington, D. C., whereby both of those bridges are closed against water traffic between 8:20 and 8:50 a.m. daily, except to vessels employed or controlled by the Government.

It was suggested by the railway interests that the draws be closed from 7 to 9:30 a.m., and from 4 until 6 p.m. daily because of reported frequent delays to land traffic during these hours. Navigation interests, however, made a stout protest against such a long closed period and the War Department permitted only the morning closing. In recommending the closing General B. C. Kingman, Chief of Engineers, said:

> After due consideration of the evidence adduced at the public hearing and the papers in the case, it is thought that the closed periods advocated by those interested in land traffic would result in detriment to river traffic out of all proportion to the benefit to be derived by traffic over the bridges. On the other hand, a closed period of not longer than 30 min. during the morning rush hours appears to be necessary to accord some measure of relief to traffic over the bridges and will not in the opinion of this office impose an unreasonable hardship on water-borne traffic.

PERSONALS

Mr. Chas. W. Gates, Highway Commissioner of Vermont, has been nominated as the candidate for Governor on the Republican ticket.

Mr. S. S. Senter, formerly Engineer of Construction of the Wheeling & Lake Erie R.R., has been appointed Superintendent of Bridges and Buildings, with headquarters at Brewster, Ohio. The office of Engineer of Construction has been abolished.

Mr. Henry A. Woods, M. Can. Soc. C. E., Assistant Chief Engineer of the Grand Trunk Pacific Ry., at Winnipeg, Man., has been appointed Chief Engineer to succeed Mr. B. B. Kelliher, M. Can. Soc. C. E., resigned, as noted in our personal columns of last week.

Mr. Frank W. Skinner, M. Am. Soc. C. E., has resigned as Associate Editor of the "Engineering Record" and will devote his whole time to private practice, specializing in methods and plant for the execution of civil engineering construction, with office at 41 Sherman Ave., Tompkinsville, N. Y.

Mr. Frank F. Fowle, M. Am. Inst. E. E., Consulting Electrical Engineer, has closed his New York City office at 68 Maiden Lane, and has moved to Chicago, Ill., where he has been appointed one of the receivers of the Central Union Telephone Co., with headquarters at 212 West Washington St.

Messrs. Vrooman & Perry, Consulting Engineers of Gloversville and Amsterdam, N. Y., announce the dissolution of the partnership. Mr. Morrell Vrooman, Assoc. M. Am. Soc. C. E., will maintain offices at Gloversville and Amsterdam, and Mr. Charles ~ Perry, Assoc. M. Am. Soc. C. E., will open an office at 102 Hudson Ave., Albany, N. Y.

Mr. W. E. Duckering, recently with the Oregon Short Line Ry., at Pocatello, Idaho, has been appointed Instructor in civil engineering at the University of Washington, Seattle, Wash. He takes the place of Prof. C. W. Harris, who has been granted leave of absence in order to devote his time and attention to the development of some small water powers in the Cascade Mountains.

Messrs. J. Wharton Bartholow and George H. Willits have formed the Bartholow-Willits Engineering Co., of Galveston, Tex., and will engage in the general practice of civil engineering, with headquarters in the Reymershoffer Building. They will specialize in sewage disposal and public utility valuation. Mr. J. C. Nagle, M. Am. Soc. C. E., Chairman of the Board of Water Engineers, State of Texas, is Consulting Engineer of the new firm.

Mr. Frederick C. Noble, M. Am. Soc. C. E., Division Engineer, Public Service Commission, First District, New York, who has been in charge of the East River tunnel division of the new subways in New York City, has resigned. He has been in the city subway work since the first subways were built in 1900. It is understood that he has left the Public Service Commission to devote his whole time to private practice, much unfinished work having been left by his late father, Alfred Noble, Past-President of the American Society of Civil Engineers.

Mr. W. S. Moseley has been promoted to be Mechanical Engineer of the Carolina, Clinchfield & Ohio Ry., with headquarters at Erwin, Tenn. Mr. Moseley was educated at the Virginia Polytechnic Institute. He began railway work as a messenger boy in the auditor's office of the Norfolk & Western Ry. in 1894. From 1902 to 1909 he was a draftsman in the Mechanical Engineer's office, with the exception of two years when he was an instructor at the Institute. He was appointed a draftsman with the Carolina, Clinchfield & Ohio Ry. in 1909.

Mr. William F. Allison, M. Am. Soc. C. E., formerly Professor of [illegible] and sanitary engineering at the University of [illegible], has been appointed Professor of municipal and highway engineering at the University of Washington, Seattle, Wash., succeeding Prof. E. J. McCaustland, M. Am. Soc. C. E., whose resignation was noted in these columns Aug. 2[illegible], 191[illegible]. Prof. Allison is a graduate of South Dakota State College, Purdue University and Cornell University. He served as an Engineer Officer in the U. S. Volunteer Army in the Philippine Islands during the Spanish American War. He was formerly a member of the faculty of the Colorado School of Mines and City Engineer of Golden, Colo.

Prof. Granville R. Jones, Assoc. M. Am. Soc. C. E., Professor of sanitary engineering at the University of Kansas and Engineer of the Kansas State Board of Health, has resigned to accept an appointment as Professor of hydraulics and sanitary and water-supply engineering at the new engineering school of the Johns Hopkins University, Baltimore, Md. Prof. Jones graduated from Ohio State University in 1[illegible] and from the Massachusetts Institute of Technology in 1[illegible]. For two summers he was with the Pennsylvania R.R. in Chicago, Ill., and for a year was with the Mt. Vernon Bridge Co., Mount Vernon, Ohio. For five years following his graduation from the Massachusetts Institute of Technology in 19[illegible] he was employed at the water filtration plant at Washington, D. C.; during the last three years he was Assistant Superintendent. Since 1912 he has been at the University of Kansas.

OBITUARY

Parker Stafford, former Railroad Commissioner of Maine and a civil engineer, died Sept. 7 at his home in Bucksport, Maine. He was born in 1842.

Victor J. Hedden, President and Treasurer of the V. J. Hedden & Sons Co., builders, New York City, died Sept. 11, at his home in East Orange, N. J., aged 68 years.

Wilson Brown, a retired civil engineer and a former member of the engineering staff of the Pennsylvania R.R., died Sept. 11, at his home in Setauket, L. I., aged 63 years.

[illegible] F. Stevens, a retired civil engineer, died at his home in South Orange, N. J., Sept. [illegible]. He was born in 1832 and was a nephew of Edward A. and Robert Stevens, the founders of Stevens Institute of Technology.

[illegible] M. Markley, for many years Supervisor of Bridges and Buildings of the Peoria & Eastern division of the Cleveland, Cincinnati, Chicago & St. Louis Ry., [illegible], Ohio, died Sept. [illegible]. He was 67 years old and had been in the railway service for 42 years.

[illegible] S. Anderson, former General Manager and recently Treasurer of the Granite Ry., which was built and operated to develop the granite quarries of Quincy, Mass. He was born in Massachusetts in 18[illegible] and graduated from Harvard University in 18[illegible]. He was at various times Assistant Treasurer, Secretary and General Purchasing Agent of the Union Pacific Ry.

[illegible] A. [illegible], a prominent mechanical engineer and founder of the [illegible] Engineering Co., Allentown, Penn., died at his home in that city Sept. 1[illegible] [illegible]. He was born [illegible], N. Y., [illegible] years ago. He was a graduate of Stevens Institute of Technology and for several years was employed by the Jackson Manufacturing Co., [illegible].

[illegible] H. [illegible], General Superintendent of the North Works of the [illegible] Steel Co., at Chicago, died on Sept. [illegible]. [illegible]

ENGINEERING SOCIETIES

COMING MEETINGS

ILLUMINATING ENGINEERING SOCIETY.
Sept. 21-2[illegible]. Annual convention in Cleveland, Ohio. Secy., Joseph D. Israel, 29 W. 39th St., New York City.

RAILWAY SIGNAL ASSOCIATION.
Sept. 22-24. Annual convention in Bluff Point, N. Y. Secy., C. C. Rosenberg, Times Building, Bethlehem, Penn.

ATLANTIC DEEPER WATERWAYS ASSOCIATION.
Sept. 22-26. Annual convention at New York. Secy., Addison Burke, Philadelphia, Penn.

INTERNATIONAL IRRIGATION CONGRESS.
Oct. 5-9. At Calgary, Alta. Secy., Andrew Miller, Industrial Commissioner, Calgary.

AMERICAN ELECTRIC RAILWAY ASSOCIATION.
Oct. 12-16. Annual convention at Atlantic City, N. J. Secy., E. B. Burritt, 29 West 39th St., New York City.

NATIONAL COUNCIL FOR INDUSTRIAL SAFETY.
Oct. 13-15. Annual "Safety Congress," at Chicago, Ill. Secy., W. H. Cameron, Continental Bank Building, Chicago.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.
Oct. 20. Convention at Los Angeles, Calif. Secy., C. A. Lichty, 319 North Waller Ave., Chicago, Ill.

INTERNATIONAL ASSOCIATION OF FIRE ENGINEERS.
Oct. 20-23. Annual convention at New Orleans. Secy., James McFall, Roanoke, Va.

AMERICAN ROAD CONGRESS.
Nov. 9-14. Atlanta, Ga. Permanent headquarters, American Highway Association, Colorado Building, Washington, D. C.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.
Oct. 6-9. Annual meeting at Boston, Mass. Secy., Charles Carroll Brown, Indianapolis, Ind.

NATIONAL MUNICIPAL LEAGUE.
Nov. 17-21. Annual meeting at Baltimore, Md. Secy., Clinton Rogers Woodruff, North American Building, Philadelphia, Penn.

AMERICAN PUBLIC HEALTH ASSOCIATION.
Nov. 30-Dec. 5. Annual meeting at Jacksonville, Fla. Secy., Prof. Selskar M. Gunn, Massachusetts Institute of Technology, Boston, Mass.

Association of Iron and Steel Electrical Engineers—The eighth annual meeting of the Association was held in Cleveland, Ohio, Sept. 15. The Secretary is W. T. Snyder, National Tube Co., McKeesport, Penn.

The Cleveland and the Detroit Engineering Societies held a joint inspection trip of Detroit industries on Sept. 12. A banquet was held in the evening. About 150 members of the Cleveland society went to Detroit on the Friday night boat, returning Sunday, Sept. 13.

National Association of Port Authorities—The third annual convention was held in Baltimore, Md., Sept. 8-10, and was well attended by representatives of practically all of the important ports of the country. This association was organized in 191[illegible] to bring together all those who are interested in port financing, management and construction. Necessarily, this is a rather limited field of membership, but in the short time since organization the association has a representation from almost all of the United States ports and by a revision in the constitution this year is expecting to take in the other prominent American ports.

The papers presented were as follows:

"Relation of Federal Government to the City in Port Development," Col. William M. Black, U. S. Army, New York; "The Engineer's Part in Port Development," Francis Lee Stuart, Chief Engineer, B. & O. R.R., Baltimore, Md.; "Baltimore Harbor," [illegible] F. [illegible], President and Engineer of Harbor Board of Baltimore; "Trade Organizations as a Benefit to the Commerce of the Port," Charles J. [illegible], Philadelphia, Penn.; "The Port of Los Angeles," Maj. Robert H. Raymond, [illegible], Los Angeles, Calif.; [illegible] [illegible] Jr., Chief Engineer, New Jersey Harbor Commission; "The Port of Seattle," [illegible] H. M. Chittenden, Seattle, Wash.; "Trend of American Port Construction," William J[illegible] [illegible], Consulting Engineer, New York; [illegible] J. F. Coleman, Consulting Engineer, New Orleans, La.; "The Port of Boston," [illegible], Boston, Mass.; [illegible] Harry C. [illegible], Secretary of [illegible]; [illegible] Department of Commerce, Washington, D. C.

The following officers were elected for the ensuing year: President, [illegible] F. Lackey, President of the Harbor Board of Baltimore; Treasurer, Harry C. [illegible]; Secretary, [illegible]. It was decided to hold next year's meeting at Los Angeles, in the fall of 1915.

REVIEWS AND NOTES

Unique Hydraulic Experiments

REVIEWED BY EMIL KUICHLING*

THE TRANSPORTATION OF DEBRIS BY RUNNING WATER —By Grove Karl Gilbert. Based on Experiments Made with the Assistance of Edward Charles Murphy. Professional Paper 86. Washington, D. C.: U. S. Geological Survey. Paper; 9x12 in.; pp. 259; 92 illustrations.

This interesting publication gives an account of numerous experiments made during the past few years at Berkeley, Calif., for the purpose of ascertaining and studying scientifically the laws that govern the transportation of gravel, sand and other mineral débris by running water. The work was undertaken in connection with the investigation of serious problems caused by the overloading of certain rivers in California with the waste matter of hydraulic mining operations, and its results constitute much-needed additions to our stock of knowledge of physiographic geology and hydraulic engineering.†

Mineral matter is transported by a stream in two ways, the finer particles being held in suspension by the water and the coarser ones moving by sliding, rolling or leaping along the bed of the channel. The suspended material is easily obtained from samples of the flowing water, and much is known as to its quantity; but the amount of heavier matter that travels on the bed cannot be determined in this manner, and little information concerning it is yet available. The primary purpose of the experiments was to learn the laws which control the movement of the bed load, and especially the relation of this load to the stream's slope and discharge and to the size and shape of the material. Four factors were thus introduced besides the velocity of the current, and it is very probable that the width, depth and shape of the channel are additional factors.

Much attention was given to the mode of transportation of the bed material, whether by sliding, rolling or leaping. When the load is small, the bed is molded into ridges or hills, called dunes, which travel downstream, as the current erodes their upstream faces and deposits the material on the downstream faces. With progressive change of conditions tending to increase the load, the ridges or dunes gradually disappear and the channel becomes smooth or even; but with further changes the bed again becomes uneven and a system of dunes will form that appears to travel upstream, owing to erosion on the downstream face and deposition on the upstream face. Both rhythms of débris movement are initiated by rhythm of water movement.

An important distinction is also made between "stream" transportation and "flume" transportation. In the first the load traverses a plastic bed composed of its own material, while in the second, it traverses a rigid bed. "Capacity" and "competence" are also terms used to designate respectively the maximum load of a given kind of material which a given stream can transport, and the ability to start the movement. For example, a stream at its low stage cannot move the débris on its bed, but with increase of discharge the velocity increases until transportation or traction of a certain grade of material begins, and the *discharge* is then said to be competent for that grade; similarly, if the velocity is increased by an increase of slope so as to begin a movement of the bed material, the steeper slope is said to be competent.

The experiments were made mostly in two wooden troughs or channels of rectangular section, 31.5 and 150 ft. long, 1.96 ft. wide and from 1.4 to 2.4 ft. high. The first trough was hinged at its head so as to facilitate changes of slope, while the second was kept horizontal. By means of false bottoms different degrees of channel roughness were secured, and with temporary partitions in the long trough, curved and crooked continuous channels 1 ft. wide were formed. A third trough, 14 ft. long and 0.67 ft. wide, had its woooden sides replaced by plate glass for 3.5 ft. at its middle, and a fourth trough, made of galvanized sheet iron of semi-cylindrical form and 1 ft. wide, was used only in the experiments on flume traction. The results showed that in flumes the transportation of débris in gentle currents is usually by rolling and sliding, and that the capacity of the current increases with the coarseness of the material. In swift currents the principal movement is by leaping, and the capacity increases with the fineness of the grain. The capacity is always increased by increasing the slope and varies on the average with the 1.5 power of the slope; it also varies with the discharge in some irregular ratio.

*Consulting Engineer, 52 Broadway, New York City.

†An abstract of the Professional Paper here reviewed, prepared by the author to preface his volume, was reprinted in "Eng. News" of Sept. 10, 1914, pp. 563 and 564.

An attempt was also made to apply the experimental results to natural streams, but as the flow of a river is a highly complex phenomenon and the transportation of débris by it involves intricate reactions, this work was not accomplished satisfactorily. It was found that the load of transported material is related to the controlling conditions or factors in a very involved manner, and that the law of control for each condition was qualified by all other conditions.

The experience gained from the Berkeley experiments, however, is very useful in carrying out other experiments which may yield more accurate data of the same general class, and it is hoped that the well equipped hydraulic laboratories at Dresden, Karlsruhe and Berlin, where accurate models of river channels are available, will soon be able to furnish observations which will apply more fully to river engineering.

The author has referred to most of the studies of the subject that have been made in our own country and abroad, but cites only the general conclusions reached. The phenomena of subsidence and velocity at which particles of matter settle in still water are discussed very briefly, being regarded only as incidents to transportation, and similarly only a few data are given in regard to the quantity of matter carried in suspension by streams. From lack of reliable observations little information is given about the volume of material that is carried along river beds by traction, although an excellent general discussion of this subject is submitted. In the Yuba River at flood stages, the tractional load is given by the author as being equal to the suspended load; at the mouths of the Mississippi, Humphreys and Abbot estimated that the tractional load was 11% of the suspended load, and in contrast thereto, the elaborate study on the beds of the Rhone by Guerard is cited to show that the tractional load was about three times greater than the suspended load. Such enormous variations in estimates and observations indicate clearly the need of many further studies of rivers. It may also be mentioned in this connection that an extensive compilation of data relating to the suspended and tractional load of streams was recently published by Max Singer, C. E., in "Zeitschrift für Gewässerkunde," Vol. 11, 1912, pp. 233-275, and that out of 31 entries only 6 gave the relation between the two loads, the range being from 1.0 to 0.11, as in the foregoing.

Interesting studies were also made at Berkeley of the vertical velocity curves in the experimental channels and the pitot gage used therewith, and although the results of the experiments are mostly applicable to flume transportation, yet the book contains so much other valuable material that it will be an important acquisition to every student of river physics.

CAMBRIA STEEL: A Handbook of Information Relating to Structural Steel Manufactured by the Cambria Steel Co. Containing Useful Tables, Index Data and Formulas for the Use of Engineers, Architects, Builders and Mechanics. Prepared and Compiled by Charles E. [illegible], General Manager. Cambria Steel Co., Johnstown, Penn. Eleventh Edition. [illegible] pp. [illegible] illustrations. [illegible]

The 11th edition of the well known Cambria Steel Handbook has just been published. It appears to contain most of the matter of the previous edition, but has been revised in some particulars and has had considerable new matter added. The new matter consists mainly of the sections of new and heavier sections, tabulation of the properties of standard railway rails, and the amplification of the tabulation of American municipal building laws. Such standard specifications as have been revised since the previous edition have been changed to meet the new revision.

A German Pocket-Book for Mechanical Engineers

Reviewed by Winslow H. Herschel*

TASCHENBUCH FÜR DEN MASCHINENBAU—Herausgegeben von Ing. H. Dubbel. Berlin: Julius Springer. In two parts. Cloth; 5x8 in.; pp. xi + 1462; 2448 text figures and 4 tables. 16 Marks.

In the attempt to cover all branches of engineering, the well known German pocket book, Hutte, has grown to three volumes, but Engineer Dubbel, by confining his attention entirely to mechanical engineering, is able with only one volume of somewhat larger size, to go much more into detail in regard to the subjects considered. He evidently takes Hutte as a model, and aims to give the best methods, rather than a compilation of all the suggestions to be found in engineering literature. It is also his idea that such subjects of general application as mathematics, mechanics and elements of machine design, should be treated very fully, while special types of machinery should be briefly reviewed so as to give any engineer a fair idea of them, since specialists on particular forms of apparatus are acquainted with the books dealing exclusively and in great detail with their machines, and they would never go to a handbook for their information.

This point of view has a far reaching and beneficial influence on the arrangement of the book. The first section, mathematics, is very complete, and includes among subjects not usually found in handbooks, the graphical solution of equations, probabilities, least squares, Fourier series, and an extensive discussion of analytical geometry as applied to engineering problems. Much that is given under mechanics might be looked for elsewhere. Here, instead of under materials, may be found the calculation of springs and tables of permissible stress; the strength of rapidly rotating disks, which are most frequently used in steam turbines; the latest researches on journal friction by Stribeck, Lasche and Heimann; and the graphical method of calculating the stress in crane hooks.

Such fullness in the chapter on mechanics naturally leads to shorter chapters on special machines. Steam engines are covered in about a third of the space usually taken, the bulk of the material coming under thermodynamics in the chapter on mechanics. And yet the chapters on separate machines are very full in regard to details of construction which apply only to these particular types of machines, as in the case of valve gears, under reciprocating engines, or air chambers, under steam pumps. On the other hand, parts which have more general application are placed in the chapter on machine elements, which covers, in addition to the details which may be found in any book on the steam engine, such parts as riveted joints, couplings, bearings, springs, shut-off valves, belts and belt shifters. The application of Mohr's graphical method to the determination of deflection of crankshafts is considered at some length. In fact, throughout the book, free use is made of graphical methods, and of problems to illustrate the methods given.

*Assistant Physicist, Bureau of Standards, Washington, D. C.

The design of hydraulic turbines occupies considerable space, since this is considered in Germany as the work of mechanical, rather than of civil engineers. Other subjects not usually covered with any degree of completeness in handbooks, are flywheels and governors, hoisting machinery and machine tools.

In the opinion of the reviewer, the book contains as much information as could reasonably be expected in an uptodate handbook for mechanical engineers, well selected and well arranged.

A Manual for Health Officers

PRACTICAL SANITATION: A Handbook for Health Officers and Practitioners of Medicine—By Fletcher Gardner, Captain Medical Corps, Indiana National Guard; First Lieutenant Medical Reserve Corps, United States Army; Health Commissioner of Monroe County, Ind., and James Persons Simonds, Professor of Preventive Medicine and Bacteriology, Medical Department, University of Texas; lately Superintendent Indiana State Laboratory of Hygiene. St. Louis, Mo.: C. V. Mosby Co. Cloth; 6x9 in.; pp. 403; 37 illustrations. $4.

The information and opinions given in this volume are for the most part rational and up to date. By means of concise treatment and the omission of considerable matter common to earlier treatises but, to say the least, not demanding repetition here, the authors have covered a wide range of sanitary topics in relatively brief space.

The book is divided into three parts: (1) Epidemiology, composing half of the volume; (2) General Sanitation, and (3) A brief section on Pathological Materials and some schedules for sanitary surveys and inspection. Most of Epidemiology deals with specific communicable diseases, but there are brief chapters on how to manage epidemics, on isolation and quarantine, hospitals and camps, and on disinfection. General Sanitation includes two or three pages on organization of the sanitary service, several short chapters on reporting vital statistics and 15 chapters on disposal of the dead, school and factory inspection, rats, flies and mosquitoes, soil pollution (privies) sewage and garbage disposal, milk, water, foods and nuisances. The longest of the 15 chapters has about 16 pages; several chapters are 2 to 5 or 6 pages in length.

As has been stated, Epidemiology takes up half of the volume. Such an allotment of space is proper enough if well utilized but as the book seems to have been written for physicians (serving as health officers or practicing medicine) it seems as though too much of this space was given to general notes on specific communicable diseases and not enough to methods of suppression.

Although we are inclined to approve rather than disapprove the brevity of most of the chapters dealing with General Sanitation, we must say that there seems to be some lack of balance in distribution of space here and also a lack of judgment in some of the facts and opinions expressed. Thus, one of the longest chapters under General Sanitation deals wholly with Water Analysis, and this is about all the book contains on water-supply. A chapter of half the length on Sewage Disposal lays too much stress upon the septic tank and subirrigation for isolated houses and mentions no other possible method of treatment.

Perhaps the most remarkable thing about the book, and one which we certainly shall not lay up against the authors, is the absence of not only a chapter but, so far as we can find, even a paragraph on plumbing. The word does not appear in the index.

It seems pertinent to ask, for whom was this book intended, what is its exact aim and how nearly does it serve its intended readers and fulfill its object? The subtitle reads: A "Handbook for Health Officers and Practitioners of Medicine." The preface declares:

This book was designed to fill a vacancy in literature. Up to the present there has never been a serious endeavor to provide within the covers of a single moderate-priced volume, a plain, nontechnical exposition of the duties of the health officer, written by one experienced in the routine and emergencies of the local sanitary service and familiar with the needs of the local health officer.

After a proper enough disclaimer of originality the Preface continues:

It aims simply to provide a safe way for the health officer to meet any emergency which may arise. Since sanitary officials in small places out of the reach of libraries are most in need of such a work, and since they are illy paid, the authors have endeavored to provide a book at a moderate price. . . .

It seems only fair to the authors to say that the foregoing statement of their aims partly answers some of our criticisms of their book and to add that they have gone far toward attaining their object. They would have gone still farther toward meeting the needs of medically trained health officers in our smaller American towns, it seems to us, had they cut out still more of the traditional general information about specific diseases and general sanitation and used the space thus saved for a fuller presentation, to repeat once more a few words from their Preface, "of the duties of the health officer" and "safe" means for him to take in meeting "any emergency which may arise." A large percentage of the information presented has only a remote bearing upon the actual duties of the average health officer as he sees and tries to meet them and a still larger percentage will be of little if any use to him in his routine work—much less in emergencies. This only means that the highly commendable work the authors have done in cutting out much of the kind of matter given in earlier treatises for health officers might have been carried further with great advantage, as might the insertion of more material which in plain terms tells the poorly informed average American health officer what he ought to do and how he ought to do it.

TECHNICAL MECHANICS, STATICS AND DYNAMICS—By Edward R. Maurer, Professor of Mechanics, University of Wisconsin. Third edition. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. 353; text illustrations. $2.50.

As a textbook for teaching mechanics, Prof. Maurer's book carries the impress of his long experience in teaching the subject to engineering students. The fundamental principles are stated, demonstrated and impressed on his mind, and applied in the solution of various special problems of technical construction or operation. Out of the great number of such problems met in practice, only a few can be dealt with in any single textbook, and the selection made by an author is apt to determine the reference value, if not the teaching value, of his book.

In Maurer's book, practically the only problems taken up for their own sake are suspended ropes and gyrostatic devices; other applications are used only to illustrate and make more concrete the instruction in the fundamental concepts and principles. In spite of this, the book has considerable reference value to the engineer in practice.

As compared with the first edition (reviewed in these pages, Jan. 14, 1904), the present edition is largely rewritten, and reillustrated, and is equipped with new working examples. The rewriting has been rearrangement as well as rewording of detail explanations; but since there is nothing new in the science of mechanics.

the chief fact to be noted concerning the rewriting is that the author's clear style of discussion characterizes this edition just as strongly as the first.

The larger changes announced in the preface are that a chapter on Attraction and Stress has been omitted, and a treatment of the gyrostat—not a very convincing treatment, by the way—has been added.

British Shop Costs and Production

REVIEWED BY ROSSITER R. POTTER*

ENGINEERS' COSTS and Economical Workshop Production —By Dempster Smith, M. I. Mech. E., Lecturer in Mechanical Engineering, Manchester Municipal School of Technology, and Philip C. N. Pickworth, M. Sc. Tech. [The "Mechanical World" Series.] Manchester and London: Emmott & Co., Ltd. Cloth; 6x9 in.; pp. xi + 248; 32 text illustrations. 4 Shillings, net.

From an American point of view, the value of this book is considerably restricted due to the differences between American and British industrial conditions and practice. The first four or five chapters on specifications, grades and prices of metals (chiefly of iron, steel and copper) apply, of course, simply to British conditions. The middle section, taking up the subject of machine-shop production, will be the most interesting to American readers, and in particular Chapters VI and VII on wage systems and shop organization and Chapter VIII, which presents a condensed discussion of Taylor's experiments with cutting tools and of the Berlin and Manchester experiments.

Chapters VIII to XII are based on a series of articles published in the *Mechanical World* some three years ago. Of these, Chapters X and XI give formulas for computing "standard times" for a few machine and hand operations. The times obtained by the use of these formulas, however, seem to be much too large if the work is to be done on a piecework or bonus basis. Much depends, of course, upon the nature of the piece to be worked upon. The formulas may be correct for the particular class of work the authors had in mind, but this they do not clearly define. Any engineer or manager who accepts these or any other general formulas at their face value and uses them to establish standard times for piecework in his own shop will be quite apt to come to grief.

The last part of the book takes up cost keeping, with a couple of chapters on British railway rates and on the shipment of goods from British ports. The chapters on cost keeping are decidedly elementary and of little use except perhaps to give a general idea of the subject to one entirely unfamiliar with it. In general, this book will not be of much importance to engineers or managers on this side of the Atlantic. But ignoring for the moment the present unsettled conditions due to the European war, the information on British metal markets, [illegible] methods and wage rates would be of interest to anyone contemplating a connection with some English engineering works.

[illegible]

[illegible] bulletin of the Mellon Institute series, [illegible] the progress of the Pittsburgh smoke and smoke [illegible] in general, [illegible] the first specific figures on the trouble makers in Pittsburgh. The bulletin gives a brief review of the agitation for improvement, summarizing the evidences of trouble, outlines some contributing causes of the evil like quality of fuel and local topography, and classifies the sources of smoke. All this, a little less than half the book, is preliminary to the discussion of a mechanical engineer's survey of stationary boiler plants. Here are described typical constructions and operating results with (1) hand fired; (2) chain-grate stoker; (3) front-feed stoker; (4) side-feed stoker and (5) underfeed stoker plants. The relative undesirability, as there operated, ranged in the order (3), (1), (2), (4), (5). One notable feature of the bulletin is a series of Pittsburgh views, taken from identical positions on clear and smoky days.

*[illegible]

A New Edition of Moyer's Steam Turbine

REVIEWED BY H. E. LONGWELL*

THE STEAM TURBINE. A Practical and Theoretical Treatise for Engineers and Designers, Including a Discussion of the Gas Turbine—By James Ambrose Moyer, M. Am. Soc. C. E., Professor in Charge of Department of Mechanical Engineering, Pennsylvania State College. Second edition, revised and enlarged. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. xi + 376; 225 illustrations. $3.50, net.

The fact that the publishers have been encouraged to put out a second edition of a technical book is, as a general proposition, the best kind of evidence that it is a useful work. The first edition of Professor Moyer's treatise was published in 1908, and was reviewed in ENGINEERING NEWS of March 18, 1909.

This second edition does not differ much from the original, except by way of some additional pages of descriptive matter, and the insertion of a number of practice problems. The first six chapters are unchanged except for a couple of small additions to Chapter II, on the Elementary Theory of Heat, and Chapter III, on Nozzle Design. Chapter VII, on Commercial Types, has been augmented by 14 pages of new text and illustrations. Chapter IX, on Low-Pressure Turbines, has been enlarged to twice its original size, and gives a much more comprehensive discussion of this machine and the circumstances which justify its use.

Two new chapters have been inserted which treat briefly of Mixed-Pressure Turbines and Bleeder or Extraction Turbines—developments that were in the embryonic stage at the time the first edition of the book was published. The chapter on Marine Turbines has been enlarged from two pages in the first edition to eight pages in the present edition, and is still very brief, considering the enormous development that has taken place in this application of the steam turbine during the past eight years.

The final four chapters, dealing with Turbine Economy, Stresses in Rotors, Drums and Disks, Gas Turbines and Electric Generators, are practically identical with the corresponding chapters in the first edition. In view of the considerable advance in high-speed generator design and construction in recent years, it would seem that the author might have enlarged a little on this subject.

An appendix of six pages of practice problems enhances the value of the work as a textbook. An unusually well engraved entropy-total heat diagram, on a conveniently large scale, accompanies the book.

*[illegible] Westinghouse Machine Co., East Pittsburgh, Penn.

The subtitle, "A Practical and Theoretical Treatise for Engineers and Designers," is a trifle pretentious if the author refers to engineers who design and construct steam turbines. The work is hardly comprehensive enough to warrant this characterization. It treats the subject in a conventional manner, and is undoubtedly an efficient elementary textbook for students, or for power-plant engineers, who, while not wishing to specialize on steam turbines, may find it advantageous to have a good general knowledge of their theory, construction and practical application.

Engineering Geology

ENGINEERING GEOLOGY—By Heinrich Ries, Professor of Economic Geology, Cornell University, and Thomas L. Watson, Professor of Economic Geology, University of Virginia, and State Geologist of Virginia. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. xxvi+672; 175 illustrations. $4 net.

Many, if not all, the larger colleges offer no end of "courses" in geology, but too many engineering schools either fail to provide a course in geology suited to the needs of their students or else leave the ordinary student no time to take such a course if one is offered. This is unfortunate, because of the many relations of geological knowledge to sound engineering design and construction, as the nature of rocks available for road making, or to serve as foundations for heavy structures or to be pierced by tunnels.

A book which treats of geology chiefly from an engineering viewpoint is, therefore, a most welcome addition to our engineering literature, especially when that book is so complete and authoritative as to serve not only for a college textbook, but to form a valuable reference work for any engineer's library. As Dr. Ries is already known to many engineers through his splendid book "Economic Geology," and his books on building stones and clay products, little more need be said of the merits of the book before us.

A synopsis of the contents follows:

Rock-forming minerals, essential principles of crystallography (45 pp.); the general characteristics, mode of occurrence and origin of rocks (100 pp.); the structural features of metamorphism of rocks with references to engineering experience on the Catskill and Los Angeles aqueducts, etc. (68 pp.); rock weathering and soils, which a topographical engineer should understand to fully appreciate topographical features of the maps he draws (29 pp.); surface waters (rivers) including the geology of runoff and stream flow, erosion, transportation of sediment, delta formation, etc. (51 pp.); underground waters, treated from every viewpoint as sources of water-supply (47 pp.); landslides and their effects, (16 pp.); wave action and shore currents and their relation to coasts and harbors (38 pp.); the origin and relation of lakes to engineering work (18 pp.); the origin, structure and economic bearing of glacial deposits, containing much material of interest in connection with subsurface construction (15 pp.); building stone, their kinds, sources, properties and uses of various North American stones (64 pp.); limes, cement and plaster, their composition, sources, manufacture and properties (17 pp.); clay and clay products, their properties and uses (17 pp.); coal series, kinds of, origin, distribution in the United States, uses, etc. (35 pp.); petroleum, natural gas and other hydrocarbons, properties, occurrence, including solid and liquid bitumens (25 pp.); road foundations and road materials, geological conditions which affect permanence and stability, kind and character of rock, gravel and sand (27 pp.); ore deposits, nature and occurrence of all the more important metal ores, but not a detailed discussion of their distribution (42 pp.)

We have given the synopsis at some length because a glance through it will show the completeness of the book. Each chapter includes a list of references to more detailed information.

The only objection to this book is its weight, not metaphorically speaking, but actually, for it weighs upward of 3 lb. We have noted this objection to some engineering books before. We believe it is a serious objection, for most engineers are obliged to carry their working library from place to place, and even a few such books constitute too great a load for the average trunk. Even if the book is not to be carted about the country, it is still inconvenient, for no one wishes to hold a 3-lb. weight when reading.

DAS SPIEL DER KRAFTE IM VERBUNDBALKEN; Eine Darstellung der Lehre vom Verbund, von der Spannungsverteilung und Ermittlung in auf Biegung beanspruchten Eisenbetonkörpern—Von Georg Fischer, Regierungsbaumeister, a.D. in Posen. Lissa-in-Posen, Germany: Oskar Eulitz. Pasteboard; 7x10 in.; pp. 77; 53 text figures. 6 Marks.

Regarding the reinforced-concrete beam as an arch in its central portion and a beam with concrete and steel jointly in tension in the end portions, the author locates the stress transfer from concrete to steel mainly in the region near the ends of the arch, instead of finding maximum bond stress at the ends as is usually thought. He further reasons that end anchorages, deformed bars, etc., are either useless or unnecessary expedients. He prefers designing beams for the range below tensile rupture of the concrete, limiting the steel stress to the limiting safe elongation of the concrete; the elastic ratio is still to be determined by test, he declares. In such design, the tensile strength of the concrete is to be counted in figuring the moment.

A new good-roads periodical under the name of "Dependable Highways" has made its appearance. This is the official bulletin of the National Paving Brick Manufacturers' Association, published by the Secretary of the Association, Engineers' Building, Cleveland, Ohio. It is sent gratis to municipal officials, engineers, highway commissioners, contractors and manufacturers, and doubtless to any engineer requesting to be placed on the mailing list. The paper is, of course, devoted chiefly to brick roads and pavements, but it is announced that attention will be given to other phases of road work. Indeed the first issue, dated August, 1914, contains an article by J. T. Fetherston, Commissioner of Street Cleaning, New York City, on "Litter Prevention as a Street Cleaning Factor," which displays an intention to include other than articles exploiting brick-road construction. It was announced at the convention of the Society held in Buffalo, Sept. 9, 10 and 11, that the bulletin is already on a self-supporting basis.

The new specifications for brick pavements of the National Paving Brick Manufacturers' Association have been issued in booklet form and may be obtained by addressing the Secretary, Will P. Blair, Engineers Building, Cleveland, Ohio. The present booklet represents two years' work of a committee appointed to revise and draft new specifications. The specifications cover excavation, grading, drainage, and curbing, as well as pavement and foundation. The clauses in the specifications covering the testing of materials are adopted chiefly from those proposed by the committee of the American Society for Testing Materials.

Bituminous expansion joints at the curbs are specified, but transverse expansion joints are expressly prohibited. Cement grout and sand fillers only are provided for; the association does not recommend or advise bituminous filler

[illegible] pavements. The specifications for [illegible] [illegible], broken stone, old gravel or macadam and No. 2 paving brick. There are two distinct sets of specifications, one for city pavements and one for country roads.

[illegible]

[illegible] VALVE GEARS AND VALVE SETTING: A Practical Treatise Which [illegible] the Mysteries of Valve Setting, Shows the Different Valve Gears in Use, How They Work and Why; [illegible] and Slide Valves of Different Types are Illustrated and Explained—By Fred H. [illegible], Associate Editor "American Machinist." Third edition, [illegible] and enlarged. New York: Norman W. Henley Publishing Co. Cloth; [illegible] in.; pp. [illegible]; [illegible] illustrations. [illegible]

Three new chapters have been added to this book, which, in other respects, is the same as at the time of its first appearance more than ten years ago. The new matter relates to the Walschaerts, the Baker, and the Southern locomotive valve gears. The increasing size of locomotives has led to a wide application of the Walschaerts gear, which is placed on the outside of the connecting-rod in an accessible position. The other two valve gears mentioned are not extensively used, but their existence justifies their description.

NEW PUBLICATIONS

(So far as possible the name of each publisher of books or pamphlets listed in these columns is given in each entry. If the book or pamphlet is for sale and the price is known by the editor the price is stated in each entry. Where no price is given it does not necessarily follow that the book or pamphlet can be obtained without cost. Many, but not all, of the pamphlets, however, can be secured without cost, at least by enclosing postage. Persons who are in doubt as to the means to be pursued to obtain copies of the publications listed in these columns should apply for information to the stated publisher, or in case of books or papers privately printed, then to the author or other person indicated in the notice.)

VOLUME 72 SEPTEMBER 24, 1914 NUMBER 13

Making a Water-Tight Junction of a Large Steel Pipe and a Rock Tunnel under a High Head

By Arthur W. Tidd*

A number of valleys are crossed by the aqueduct for the new water-supply for New York City in the course of the 92 mi. from the Ashokan Reservoir in the Catskill Mountains to the Hill View Reservoir at the New York City line. One type of aqueduct for such crossings is a line of riveted steel pipe laid across the valley at the surface of the ground. At such crossings, the pipe line is laid directly down the slope to the bottom of the valley and up the opposite slope to the hydraulic gradient, connection at either end with the cut-and-cover type of aqueduct being made through a siphon chamber at grade. In one case, however, the steel pipe terminates near the bottom of the valley and joins a pressure tunnel (Fig. 1). It is the method of making a water-tight connection between the pipe and the tunnel at this point with the aqueduct in service under a head of about 168 ft., that this article describes. The steel pipe is the Bryn Mawr siphon and the tunnel the Yonkers Pressure tunnel. The location is about four miles north of the New York City line and about two miles east of the center of the City of Yonkers.

Conical Portion of Steel Interlining, Junction of Bryn Mawr Siphon and Yonkers Pressure Tunnel, Catskill Aqueduct

(Looking from cylindrical portion toward the connection chamber. The sections are bolted in position ready for riveting.)

Design in Brief—The sectional plan at mid-height of the waterway and the vertical section on the center line of the aqueduct (Fig. 2) show the design in outline, which is, in effect, the continuation of the steel pipe of the siphon through the connection chamber and about 175 ft. into the tunnel, the pipe being completely embedded in the concrete lining of the tunnel. Four heavy special pipe castings and a 72-in. hydraulically operated gate valve are inserted in the line at the chamber. The steel lining of the tunnel, called the steel interlining, terminates in a steel diaphragm projecting outward all around at right angles to the axis of the tunnel. The interlining is designed to be absolutely tight against

*Section Engineer, Board of Water Supply, 215 Kimball Ave., Yonkers, N. Y.

[illegible] after erection and before embedding in concrete.

The enlarged longitudinal section (part of Fig. 2) shows the principal features inside the tunnel. The rough excavation is smoothed up by a concrete lining, the steel interlining erected, the 2-in. annular space grouted and the 8-in. concrete inner lining placed to form the waterway. The steel diaphragm projecting outward into a narrow groove in the rock marks the end of the steel interlining and the end of the special measures designed to effect a water-tight junction of the pipe and the tunnel. Beyond the diaphragm, the construction is of the ordinary concrete-lined tunnel type, the three branch tunnels joining at the bellmouth to form the standard tunnel of 16 ft. 7 in. finished diameter.

The tunnel is in rock, of the Yonkers gneiss formation, somewhat faulted at the portal, but not enough to require timbering, and sound at the bellmouth. The two side branch tunnels, constructed for the two additional pipes of the Bryn Mawr siphon to be built in the future, are similar in every way to the center tunnel, including the heavy castings and the gate valve.

SPECIAL CASTINGS IN THE CONNECTION CHAMBER.—The 11-ft. 3-in. diameter, ½-in. butt-jointed, steel pipe of the Bryn Mawr siphon draws down by means of a special reducing section, about 13 ft. long, to a diameter of 8 ft. 10⅞ in., terminating in a calking ring of ¾-in. plate, 9 in. wide, riveted with countersunk rivets on the outside of the ½-in. shell of the pipe (see Fig. 3). The calking ring enters the socket of the first of the special castings, the reducing wall pipe. This socket is of unusual depth (24 in.), to enable the lead joint to be calked on the inside (see Fig. 4). The next casting is the expansion piece, of ordinary design, followed by a 72-in. hydraulically-operated gate valve. Next to the valve is the manhole pipe, the manhole, 36 in. in diameter, giving the only access to the tunnel other than through the intake shaft at Hill View Reservoir, when the gate valve is closed. The increasing wall pipe, the last of the line, follows. This casting has a socket end for the manhole pipe and a flanged end for the connection with the steel interlining of the tunnel which immediately follows.

The average weight of the various pieces is as follows:

	Lb.
Reducing wall pipe	[illegible]
Expansion piece	[illegible]
72-in. gate valve	[illegible]
Hydraulic cylinder	[illegible]
Manhole pipe	[illegible]
Increasing wall pipe	[illegible]

[illegible]

[illegible]

$1/8$-in. soft copper wire were used under the bolt heads to prevent leakage along the bolts. The joint between the reducing pipe and the expansion piece was poured, but with unsatisfactory results. A similar joint on one of the side lines was also poured, but with equally unsatisfactory results. Both side- and top-pouring-hole methods were used, and both joints had to be melted out and repoured, but finally an acceptable result was obtained. The rest of the joints were made with lead wool, calked with pneumatic calkers operated by compressed air under about 80 lb. pressure. The gasket for the joint at the manhole cover was a copper ring, H-shape in section and about ⅜ in. thick. The largest lead joint (diameter 9 ft. 2⅝ in.) was unusual on account of its size and also on account of its depth, about 8 in. Special calking tools were required to be made for this joint, and about 1200 lb. of lead wool were used. About 150 lb. were driven into the smallest joint.

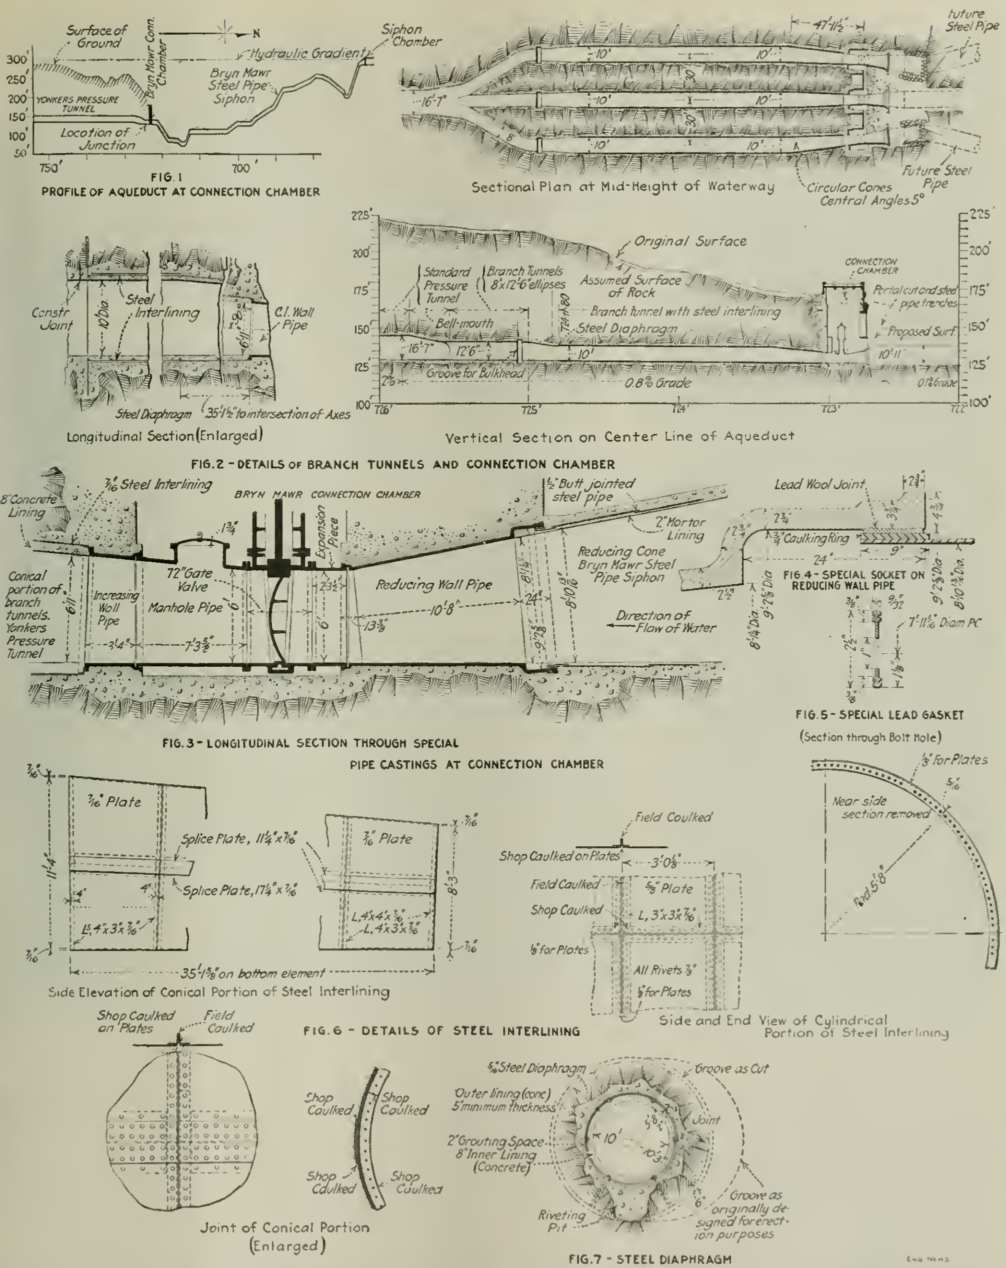
Fifty-six 1⅞-in. steel bolts were used on each flange of the 72-in. gate valve; thirty-two 1½-in. steel bolts with bronze nuts were used on the manhole cover and ninety-two ⅞-in. steel bolts were used to connect the increasing wall pipe to the end angle of the steel interlining.

The lead joint on the manhole pipe and on the expansion piece were made solid against longitudinal movement by driving many wrought-iron wedges between the spigot end and the base of the socket on the inside of the pipe.

OUTER CONCRETE LINING OF TUNNEL.—The first operation in the tunnel after excavation was the placing of the outer concrete lining of 5 in. minimum thickness to the rock and 11 ft. 8 in. inside diameter for the 110 ft. between the end of the conical portion of the steel interlining and the steel diaphragm, both to be described later. The cross-section was circular. The invert was first laid, 5 ft. in width, screeded and finished, using side planks set radially for forms. The "Jackson" forms were then set up for placing the rest of the section. The Jackson forms consisted of full-circle ribs of the diameter of the tunnel, made up of 5-in. I-beams with a 5-in. I-beam post in the center and two 5-in. channels riveted together back to back, set across the horizontal diameter. Bolted joints permitted the form to be dismantled, taken through the forms in use and reassembled for the next stretch. The forms were set at 5-ft. intervals. For the lagging, ⅛-in. steel plates [illegible] in. wide by [illegible] in. long, curved to the radius of the tunnel and stiffened by 1½ x 1½-in. angles, were used. The lagging was placed as the concrete rose.

A small amount of water from a general seepage and a few [illegible] was encountered, but gave no difficulty [illegible]. [illegible]

STEEL INTERLINING.—The steel interlining (see details, Fig. [illegible]), starting at the increasing wall pipe with a diameter of 9 ft. [illegible] in., increased in a distance of about [illegible] ft. to a diameter of 11 ft. [illegible] in. and continued with that diameter to the terminal steel diaphragm, a distance of about 100 ft. The first or conical portion was made of [illegible]-in. plate, butt-jointed, [illegible] about [illegible] ft. long [illegible]. The remainder or cylindrical portion was made of [illegible]-in. plate



FIGS 1 TO 7. JUNCTION BETWEEN BRYN MAWR STEEL SIPHON AND YONKERS PRESSURE TUNNEL, CATSKILL AQUEDUCT

and in segments, as described later. All had inward-turned angles for connecting and riveting the sections in the tunnel.

The first operation in the conical portion of the tunnel was the placing of a strip of the invert of the concrete outer lining from a point near the south wall of the connection chamber to the already completed concrete of the cylindrical portion. The invert was laid and screeded to a radius 2 in. larger than the steel. Across the invert were laid short lengths, about 5 ft. for the largest radius, of 6-in. 8-lb. steel channels with flanges (2 in. in width) upturned, bent to the radius of the steel interlining,

in which segments the sections of the interlining were erected. Beginning at the intersection of the cone and cylinder, one section of the cylindrical portion of the interlining having been first carefully placed and trued up in order to make a correct start, the first of the 6-ft. lengths of the cone was erected and the entire surrounding space between the steel and the rock filled with concrete. The 2-in. space beneath the steel on the invert was filled by pouring in thick grout and churning it thoroughly to insure complete filling. For the sides and arch, the concrete was placed by the usual methods, especial care being taken to tamp it thoroughly and to make a tight contact with the steel. The procedure was similar for each of the remaining sections of the cone, the section at the portal of the tunnel being the last to be placed and concreted. A grout pipe, to be described later, was placed in the top of each section extending to the rock.

The cylindrical portion of the steel interlining consisted of sections 3 ft. in length, each section being composed of six segments which, when riveted together, formed a circle of diameter 11 ft. 4 in. Each segment was of ⅝-in. plate, curved to the radius of 5 ft. 8 in., with a 3x3x⅝-in. angle riveted to each of the four edges of the plate. The angles were mitered at the corners and projected ⅛ in. beyond the edge of the plate all around. All joints were also calked where possible, a fundamental principle in the design, construction and inspection being to make the interlining in itself tight against leakage. In erecting the sections, 5 ft. lengths of 6-in. [illegible] curved channels were laid across the invert, as described for the conical portion. These formed the 2-in. grout space on the bottom, a feature of this portion of the design being an annular space 2 in. wide between the steel interlining and the outer concrete lining of the tunnel, filled with grout after the steel was erected and calked. The segments were erected without difficulty. All joints throughout the entire length of the interlining were riveted with the exception of the one at the intersecting main pipe. Pneumatic tools were used for all the riveting and practically all the calking. Soft steel wedges were driven into the openings at corners, etc., and calked. The thorough character of the work was proved by the very small amount of leakage when the 2-in. annular space was grouted.

STEEL DIAPHRAGM—At the termination of the steel interlining, a circular steel diaphragm or water stop was erected (Figs. 7 and 8), projecting about 4 ft. 6 in. beyond the interlining and at right angles thereto into a narrow groove cut in the rock. The diaphragm was riveted and calked to the steel interlining and grouted into the groove at the same time that the 2-in. annular space around the interlining was grouted.

The cutting of the groove proved to be very slow and expensive. The specification in the contract covering this work was as follows:

Sec. 75 A. The channels to be constructed under this item shall be of such depth as to permit the insertion of a diaphragm [illegible] ... top of the surrounding rock. They shall be completely cleaned of all debris and shall be kept clean until refilled, in accordance with orders. These channels shall be cut at such times that the erection of the steel interlining and the completion of all other work in the branch tunnels shall not be delayed.

The method to be used was the subject of much discussion. The cutting was finally done with ordinary rock drills mounted on columns, so as to permit radial cutting, the operation being that of cutting away the entire rock as with channeling machines. No other method was tried. The groove was started with a 3½-in. bit and somewhat smaller bits were used as the channel deepened. Two drills were usually used on one column. One of the greatest difficulties encountered was in guiding the drill so as to cut in a plane. Guides made of steel angles between which the drill could run, placed close to the rock, were tried but given up. The method finally adopted was to use the end of the steel interlining in its finally erected position as a guide, holding the shank of the drill against it while drilling. The hardness and texture of the rock varied, oftentimes within the space of a few inches, and occasional seams were encountered. Both these operated to throw the drill to one side and deflect the channel from its true plane. When this occurred, the only way to get the groove back onto line was to drill small shallow holes as nearly parallel to the plane of the groove as possible, shoot off the projecting rock with light charges, and make a fresh start with the drill. In spite of all the pains taken, difficulties were encountered from this source when rotating the diaphragm during erection. The average depth of cut was about 4 ft. for the groove in the east branch tunnel, 4 ft. in the center tunnel and 2.5 ft. in the west tunnel, the maximum cut being 4.5 ft. and the average area of groove cut (area of plane normal to axis of tunnel) 173.4 sq.ft. The average time per groove required for cutting was equivalent to 101 eight-hour shifts for one driller and one helper.

The steel diaphragm was ⅜ in. thick, 20 ft. 6 in. in diameter, and composed of six segments with field-riveted joints. The original design contemplated cutting the groove on one side of the tunnel to a sufficient additional depth, 4 ft. at the maximum, to permit the diaphragm to be rotated and shifted as each segment was attached and the radial joint riveted, until the full circle was completed, whereupon the diaphragm would be shifted back, brought into position and riveted to the interlining. It was apparent very soon after drilling commenced that it would be extremely difficult to cut the groove to such a depth and modifications of the method were studied, with the result that the contractor was permitted to excavate a riveting pit in the invert about 4 ft. square and 4 ft. deep. In this pit, each joint was exposed for riveting by rotating the diaphragm on the end of the interlining. Even with this modification, some trouble was experienced as the diaphragm was rotated, due to irregularities and projections in the groove.

GROUTING THE 2-IN. ANNULAR SPACE—The next step was to complete the lining of the tunnel up to and against the south side of the diaphragm, but not filling the groove. To prevent the entrance of concrete into the groove during concreting, the opening on each side of the tunnel from the invert well up to the crown was closed with brickwork about 8 in. square laid against the diaphragm and following the irregularities of the rock. The portion of the riveting pit and the diaphragm groove be-

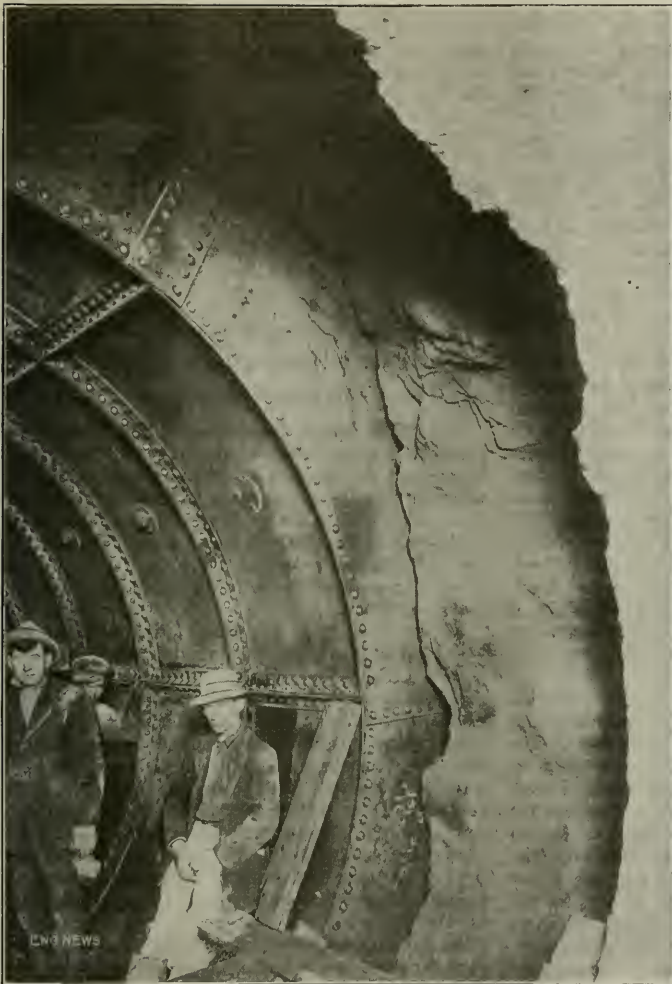


Fig. 8. End of Steel Interlining, Showing Steel Diaphragm Riveted into Place

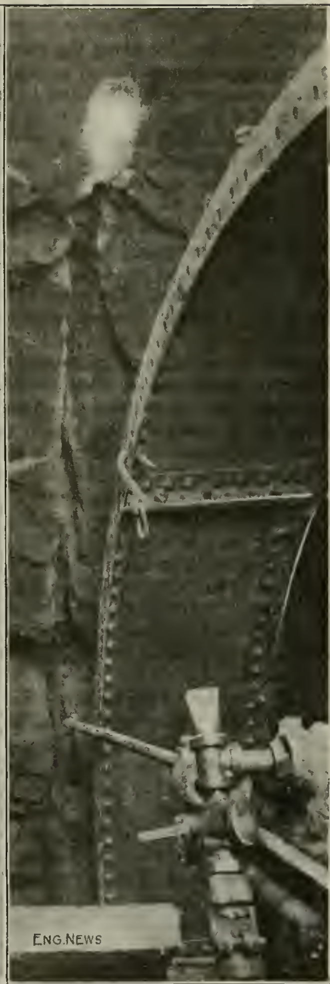

Fig. 9. Cutting Groove for Steel Diaphragm

low the invert was filled with 1 to 1 grout poured in through a grout hole in the bottom of the steel interlining. Grout pipes extending the full depth of the groove were placed in the invert, at the springing line and in the roof and concreted in.

After the concrete was thoroughly set, the 2-in. annular space outside the steel interlining was filled with grout, using the 2-in. grout holes provided in the segments of steel interlining for that purpose. These holes were formed by a threaded casting riveted to the steel to which the grouting apparatus was attached. A liberal number of segments with grout holes were provided and during erection they were placed at frequent intervals in the invert and arch and in the upper and lower quarter points. The spacing was not over 30 ft. for a maximum and usually much less. Grouting was begun at one end with a connection at the invert and to avoid forcing the grout to travel too far at least three connections were made. All holes were kept open as the grout rose and were not closed until a free and continuous flow of well mixed grout appeared. After the space was filled to a height of about 3 ft., connections were made to the holes in the crown and the grouting completed. The interlining was sounded with a hammer during the filling to expel the air and aid in insuring a complete filling at the top. After the grout had set, the grout holes were closed with cast-iron plugs. The grout was placed with a light pressure at first and reached a maximum of 60 lb. when finishing. The mix was 1 bag of cement, 1 bag of sand of about 0.9 cu.ft. volume and 85 lb. weight and about 12 gal. of water. Two grouting tanks of the Caniff type mounted on a movable truck were used, thus giving an almost continuous flow of grout.

Grouting Back of the Outer Concrete Lining—

After the grout had sufficiently set, holes were drilled through to the rock in order to grout any voids that might have been left along the rock during the placing of the outer concrete lining, especially in the roof, and also if necessary to fill the seams in the rock. In anticipation of this operation, 2-in. holes had been drilled and tapped in the steel interlining after erection by using a portable pneumatic drill and hand-driven special short taps. The holes were closed with a cast-iron plug during the grouting of the 2-in. annular space. The drilling was done chiefly with jap drills, a short length of 2-in. pipe being screwed into the hole to protect the threads and also to guide the drill. The holes were drilled through to the rock. The grout hose was connected directly to the hole in the steel interlining. A pressure of 200 lb. was tried first with the intention of forcing the grout as far as possible into the seams of the surrounding rock, but this caused an inward buckling of the steel interlining near the connection. Another hole was tried under 80 lb. pressure with a similar result but less in extent. The pressure was reduced to 50 lb., and no further trouble was experienced. The plates alone buckled, there was no deformation of the rib angles. The buckled areas were tapped where necessary and filled with grout. The grouting was completed using the 50 lb. pressure, and the holes closed with cast-iron plugs after the grout had set. Neat grout was used, mixed 1 bag of cement and 6 gal. of water. The 200 lb. pressure was produced by a Westinghouse high-pressure air compressor, taking power from the low-pressure air line at that time in service in the tunnel.

The Concrete Interlining—The final step was the placing and grouting of the [illegible] concrete lining inside the steel interlining to form the waterway. The steel was thoroughly cleaned and a strip of invert 4 ft. wide laid along the bottom. On this strip the forms were erected and the lining placed, the forms and method for the cylindrical portion being similar to that used for the outer lining, described in the first part of this article. The horizontal member of the form was in this case placed a little above the axis, and formed the support for the track and platform on which the concrete was delivered. In the curved portion, [illegible] wide wooden lagging were used. The concrete was mixed a little richer than 1 to 6. The coarse aggregate was 1 in. maximum diameter.

To secure complete filling around the legs of the angles on the steel interlining at the top, grout pipes were set when the concrete was placed and the space afterward filled with neat grout under about 50 lb. pressure. The pipes were set on the center line of every [illegible] of the interlining. At first, two pipes were placed about 1 ft. either side of the center, but later one additional pipe was used, one on each side just below the angle at the lower part of the arch segment. Grout pipes were also set in the invert portion and grouted at the same time as those in the cylindrical portion. Not all the holes appeared to be connected to, but at least one connection was made for every 3 ft. in length of tunnel and all holes not showing a flow of grout were [illegible].

Test—The hydrostatic test of the entire tunnel under the full working pressure indicated that the work was thoroughly done, for no leakage could be detected and [illegible]. The work was under about [illegible] head continuously for three months and under the full hydrostatic head of 168 ft. for the week next following. The grouting of the 2-in. annular space gave a very good demonstration of the tightness of the steel interlining under the moderate pressure used for that operation.

J. Waldo Smith is Chief Engineer of the Board of Water Supply, Frank E. Winsor, Department Engineer, and Chas. E. Wells, Division Engineer in charge of construction, Alfred D. Flinn, Department Engineer, Headquarters, and Thos. H. Wiggin, Senior Designing Engineer, were in charge of the design. The contractor was Geo. W. Jackson, Inc., of Chicago.

Manufacture, Test, and Use of Waterproofing Fabric

By Joseph Rosenzweig*

The Public Service Commission of New York (First District) is using enormous quantities (1,000,000 sq. ft. in the last six months) of treated woven fabrics for waterproofing the new subways now under construction in the City of New York. It was found difficult to get uniformity in the product, and a study of the subject was therefore made by the writer for the purpose of standardizing the manufacturing and testing of these saturated fabrics.

Waterproofing fabric is made of burlap saturated with asphalt or coal-tar pitch, and sprinkled with woodflour to prevent self-adhesion. Burlap is made of jute, which is the fiber obtained from the inner bark of the Asiatic plant, *Genus Corchorus*, of the Linden family. The woodflour is pulverized or granulated pulp, chiefly of cedar or white pine. Most of the burlap used for waterproofing is received from Dundee and Calcutta, in bales or rolls of from 1200 to 2000 yd. in length, the width being from 32 in. to 42 in. The finished fabric comes in rolls of from 100 to 200 yd. in length, the width varying sometimes from 29 to 30 in., the variation from the original width of burlap being caused by shrinkage due to saturation.

As the Public Service Commission is using coal-tar pitch for membrane waterproofing exclusively, it is highly desirable that the saturating flux and coating of the fabric should conform as closely as possible to the binder, and as heretofore no jute fabrics had been saturated and coated with coal-tar pitch, experiments were conducted to determine whether this could be done, and eventually it was found that fabrics of this nature could be produced, and it is now used on our work, together with asphalt-saturated fabrics.

Requirements of Fabric

It has been found that good waterproofing fabric [illegible] possess the following qualities:

1. The fabric should be thoroughly saturated and well coated, leaving sufficient open pores to permit the proper bonding of [illegible].

2. The fabric should be sufficiently pliable so as to conform to the [illegible] of the surface to which it is applied.

3. The burlap while being saturated should not be [illegible]

*[illegible], Public Service Commission of New York, First District, New York City.

charred, which may happen if the temperature of the saturant is very high.

4. The saturant should be of such material as not to have a deleterious effect on the burlap.

5. The finished roll of fabric should be easily unrolled, only sufficient woodflour to prevent self-adhesion being used.

6. The completed roll of fabric should be protected from warping, wrinkling or other injury by the insertion of a central core or spool made of wood or fiber.

7. The saturating flux should have a melting point of at least 140° F. and its temperature during the saturation process should be between 270 and 300° F.

To produce the above, experiments have shown that the burlap must be drawn through the saturant very slowly and remain immersed for as long a period as is required to draw a maximum of 10 ft. of the burlap through the saturant in 30 sec. when the saturant is at 270° F., the speed being proportionate to the temperature of the saturant, that is, the hotter the saturant, the less the time of immersion, and *vice versa*. This speed may be increased if the burlap is to receive a coating besides the saturation; that is, if the double process is to be used. The melting point of this coating flux (which is not to differ materially from the saturating flux) may be twice that of the saturant, but its temperature at the time of application must be the same as that of the saturant to effect complete adhesion.

Manufacture of Fabric

The method of saturating the burlap found to be most practicable and now in general use is as follows: A roll of burlap is passed through a series of hot rollers or hot coils for the purpose of evaporating all moisture, which sometimes amounts to 10% by weight, and never less than 3%. It is then rerolled (unless coils or rollers are near the saturating tank) and set up in a revolving stand in front of a long but shallow steel tank through which it is drawn at a depth of about 1 ft. below the surface of the saturating material contained therein, for a distance of about 15 ft. A short but very deep tank is equally as good as a long but shallow one, the burlap traveling through it vertically instead of horizontally. The saturant is heated and kept to any required degree of temperature by steam coils placed along the vertical walls of the saturating tank on the inside. From the tank it is drawn through two steam-heated compression rollers. The function of these rollers is to remove the excess saturant clinging to the burlap and press the remaining saturant into it. The pressure exerted by these rollers determines the percentage of open mesh remaining in the saturated product.

The saturated fabric is next drawn over an air space whose practical horizontal limit is about 20 ft. with the machinery used in most manufacturing plants, or drawn alternately over water-cooled rollers with bearings on floor and ceiling, whence it is sent over a series of drying rollers, which may be large or small, their function being merely to expose the saturated fabric for as long a period as is practicable to the cooling effect of the air. Instead of the open air space, a strong electric blower properly placed will accomplish the same result. The drying rollers are also used to spread on the surface a thin film of woodflour, after which the fabric is wound upon a collapsible spindle, from which it is easily removed, a simple measuring device showing that the required length has been rolled up. A core above referred to is then inserted, or the fabric may originally be rolled thereon, and the roll is then ready for shipment.

The burlap should show a uniform open mesh with a uniform thickness of thread in warp and woof, and in drawing it through the series of rollers for saturating purposes, care must be exercised not to subject it to too great a tension, as this distorts the mesh and weakens the fabric. The best burlap to use has been found to be that of between 7 and 8 oz. per sq.yd. incl. in weight. The saturating material may be either a pure or fluxed asphalt or a coal-tar pitch. There is no positive proof that asphalt is preferable to pitch as a binder or saturant, but in view of the fact that a coal-tar pitch is now used exclusively as a binder in the field for bonding the various plies of fabric, it is preferable as a saturant because asphalt and coal-tar pitch do not mix well.

Experiment has shown that while all asphalts are capable of being acted upon by acids, coal-tar pitch is affected by them to a much less extent. The asphalt should not be too brittle if fluxed; that is, if an asphaltic oil and gilsonite or grahamite are mixed in certain proportions to form commercial asphalt; the coal-tar pitch, on the other hand, should not contain more than 10% free carbon, because carbon, as well as the burlap proper, is not a waterproofing material, carbon giving body to the saturant, so to speak, and the burlap giving body or acting as reinforcement to the waterproofing membrane.

It may be asked, Why saturate burlap at all? To which the answer is, that workmanship in the field with reference to waterproofing a subsurface structure is not entirely dependable; the temperature of the binder is not constant, and often below what is necessary to saturate the raw burlap. It may also be asked why woodflour alone is satisfactory for preventing self-adhesion. Because anything else, such as soapstone, cork flour, powdered sand, or even coarse sawdust, is not absorbent, adds unbeneficially to the waterproofing membrane, and hinders the affinity between the binder and the saturating flux when the fabric is applied in the field. It should be noted, that experience with various woodflours has definitely demonstrated the superiority of one of a fine granular nature over any other form.

It has been suggested that creosote, being an excellent preservative of wood, and a distillate of coal tar, would be an equally good preservative for burlap. The objection to this lies in the fact that creosote evaporates very quickly, leaving the fabric stiff and unprotected against mechanical injury.

Tests for Acceptance

Experience has shown that the following inspection methods reveal whatever is good or bad in waterproofing fabric:

1. Observe the surface of the fabric through a magnifying glass and note whether the individual strands are merely stained or actually coated with the saturant, the former being entirely insufficient.

2. Hold a large piece of the fabric before a light and note the percentage of open mesh, which should be approximately 50% of the untreated burlap. This percentage of open mesh insures good coating, but not necessarily good saturation.

3. Cut off a piece of fabric about 1 ft. square from a roll selected at random, and with a sharp knife cut it parallel to the warp, parallel to the woof and diagonal to both. This will not always reveal insufficient saturation, but by tapping the fabric along the line of these cuts, the defect will become visible and show the fabric to be unsatisfactory.

4. Flexibility and a certain degree of softness of the fabric are essential properties. These may be discovered by crushing the fabric in the hand held close to the ear. If a crackling sound is heard, or flakes peel off, it shows that the asphalt is too hard or the coal-tar pitch is of too high a melting point. The fabric will also feel stiff if either is the case.

5. A square foot of the fabric should be cut from any portion of the roll and carefully weighed to determine the amount of saturation; this should equal the weight of the raw burlap, thus making the finished product twice the weight of the raw, and this should be a minimum.

6. Since an excessive coating of woodflour is undesirable, and even injurious, the finished roll should be examined, and if its appearance is distinctly white, as it is when too heavily covered with white pine woodflour, it should be rejected; the amount of woodflour permissible being 2½ lb. per square, that is, per 100 sq.ft. of surface, uniformly spread on one side only. In hot weather, 3½ lb. per square is permissible.

7. To determine the effect of the saturant on the burlap, for it is sometimes injurious to its tensile strength, the fabric should be tested in a tension machine; a well saturated fabric will always show an increase in strength over the raw burlap, but when tested in strips 1 in. in width, it should show not less than 80 lb.

8. A sample of the saturating flux should show on chemical analysis the following:

Solubility in carbon tetrachloride, not less than 98%.
Solubility in [illegible] not less than 66%.
Physical tests should show:
Softening point not less than 75° F.
Melting point, not less than 140° F.
Penetration, not less than 0.75 cm.
Penetration of coating, not less than 0.15 cm.
Ductility of saturant, not less than 20 cm.
Ductility of coating, not less than 3 cm. when elongated at the rate of 5 cm. per minute in water at 77° F.

9. The woodflour should be preferably a fine granular color applied as a thin, even film on one surface only, yet if sawdust is used, it should be sparsely applied.

10. When the fabric is brought on the work, it should be stored in a dry and cool place, piled no more than three or four rolls high, protected against rain and other weather conditions, as well as from injury by resting or falling weights.

It should be noted that in hot weather a saturating flux with a higher melting point should be used than that employed during the winter, but the former should not exceed 160°, and the latter should not fall below 140°; that the amount of woodflour should be reduced as the weather grows colder, and all quantities lying loose should be swept off.

An open-mesh saturated fabric is now recognized by most engineers to be superior to the saturated felt for waterproofing purposes, as it is now employed in what is known as the membrane method of waterproofing. The reason for this conclusion is found in the fact that an open-mesh fabric permits a more thorough bonding of the successive plies of fabric with the binder, and permits the escape of air from pockets formed underneath the layer of fabric on and before the application of the binder to the surface. A substitute has been suggested in the form of perforated felt, saturated in the same way as fabric. This is simply recognizing the efficacy of open-mesh fabric which is free from the disadvantages inherent in the perforated felt, viz.: distinct layers in the form of alternate strata; lack of tensile strength, lack of amalgamation of materials and a tendency to "creep," especially on vertical walls; while the fabric possesses the advantage of acting as a reinforcement and body-giver to the membrane, being more elastic and capable of yielding over a considerable area.

Tie Treating Plant, Louisville & Nashville R. R.

SYNOPSIS—A [illegible] plant of [illegible] construction, [illegible] treatment [illegible] treatment for [illegible]. [illegible] The plant [illegible]

[illegible]

... may seriously impair the economic value of treated ties.

The Louisville & Nashville R.R. has for many years been treating piles and bridge timbers by the creosoting process at its West Pascagoula plant, near Gautier, Miss., but this was largely as protection against the teredo and other destructive organisms in salt water. The railway had an ample source of supply for its ties (the standard material being white oak), but with the outlook for a decreasing supply and increasing cost of first-class untreated ties, it began to consider the possible economies due to the use of ties of inferior timber treated by preservative processes, and about a year ago it was decided to undertake the treating of ties.

The question of the location of the plant was one of the first points to be considered. For a railway obtaining all its ties from one district, a single large treating plant may be economical, but this railway obtains its ties all

along the various lines of its system and it was easily shown that one large plant would not be economical, in view of the fact that cost of transportation is a large proportion of the cost incidental to treatment. The cost of haul per tie was estimated at 4c. per 100 miles, while the cost of treatment (exclusive of chemicals) was about 5c. per tie, so that it would not pay to haul the ties much more than 150 miles. It was considered the better policy, therefore, to establish two or three plants at different points so as to economically serve the different portions of the railway system.

The first of these tie-treating plants is that now in operation at Guthrie, Ky. This place was selected as being at the intersection of two important divisions, one extending from Nashville north to Henderson (on the Ohio River) and St. Louis, and the other extending from Memphis to Louisville. Thus ties are readily received and distributed, and the plant will serve the entire northwestern portion of the system.

The special features of the plant may be noted as follows: (1) The use of two preservatives, creosote oil for ties on curves (with tie plates) and zinc-chloride for ties on tangents (without tie plates). (2) The compact arrangement of the plant, with low cost of construction and operation, and special facilities for inspection of the intricate piping systems. (3) The fireproof construction of the buildings. (4) The use of cast-iron flanged pipe for all lines handling oil or zinc. (5) The steam-heating systems for the cylinders and tanks, avoiding the use of coils and pipe joints. (6) The economy in fuel consumption, due to compact arrangement of the plant and to the use of exhaust steam for heating feed water.

The plant was put in operation in March, 1911, and is treating about 60,000 ties per month. Its total cost was about $161,000, including $15,000 for the yard. The plant was designed by the railway company's engineers, and all parts were built and furnished to specifications. The buildings were erected by contract, and the equipment was supplied by various manufacturers. The grading was done by contract, and tracklaying was done by the railway company. The design and construction were under the direction of W. H. Courtenay, Chief Engineer of the Louisville & Nashville R.R., and J. B. Lindsey, Superintendent of Timber Treating Plants; H. G. Laird is Assistant Superintendent in charge of operation.

General Plan

The plant is located near the station at Guthrie, and is served by tracks connecting with both of the intersecting divisions. It occupies a tract of about 30 acres, giving ample yard room for the storage of ties for seasoning. There is room for about 500,000 ties in the yard, which is well equipped with water mains and hydrants for fire protection. The water pressure, about 25 lb., is maintained by an elevated tank of 50,000 gal. capacity.

The soil is a stiff red clay, and the foundations simply require footings in this; no piles are used. A creek running diagonally across the site has been filled up, and its course diverted to two 20-ft. drainage ditches, paralleling the longer sides of the yard and discharging through culverts in the railway embankment at the north end. The excavated material was used to fill low places in the yard. The site has a slope toward the east, and open drains are cut across the yard to drain surface and subsurface water to the ditch on the east side.

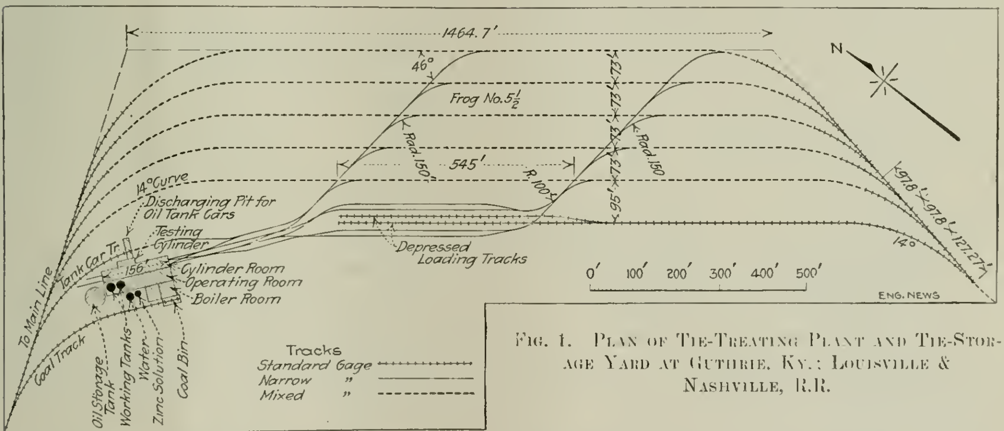

Fig. 1. Plan of Tie-Treating Plant and Tie-Storage Yard at Guthrie, Ky.; Louisville & Nashville, R.R.

The layout of the plant and yard is shown in Fig. 1. The connection at the north end is with the Louisville-Memphis main line, while that at the south end is with the St. Louis-Nashville main line. The standard-gage and mixed-gage tracks are laid with 70-lb. rails (Am. Soc. C. E. section), and the narrow-gage (30-in.) tracks with 58¼-lb. rails. The standard-gage tracks have 12-ft. switches and No. 7 frogs. There are several intersections of narrow-gage with mixed-gage tracks, and these are built of 70-lb. rails.

A locomotive is used for handling the railway coal cars, tank cars and carloads of ties, as well as for handling the tie trains on and out of the cylinders. This machine is available for general use and is considered more satisfactory and economical than a cable haulage plant for the cylinder trains. It is a four-wheeled engine, weighing 65,000 lb., and while this is not at all too powerful for the work, it represents about the maximum weight for a four-wheel engine of 30-in. gage. A six-wheel engine could not well be used on account of the sharp curves in the yard tracks. The front end of the

frame is fitted with a heavy bumper for pushing the cars. It pushes the rear end of the tie trains into the cylinder by means of a pole, so that the engine does not run onto the transfer table. It hauls the train out by a cable extending the full length of the train. A notable feature is the use of the Walschaerts valve-gear on a narrow-gage industrial locomotive of this size.

The tie cars are of structural steel, with pressed-steel ribs forming the lower part of the hoops, which hold the ties in place. They run on 12-in. wheels. Each tie train consists of 17 cars, with about 45 ties per car.

The railway cars for shipping the treated ties are placed on two standard-gage tracks, which are depressed so as to bring the car floors about level with the yard surface. This is considered preferable to running the tie cars on an elevated loading platform. This loading pit, Fig. 2, is 28 ft. wide and 4 ft. deep (to rail level). It has 6-in. reinforced-concrete walls, 7 ft. high, with counterforts 10 ft. apart and expansion joints at intervals of 55 ft.

Treating Plant

The treating plant is located at the northwest corner of the site, and has two cylinders or retorts, with provision for a third in the position now occupied by the testing cylinder. The general arrangement is shown in

Fig. 2. Section of Loading Pit

Fig. 3. The cylinders are housed in one side of a building, which contains also the boiler room, the valve or operating room and a repair shop.

The building also encloses the working tanks, but is not carried up high enough to roof over these tanks, as this would have made an expensive construction. Instead, the upper part of each tank, above the roof, is enclosed by a steel jacket, whose lower end opens into the building, while the upper end carries a hood just above the tank roof. Thus the hot air of the building passes up through the 4-in. space around the tank and roof.

The storage tanks are outside the building, but very close to it, so that the outside pipe connections are very short. These pipes are in concrete trenches, protected from the weather and readily accessible.

One of the special features of the plant, as noted above, is the use of cast-iron flanged pipe for all lines handling oil and zinc solution. This is in order to avoid the trouble of leakage at threaded joints, due to the liquid working along the threads or causing their corrosion, while the cast-iron pipe also gives better resistance to the action of the zinc and creosote. The additional cost was slight, but the pipe system had to be very carefully laid out in advance, since the parts had to be cast to specified lengths and could not be cut and adjusted like steel or wrought-iron piping. The piping is arranged with a view to accessibility and to convenient location of all valves and fittings.

The two cylinders, 7 ft. in diameter and 130 ft. long, are fitted with a single sap drum for drainage. They were shipped from the maker's shops in two lengths. Both ends have doors, but that at the south end is used as the charging door. Each of these doors is carried entirely by its two heavy hinges, no overhead or bottom support being used, and is secured by 36 hinged bolts 2¼ in. diameter. The cylinders (which are heavily lagged) rest on saddles on concrete piers 12 to 16 ft. apart. The central saddle is anchored, but the others are fitted with rollers to allow for expansion movements. In front of the two cylinders is a pit for a short transfer

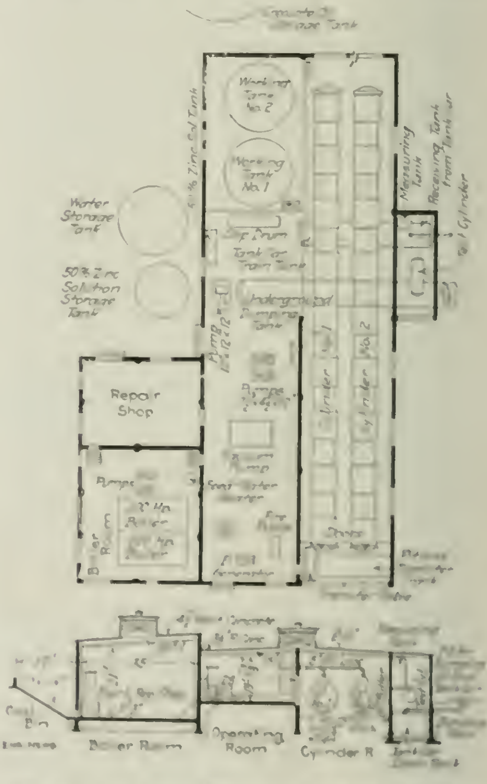

Fig. 3. Plan and Sectional Elevation of Tie Treating Plant, Louisville & Nashville R.R.

table, which connects the yard tracks with the cylinder track when the door is open. This end of the building is open, but a partition is built across it at the rear of the pit, so as to exclude cold air from the cylinder room.

The creosote oil is delivered in tank cars, and each car is spotted over a concrete pit or hopper, having an 8-in. pipe leading to a receiving cylinder in the basement. From this the oil is pumped to the storage tank. The oil for the cylinders is fed from the working tanks, and after a charge has been treated the oil is drawn off into

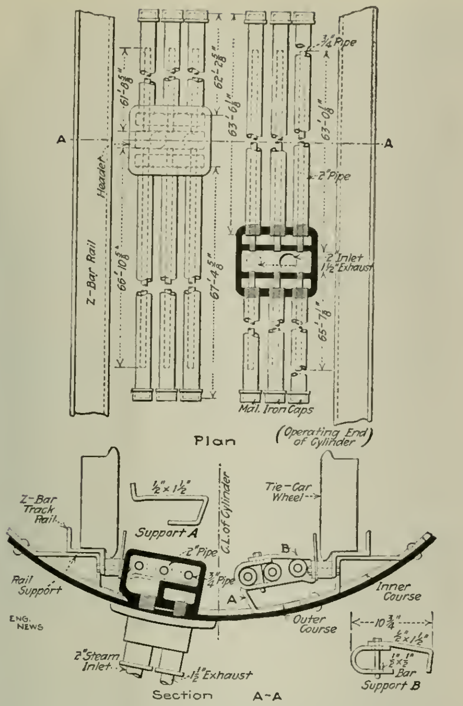

FIG. 4. TRACK AND STEAM-HEATING EQUIPMENT FOR TIE-TREATING CYLINDERS

a dumping tank in the basement, from which it is pumped to the storage or working tanks as required.

The zinc solution (50%) is also delivered in tank cars, but these have no bottom discharge. A portable pipe connection is made to the top manhole, and the solution pumped to the zinc-storage tank. The measuring of the oil and zinc solution is done by means of float gages.

For experimental work there is a cylinder 11 ft. 6½ in. x 3 ft. 7½ in., served by a measuring tank, as shown.

The heating system of the treating cylinders is of novel design, and is one of the special features of the plant. It eliminates the use of pipe coils, with the troubles incidental to keeping the joints tight, which result in oil leaking into the pipes and water getting into the oil. As shown by Fig. 4, the steam is delivered to cast-iron headers bolted to the shell of the cylinder near the bottom, and from these ¾-in. pipes extend in both directions; these pipes are inclosed in 2-in. pipes of slightly greater length, through which the steam returns to the header. The end of the larger pipe is closed with a heavy cap.

The pipes are supported and held at intervals by saddles of steel bars. The headers are placed on opposite sides of the center of the cylinder, thus leaving the bottom unobstructed for draining out the cylinder. The tie-car track in the cylinder is composed of Z-bars, with plate guard rails. The storage tanks are heated by steam pipes in the same way as described for the treating cylinders, but the larger pipes have the ends closed with heavy plugs welded to the pipe and made convex in order to resist the cutting action of the steam. Each tank has two sets of pipes, placed at right angles to each other, and attached to headers or manifolds bolted to manhole openings, as shown in Fig. 5.

The pump equipment includes the following: One duplex crank and flywheel pump, 10x16x12 in. for vacuum, one duplex piston pump 12x12x12 in. for pumping the preservative, one 7½x8½x10-in. duplex pump for pumping oil and 50% zinc solution, two 7½x4½x12-in. pressure pumps for the solution, and two boiler-feed pumps. No compressed air is used either in the treatment or for handling material. A small steam generator set supplies current for electric light in the building. On the gage board in the operating room are vacuum, steam-pressure and recording gages for each cylinder. An electric bell is rung by a float when the cylinder is full.

Steam is supplied by two horizontal water-tube boilers of 200 hp., one of these being held in reserve. A large feed-water heater is placed in the boiler room. Coal is delivered in cars which are run over a concrete trestle to a 100-ton concrete bin. This is alongside the boiler house, and the bottom slopes toward openings in the wall, so that the firemen can handle the coal direct from the bin to the boilers. Coal costs about $1 per ton. The fuel cost per tie is only about 0.18c. per tie, this very low figure being due largely to the use of exhaust steam for feed-water heating and to the compactness of the plant.

TREATMENT

The tie-treating policy on this railway is somewhat unique, in that it provides for the regular use of two

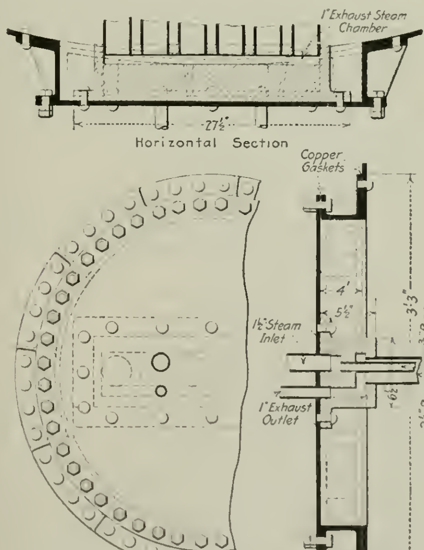

FIG. 5. STEAM-HEATING EQUIPMENT FOR OIL TANKS

distinct processes. Ties for tangents, on which no tie plates are used, will be treated by the straight zinc process. Ties for curves, all of which have tie plates, will be creosoted. The zinc process is by far the cheaper, and

a consideration of the use of creosoted ties on tangents, with metal tie plates, showed no economy over untreated white-oak ties without tie plates.

The reasons of the case may be explained as follows: For ties on tangents the cheaper zinc process will make their resistance to decay about equal to their resistance to mechanical wear. In other words, when the ties need renewal, it will be on account of both decay and wear, and they will thus have given their full service life. On curves, however, the treated ties would be worn out by the rails long before their decay, unless protected by tie plates. But with this protection the effect of the zinc preservative would have disappeared long before the tie was worn out, and in order to equalize the resistance to wear and decay under curve conditions it is economical to use the creosoting process, which is higher in first cost but gives a longer life than the zinc treatment. To apply creosoting and tie plates for all ties (on tangents as well as curves) would be too expensive under the conditions existing on this road, and advantage is taken of the economies made possible by the use of the zinc process.

The wood used is red oak, having a life of about four years untreated. The ties are 7x9 in., 8½ ft. long. The metal tie plates are 7x8½ in., ½ in. thick, with a shoulder on top and with two shallow ribs (across the tie) on the bottom. The latter are just large enough to give the plate a hold on the tie without injuring the wood.

The creosoting is done by the full-cell process, and is designed to impregnate the timber with 8 lb. of creosote oil per cu.ft. A 24-in. vacuum is obtained in about 30 min., and is then held for 2 hr.; the creosote is then admitted and a pressure of 150 lb. maintained for about 3 hr., after which 15 min. is allowed for the timber to drain, before the cylinder is opened and the charge withdrawn. The zinc process is very similar, and is designed to give ½ lb. of dry zinc per cubic foot of timber. The zinc chloride is purchased as a 50% solution, and a [illegible]% solution is used in the treatment.

The oil is required to be a coal tar creosote (free from any other oil or tar) having a specific gravity at [illegible]° C. of at least 1.0[illegible], and containing not more than 2% of water. An average of the test analyses from five tank cars show a distillate as follows:

	Per Cent.		Per Cent.
[illegible]	2.2	Total [illegible]	[illegible]
[illegible]	22.[illegible]	Residue [illegible]	[illegible]
[illegible]	[illegible]		
[illegible]	1[illegible]	Total	[illegible]
[illegible]	[illegible]		

The ties are inspected at the points of shipment by special inspectors of the Tie and Timber Department (instead of by the various roadmasters), and when stacked in the storage yard they are marked with the [illegible] and year. They are arranged in consecutive or chronological order as far as possible, thus facilitating the work and reducing the cost of yard switching in making up the cylinder trains. The ties remain in the yard for [illegible] months before treatment. The zinc-treated ties are shipped promptly after treatment, and the creosoted ties are shipped out at once, as holding them would only result in allowing some of the lighter oils to escape.

The ties for seasoning are stacked in piles of [illegible] each, with [illegible] ties at the bottom and [illegible] layers of [illegible] ties each, the adjacent layers being in contact at one end and separated at the other end (alternate ends) by a single cross-tie. This gives a comparatively low pile, with plenty of air space.

All loading, unloading and handling is done by manual labor at piece-work. There is no difficulty in getting men (colored), and they make good pay while the company gets its work done at a low rate. The average untreated tie weighs about 220 lb., and a man will readily pull out a tie, tilt it on end and so get it across his shoulder and walk off with it with little apparent effort. In handling zinc-treated ties the men sometimes wear gloves, but in general they handle the ties with bare hands and appear to suffer no discomfort from the zinc-chloride or the creosoted oil.

Records of Treated Ties

All treated ties will have dating nails, having the last two figures of the year stamped on the head. These nails will be driven in the ties when they are placed in the track, and the position of the nails in the tie will also show in what year the tie was placed, so that if the figures on the nail become obliterated the age of the tie will still be known. To determine the life of treated ties, stretches of track will be laid with 500 treated ties each. Records of the treatment of the ties in these stretches will be preserved at the tie plant, while a careful record of the location of the test tracks on the various divisions (as well as record of removals of these treated ties) will be kept by the roadmaster of each division.

Tests of Electrolysis Mitigation by the U. S. Bureau of Standards [illegible], the second of its "special studies" is reported in Bulletin 32 on tests of systems of insulated negative return feeders in St. Louis, Mo. The engineers of the Bureau secured the cooperation of the United Rys. Co. for the use of the track network supplied by the [illegible] St. substation. Eight 1,000,000-circ. mil negative-feeder lines were run in three directions, north, east and southwest, each feeder being 1[illegible] to [illegible] ft. long. They were arranged to be used, for tests, into tracks and water and gas mains as either insulated or uninsulated negative feeders according to the scheme described in "Engineering News," Feb. 26, and Apr. 2, 1914. They were designed to reduce the track potential gradient to one volt per 1000 ft. average for one-hour peak load, which would correspond to a 24-hour average of 0.[illegible] volt. Measurements were made of rail gradients, current in pipes, potential between pipes and rails, over-all potential and feeder current. Under the insulated-feeder system, but one point was found with greater than 1 volt per 1000 ft., and the 24-hour average of all was 0.[illegible] volt (corresponding to one volt at peak). Under connection as an uninsulated-feeder system, several points ran above 1 volt per 1000 ft., the 24-hour maximum being [illegible] (corresponding to [illegible] volts at peak load) and the average [illegible] (corresponding to 2 volts at peak). The current flow in gas and water pipes under the insulated-feed system, varied from 0.[illegible] to 1[illegible] amp. with a total of [illegible]; corresponding figures for same points under the insulated-feeder system were [illegible] and [illegible] amp. with a total of [illegible]. Taking in the pipe systems as feeders gave total current values of [illegible] and [illegible] amp. respectively.

The potential differences between pipes and rails, at places where, before, were above 1 volt positive, averaged [illegible] under the uninsulated and [illegible] under the insulated-feeder system. At points where the initial potential differences were below 1 volt positive, the new figures were [illegible] and 0.[illegible]. Where the initial potentials were negative there was a mean value of [illegible] volt under the uninsulated-feeder system, with the insulated feeders this became [illegible] volt positive. This is taken as showing that the extension of positive areas by the insulated negative feeders is not large enough and where it is greatly overbalanced by reduction of positive potentials, so the [illegible] diminishes more rapidly than the [illegible]. The over-all potentials on feeders between the several outlying [illegible] points and the substation were 2 volts per 1000 ft. average under the uninsulated system and 0.[illegible] insulated. The data as a whole are considered to show that under the insulated negative-feeder system currents on underground structures are so reduced as probably to cause no trouble before replacement for other reasons.

New Railway Station at Memphis

SYNOPSIS—The new Central Station at Memphis, completed in 1914, was built in connection with the Illinois Central R.R. track-elevation work, and has both stub and through tracks. The through tracks are arranged singly, the alternate platforms being for passengers and trucking, while the stub tracks are in pairs. The subways are of different types of construction to meet the conditions, and are partly of steel and partly of concrete, but all steelwork is incased with concrete. One of the retaining-walls has a 4-ft. cantilever slab for a walk overhanging the street sidewalk. The subway construction and track elevation had to be done under traffic in most cases, and the plant and methods employed are described. The headhouse includes station facilities and several floors for railway offices.

The Central Station at Memphis

The city of Memphis, Tenn., with a population of 135,000, is served by nine railway systems, the passenger traffic of which is accommodated by two new union stations, with a third station maintained under franchise conditions which require the Illinois Central R.R. to have two stations. The two union stations are about a block apart, on Calhoun St., as shown in Fig. 1. A single station was at one time proposed, but unfortunately the coöperation of all the railways concerned could not be obtained.

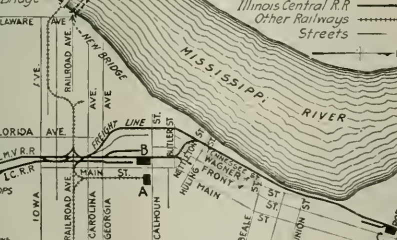

Fig. 1. Map of Central Part of Memphis, Tenn., Showing the Railways and Railway Stations

Union Station—This is owned by the Memphis Union Station Co., and was opened in 1912. It is used by the following railways: the Louisville & Nashville, the Nashville, Chattanooga & St. Louis, the St. Louis, Iron Mountain & Southern, the St. Louis Southwestern and the Southern. It is a terminal or stub-end station, with Y-approaches to a line running (east and west) at right angles to the station and leading west to the Memphis Bridge over the Mississippi River. It is shown at A in Fig. 1.

Central Station—This is owned by the Illinois Central R.R. and is a through station on its line. It is used also by the Rock Island Lines and the St. Louis & San Francisco Ry., as well as the Yazoo & Mississippi R.R. (a part of the Illinois Central System), but these make it a terminal point, and do not run further north. The station is under construction and is expected to be completed by August, 1914. It is this station, marked B in Fig. 1, which is described in the accompanying article. When opened it will have a traffic of about 46 trains daily, four of which are through trains. There are four other through trains, but these back in and pull out again at the south end of the station.

Illinois Central R.R. Improvements

The Illinois Central R.R. line entering from the north runs parallel with and west of Main St., the tracks being at the foot of a bluff along the river front and on this part of the line is the Poplar St. station C. At Beale St. the tracks leave the river bluff and run in Tennessee St. at the street level to Huling Ave., where the passenger tracks make a sharp diversion to the east by a reverse curve to the station at Calhoun and Main St., beyond which they run approximately southward. The freight tracks continue south from Huling St., running around the industrial district and connecting with the main line again at Carolina Ave. The improvements include the elevation of the former surface passenger tracks from Huling to Iowa Ave. (with a maximum elevation of 15 ft.), the removal of the tracks in Nettleton St. (on the reverse curve) to an elevated structure on private right-of-way, and the construction of a new passenger station, power house and express building.

The old line had a grade of 2.4% from Huling Ave. down to Wagner Place and then 1% into the station, which made an unfavorable condition for heavy trains pulling out to the north. The new line rises from Huling St. on a grade of 1% to the new elevation, runs through the station on grades of 0.1 to 0.3% and then falls on a 1% grade to the grade crossing of the other railways (now elevated) at Railroad Ave. Beyond this it continues practically level till it meets the old elevation south of Iowa Ave.

A direct line eliminating the reverse curve approach at the north was desirable and was considered, but the cost of property to be acquired was considered prohibitive. The north end of this curve is about 20° and the south end 15°. To reach industry tracks on Nettleton St. there is a short spur track of 4½% grade down from the new elevation at Butler St., and another with a grade of 3.8% on a 30° curve at Wagner Place. South of the station are curves connecting the main line (north and south) with the east and west main line on Railroad Ave.

The Passenger Station

The station site extends from Calhoun Ave. to Georgia Ave., along the west side of Main St., a distance of 1200 ft. It has a width of 200 ft. between the retaining-walls along Main St. and along the freighthouse driveway (which is at the street level), and this is increased to 204 ft. by a 4-ft. overhang on the Main St. side. A plan of the track layout of the station is shown in Fig. 2.

While the station is used by four lines the Illinois Central R.R. is the only one which operates its trains through the station and north of Memphis, as noted above. Consequently the track layout includes both through and stub tracks. The double-track line from the north widens into a three-track approach which again opens out into five through tracks at the station. These tracks are not in pairs (as is the more usual plan), but are spaced alternately 23 ft. and 22 ft. c. to c., with 13-ft. passenger plat-

forms and 16-ft. trucking platforms at the wider and narrower spacing, respectively. This arrangement will keep the passenger platforms free from baggage trucks.

Parallel with the through tracks there are five stub tracks entering from the south and terminating at the headhouse. These are in pairs with alternate spacing of [illegible] ft. and 21½ ft. Their platforms will be used for both passengers and trucking, but the provision of baggage elevators at both ends of the platforms will reduce to a minimum the amount of trucking along the platforms. The length of the platforms is about 800 ft. at the through tracks and 600 ft. at the stub tracks, the latter having a 50-ft. cross platform at the end of the tracks. All of the platforms will be of concrete, but the temporary wooden platforms will remain until the new fill has settled thoroughly. They are covered with steel frame canopy shelters of the butterfly type, having a wood roof.

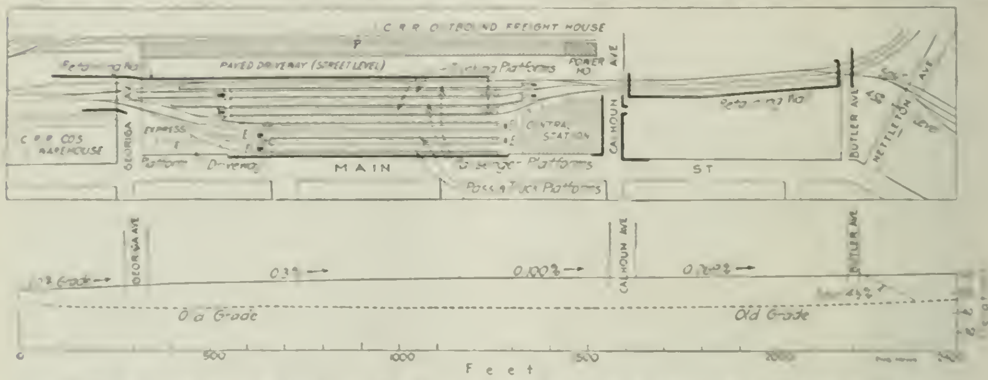

FIG. 2. PLAN OF THE NEW CENTRAL STATION AND ELEVATED APPROACHES AT MEMPHIS, TENN.; ILLINOIS CENTRAL R.R.

The canopies are 11 ft. high and about 13 ft. wide.

At the south end the ten station tracks converge into the double-track main line. The frogs throughout the terminal are Nos. 8 and 10, with No. 10 slip switches in the double crossover connections between the main tracks at each end of the station. These crossovers enable trains to be routed from either main track to any one of the station tracks. The through tracks and all turnouts are laid with 90-lb. rails in stone ballast, while 75-lb. rails are used in the elevated portions of the stub tracks.

The station building or headhouse is [illegible]×160 ft. at the street level and is eight stories high, or 100 ft. from sidewalk to roof. A rather unusual feature is that the upper portion (five stories) is smaller in plan than the lower portion, which contains the station facilities. The lower part of the building, or the station proper, is in the Roman Doric style of architecture, and built of Bedford stone. The upper part is of red brick and terra cotta. The structural frame is of steel. The street level plan is shown in Fig. 3.

The upper floors contain the railway division offices, station offices and various facilities. The Illinois Central R.R. division hospital and medical service is installed here, and a doctor will be in constant attendance for the service of employees and passengers.

In this station the street entrance is at the lower level and the track floor is at the upper level, 15 ft. above. An unusual feature has been introduced to break up the flight of stairs, and that is the location of the concourse at an intermediate elevation, as will be seen by the cross-section in Fig. 3. Passengers entering from the street will find at hand the ticket office, baggage-checking counter, parcels-checking room, restaurant and lunchroom. A short flight of steps, only 8 ft. in height, gives access to the concourse, which serves as a general waiting room. Passengers going direct to the trains will pass across this to the gates leading to the stairways which give access to the several platforms. Passengers having to wait any length of time, can ascend a short flight of steps leading from the concourse to a waiting room which is at the side of the building and retired from the concourse. In connection with this are the toilet rooms, a nursery, and rest rooms for women.

As Tennessee is one of the Southern states having laws requiring separate accommodations for whites and colored people, there are special waiting, dining, lunch and toilet rooms for colored people, and these are arranged so as to be as independent as possible, the races meeting together only at the concourse and the approaches to the trains. In addition to this, independent rooms and accommodations are provided for immigrants. A rather novel feature will be a telephone train-announcing system (to be installed later), having loud-speaking "trumpets" or announcers fitted in the concourse, waiting room, etc. A pneumatic-tube system for messages will afford means of communication between the several offices and departments.

From the baggage room a rectangular concrete subway or tunnel extends southward through the station fill for nearly 700 ft., and connects with cross tunnels to the elevators at the south end of the platforms. This subway extends also to the express buildings at the southeast corner of the station. It has walls of concrete, heavily reinforced with steel, and a waterproofing compound was added with the water. The floor is finished with "granitic" to render it both hard and waterproof.

TRACK ELEVATION AND SUBWAYS

The track elevation eliminates the former six grade crossings at Carolina, Calhoun, Butler, Front, Wagner and Nettleton Aves., all of which streets carry heavy hauling traffic for warehouses and industries. At most of these crossings there was little change in the street

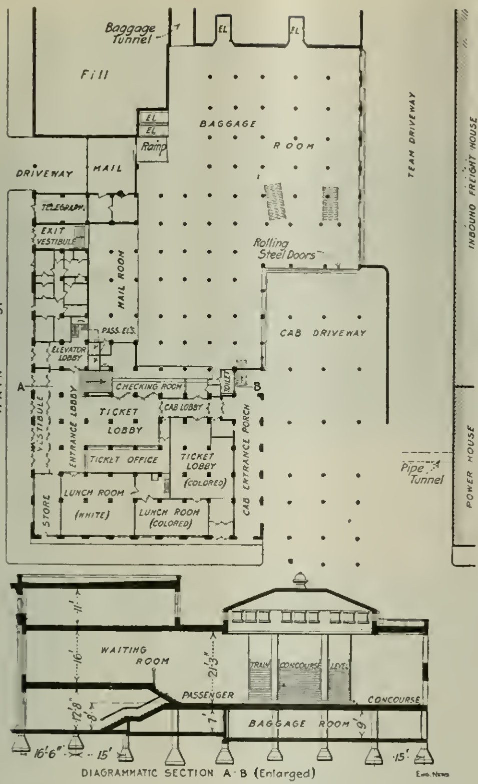

FIG. 3. PLAN AND CROSS-SECTION OF STATION BUILDING

grades, but Carolina Ave. was lowered considerably in order to give the required 12-ft. headway, as the elevation of the tracks here was governed by the approach to the railway grade crossing at Railroad Ave. The street approaches in this case are 4% at one end and 2.85% at the other. Both gravity and reinforced-concrete retaining-walls are used in different parts of the work, and all steelwork of the subways is incased in concrete.

The Carolina Ave. subway, Fig. 4, is 65 ft. wide between the abutments, and is 215 ft. long, carrying ten tracks. It has heavy gravity abutments at the street lines, and three intermediate supports or bents, spaced 23 ft. 9 in. c. to c. These intermediate supports consist of heavily reinforced footings, 18-in. circular columns (with spiral reinforcement), and a top or cap girder with semicircular arches between the columns, which are spaced 6 ft. c. to c. The deck is made of reinforced-concrete slabs, cast in a temporary yard and set in place by a wrecking crane.

At the ends of the subway, the grades of the approach and the tracks made a shallower floor necessary. For the two tracks at the east end, there are three lines of 36-in. plate-girders (parallel with the tracks) having 12-in. I-beams across the lower flanges and a solid concrete filling between and over the I-beams and incasing the girders, as shown in Figs. 4 and 6. The deck is 19 in. thick at the middle and 15 in. at the abutment ends, covered with a 2-in. waterproofing course. For one track at the west end the deck is of longitudinal I-beams embedded in concrete. The concrete is 1½ in. thick beneath the I-beams and there is a sheet of expanded metal beneath the beams and embedded in the concrete. The exposed surfaces of the concrete, facing the street, are 40 in. deep and are relieved by panels recessed 2 in.

The Calhoun Ave. subway, in front of the station has two roadway spans 24 ft. 3 in. c. to c. of columns, a sidewalk span of 15 ft. 3 in. on the station side, and a similar span of 10 ft. 9 in. on the opposite side. It carries three tracks (14 ft. c. to c.) and is 44 ft. 2 in. long over all, with 14-ft. headway for the street spans, as there is an electric railway on this street. The three bents have steel columns supporting box girders parallel with the street line, all the steelwork being incased with concrete.

Longitudinal I-beams are framed between the webs of the box girders, the tops of the beams and girders being at approximately the same level, and the I-beams being embedded in a concrete deck which is 30 in. thick in the roadway spans. The concrete is shaped at the sides to form 18-in. curb walls (with iron railings), and the exposed faces represent fascia girders with paneled faces. For 300 ft. south of this subway, which is the space occupied by the baggage room and the cab and baggage driveway, there are steel columns incased in concrete and carrying a steel floor framing of girders and stringers, with a 6-in. deck slab reinforced with wire mesh.

The Front St. subway, Fig. 5, is 60 ft. between abutments. It is similar to the one at Carolina Ave., except that the floor over the roadway is of longitudinal I-beams (embedded in concrete) resting on the reinforced-con-

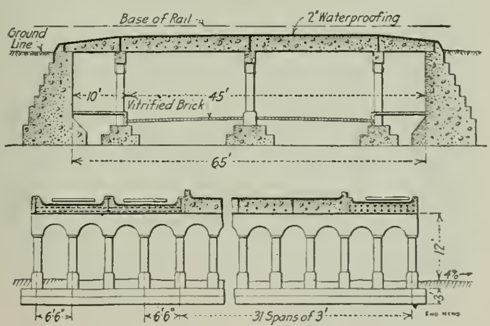

FIG. 4. THE CAROLINA AVE. SUBWAY AT MEMPHIS, TENN.; ILLINOIS CENTRAL R.R.

(Note the three different types of construction shown in the cross-section.)

crete bents, while concrete slabs form the sidewalk spans. The Butler Ave. subway (only 30 ft. between abutments) has gravity concrete abutments with a single 30-ft. span of the I-beam and concrete deck. This same construction, with 20-ft. span, is used at Wagner Place, where it forms a part of the skew bridge across Nettleton Ave.

The Nettleton Ave. subway is a complicated structure, due to its skew location (at an angle of about 30° with the center line of the street), the sharp curve of the tracks, and the fact that it extends across the intersection of Wagner Place. In this case the intermediate bents have columns 17 ft. c. to c. carrying heavy steel girders embedded in concrete. Upon these and the abutments are

[illegible] girders for the [illegible] ballast, and the I-beams of the floor rest upon the lower flanges of these girders. These I-beams are placed at right angles to the street line, so that, owing to the skew, many of them have one end carried by the lower flange of the main girder and [illegible] projection overhanging the sidewalk and carried by cantilever brackets, as shown in Fig. 7. The wall was built in sections 40 ft. long. No expansion filling was placed at the joints, but tarred paper and burlap were laid behind them to prevent leakage of water in the fill.

FIG. 5. CONCRETE ABUTMENTS AND BENTS FOR THE SOUTH FRONT ST. SUBWAY

[illegible] and resting on the abutment or on the top of the cross-girder of the intermediate bent.

All the steelwork in the structure is wrapped with wire mesh and [illegible] in concrete. The street faces of the girders are [illegible], and are rubbed down with carborundum blocks to remove form marks. The decks are formed with curb walls to retain the ballast, and upon these are erected iron railings. The standards for these railings are set in cast-iron bases so shaped that the sockets for the posts are over the inner line of the parapet, thus giving the maximum clearance between cars and railings.

The decks of the subways have a waterproofing course of [illegible] felt and [illegible] pitch [illegible] with $1\frac{1}{2}$ in. of [illegible] and sand, making a total thickness of nearly 2 in. This is turned up against the sides, where it is protected with a concrete [illegible]. The construction is shown in Fig. 6, which represents the girder span of the Carolina Ave. subway. The [illegible] of the retaining-walls and platform-

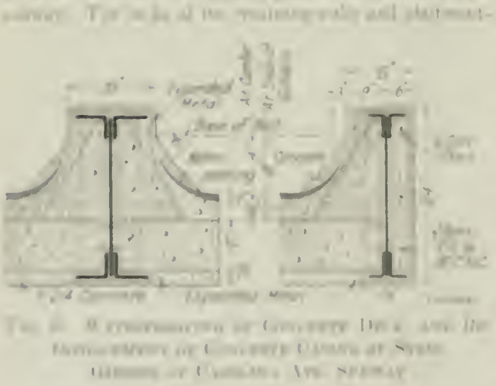

FIG. 6. WATERPROOFING OF CONCRETE DECK AND [illegible] OF CONCRETE [illegible] AT [illegible] GIRDERS OF CAROLINA AVE. SUBWAY

[illegible] coated with a bituminous preparation. Nearly all this waterproofing work was done by the railway company.

The fill at the station site, between Carolina and [illegible] Aves., has a retaining-wall on either side. On the east, or [illegible] side, this is a [illegible] wall 18 ft. high, with counterforts. At the top this has a [illegible]

On the west side is a heavy gravity retaining-wall along the driveway of the freighthouse (at the street level). This is shown in Fig. 8, which shows also the temporary track left in the driveway (but now removed) and the temporary platforms for the first tracks on the new elevation. The elevator tower beyond the platform shelter indicates the position of the station building. Similar walls (but without the cantilever slab on the reinforced walls) are used at other streets. Near the [illegible] Ave. subway the retaining-wall is surmounted by an open-work parapet wall, having concrete panels cast separately and set in place.

The construction of the retaining-walls and subway [illegible]

CONSTRUCTION WORK

The construction of the retaining-walls and subway bridges was hampered by the necessity of providing for traffic. There were about [illegible] trains daily, the heaviest traffic being from 7 a.m. to noon, and 5 to 6 p.m. The only freight movements over this part of the line were in [illegible] service. The great difficulties encountered were the limited space available, the handling of concrete while keeping clear of trains, and the inability of the contractors to get certain parts of the site delivered to them for work at the time desired. For all the work (except at Carolina Ave.) the storage space for materials was very limited, and it was necessary to regulate shipments of all kinds so as to be able to use the material upon arrival.

The concrete was delivered in place by spouting from elevator towers, using self-supporting trussed chutes. Two stationary plants with [illegible] towers and one portable plant with a [illegible] tower were used, each of the former being set up twice (in different locations) and the latter being shifted as required. Each had its mixer, and in order to work to full capacity a two-compartment material bin or hopper was erected over the mixer, holding about [illegible] cu.yd. of stone and 15 cu.yd. of sand. The materials were brought in railway cars and unloaded direct to the mixer bin or to small storage piles, there being little room for storage. A derrick with clamshell bucket took the material from the car or storage pile and dumped it into [illegible] cars which were hauled up a cable incline and dumped into the material hopper. The in-

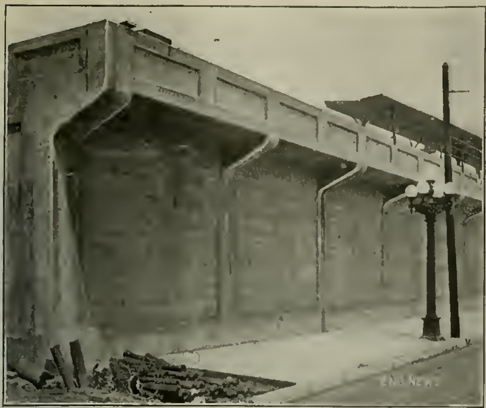

FIG. 7. REINFORCED-CONCRETE RETAINING WALL (COUNTERFORT TYPE) WITH CANTILEVER SLAB FOR WALK

(Main St. side of new Central Station at Memphis, Tenn., Illinois Central R.R.)

located in the freighthouse driveway at Calhoun Ave., was kept open until Apr. 24, when it was put on the elevation. At the station this ran through the freighthouse driveway, at the foot of the retaining-wall on the west side of the station (Fig. 8). A temporary ticket office and other facilities were maintained at Calhoun St.

ENGINEERS AND CONTRACTORS

The design and construction of the whole work was under the direction of A. S. Baldwin, Chief Engineer of the Illinois Central R.R., and F. L. Thompson, Assistant Chief Engineer (then Engineer of Bridges and Buildings). F. R. Judd was assistant engineer in charge.

The retaining-walls and subways were built by the Bates & Rogers Construction Co., of Chicago, whose superintendent was R. Rasmussen. The station building was erected by the James Alexander Construction Co., of Memphis. All steelwork supporting the tracks and for the platform shelters and express building was erected by the Strobel Steel Construction Co., of Chicago. The power house, express building and the roofs of the platform shelters were built by Geo. B. Swift & Co., also of Chicago. The filling and track work, also the waterproofing of bridge floors, was all done by the railway

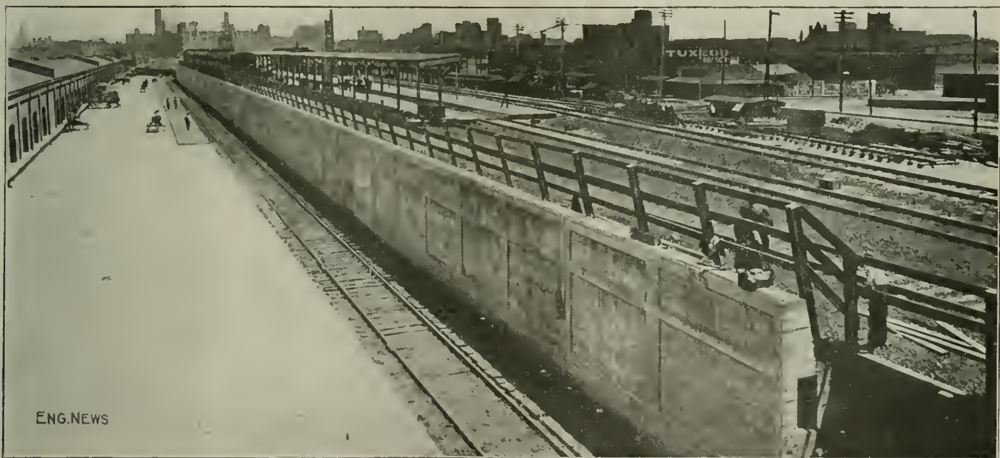

FIG. 8. CONCRETE RETAINING WALL (GRAVITY TYPE) AT THE NEW CENTRAL STATION AT MEMPHIS, TENN.

(At the left are the freight house and team driveway. The old running track at street level has now been removed. It was used during the elevation of the tracks.)

cline had a four-rail track in the lower portion and a three-rail track at the top.

Steel forms were used for the subway columns and arches. The concrete was made with stone and river sand. The proportions were 1 : 3 : 6 for gravity concrete, 1 : 2 : 4 for reinforced concrete and 1 : 1½ : 3 for the ornamental parapet panels, the 18-in. columns and the casing of steel girders.

The maximum output per day was about 550 yd. The entire elevation work, covering a distance of about 3000 ft., included about 30,000 yd. of concrete, 500 tons of reinforcing steel and 50,000 yd. of excavation. The crew varied from 100 to 600 men, depending upon the work that could be given to the contractors and the railway forces at one time.

One running track of the old line at street level, and

company. The architects for the station were D. H. Burnham & Co., of Chicago, who made the design to conform to general plans and requirements submitted by the railway company.

Is Public Office a Public Trust or a Private Snap?—The modern tendency among men who are trying to promote efficiency in the public service is to get the best man for the job—at home, if possible, otherwise abroad. And in every city where the new idea has taken hold there is the same shout to "keep the jobs at home."

It all depends upon the point of view. If the municipality is more interested in providing jobs for its home people than in developing efficient government, of course the proposition to hire out-of-town experts is wholly unjustifiable. But if efficient and satisfactory service is to be taken as the chief end of municipal government, it is quite obvious that when the right kind of a man is not available at home, he should be looked for wherever he is to be found—Cincinnati "Times-Star."

Reinforced-Concrete Flat-Slab Floors; New Chicago Building Ordinance

By J. Norman Jensen*

On Aug. 18, the Commissioner of Buildings of Chicago signed a ruling on the design and testing of reinforced-concrete flat-slab or girderless floor systems which is the result of nearly four years' study and testing. In the complication of methods of design prevalent for such systems, this one should prove both rational and simple.

In the early part of 1911, the necessity for a careful analysis and rational method of design of the flat-slab type of reinforced-concrete construction was felt in the Building Department. Plans showing the details of this recent advance in building construction were submitted to the department for approval, and it was desirable to have more information on the subject. In June, 1911, the Cantilever Flat Slab System controlled by the Concrete Steel Products Co., of Chicago, applied for a permit to use their type of construction. The Commissioner of Buildings, Henry Ericsson, appointed a commission of three engineers to investigate this system, and make a report recommending rational methods of design. This was the first flat-slab investigated.

From time to time other systems of flat-slab construction were reported on in the same way. In each case the report was made by a commission appointed as in the first case. The personnel was not always the same, but the greater proportion of the reports submitted bore the names of Prof. A. N. Talbot, of the University of Illinois, Prof. W. K. Hatt, of Purdue University, and Ernest McCullough, consulting engineer of Chicago.

Sources of Information

It is impossible to enumerate all the sources of information which were drawn upon in these reports, but a few typical ones will illustrate the thoroughness of these investigations. Whatever information obtained in the tests on reinforced-concrete footings made in the Engineering Experiment Station of the University of Illinois, which would have any bearing on the subject, was used. In some respects, the flat slab may be considered an inverted footing. The rubber panel tests conducted by the Corrugated Bar Co., and their extensometer tests in Minneapolis, Detroit, Niagara Falls and other cities were [illegible]. Theoretical analyses based on assumptions which appeared to be sound were also used insofar as they seemed applicable. The great source of information was [illegible] tests on full size structures, such as the tests which were conducted on the Deere & Webber building in Minneapolis, the [illegible] Printing Co., A. J. [illegible], Larkin, Schulz Baking Co., and other buildings in Chicago and elsewhere. [illegible]

By the middle of 1914, a great mass of information had accumulated in the office of the Chicago Building Department. Various tests had brought out certain facts which were not contemplated in the earlier reports. Using the accepted reports as a basis the department drew up a ruling in the following form:

THE DESIGN OF FLAT SLABS SHALL BE IN ACCORDANCE WITH THE FOLLOWING RULING

Definitions—Flat-slabs as understood by this ruling are reinforced-concrete slabs supported directly on reinforced-concrete columns with or without plates or capitals at the top, the whole construction being hingeless and monolithic without any visible beams or girders. The construction may be such as to admit the use of hollow panels in the ceiling or smooth ceiling with depressed panels in the floor.

The column capital shall be defined as the gradual flaring out of the top of the column without any marked offset.

The drop panel shall be defined as a square or rectangular depression around the column capital extending below the slab adjacent to it.

The panel length shall be defined as the distance center to center of columns of the side of a square panel, or the average distance center to center of columns of the long and short sides of a rectangular panel.

Columns—The least dimension of any concrete column shall be not less than one-twelfth the panel length, or one-twelfth the clear height of the column.

Slab Thickness—The minimum total thickness of the slab in inches shall be determined by the formula.

$$t = 0.[illegible] L \sqrt{w}$$

In the formula hereinabove given,

t = Total thickness of slab in [illegible]

L = Panel length in ft.,

w = Total live and dead load in lb. per sq. ft.

In no case shall the slab thickness be less than one-thirty-second of the panel length for floors, and one-fortieth of the panel length for roofs, and also not less than 6 in.

Column Capital—The diameter of the column capital shall be measured where its vertical thickness is at least $1\frac{1}{2}$ in. and shall be at least 0.22[illegible] of the panel length.

The slope of the column capital shall nowhere make an angle with the vertical of more than 45°. Special attention shall be given to the design of the column capital in considering eccentric loads, and the effect of wind upon the structure.

Drop Panel—The depth of the drop panel shall be determined by computing it as a beam, using the negative bending moment specified elsewhere in this ruling. The width and length shall be determined by the allowable unit shearing stresses on the perimeter given below.

Shearing Stresses—The allowable unit punching shear on the perimeter of the column capital shall be three-fiftieths of the ultimate compressive strength of the concrete as given in section [illegible] of the building ordinance. The allowable unit shear on the perimeter of the drop panel shall be [illegible] of the ultimate compressive strength of the concrete. In computing shearing stress for the purpose of determining the resistance to diagonal tension, the method specified by the ordinance shall be used.

Panel Strips—For purposes of establishing the bending moments and the resisting moments of a square panel, the panel shall be divided into strips known as strip A and strip B. Strip A shall include the reinforcement and slab in a width extending from the center line of the columns for a distance each side of this center line equal to one-quarter of the panel length. Strip B shall include the reinforcement and slab in the half width remaining in the center of the panel. At right angles to these strips, the panel shall be divided into similar strips A and B having the same widths and reference to the center line of the columns as the above strips. These strips shall be for designating purposes only, and are not intended as [illegible].

[illegible]

Bending Moment Coefficients, Interior Panel, Two-Way System—The negative bending moment taken at a cross-section of slab strip A at the edge of a column capital [illegible] shall be taken as [illegible]. The positive bending moment [illegible] strip A [illegible] shall be taken as [illegible]. The positive bending [illegible]

*Architectural Engineer, Department of Buildings, Chicago, Ill.

moment taken at a cross-section of each strip B in the middle of the panel shall be taken at $WL^2/60$. The negative bending moment taken at a cross-section of each strip B on the center line of the column shall be taken at $WL^2/60$. In the formulas hereinabove given

W = Total live and dead load per lin.ft. of each strip,
L = Panel length in ft.

Bending Moment Coefficients, Interior Panel, Four-Way System—The negative bending moment taken at a cross-section of each strip A at the edge of the column capital or over it, shall be taken as $WL^2/15$. The positive bending moment taken at a cross-section of each strip A, midway between column centers shall be taken as $WL^2/40$. The positive bending moment taken at a cross-section of each strip B in the middle of the panel shall be taken at $WL^2/60$. The negative bending moment taken at a cross-section of each strip B on the center line of the column shall be taken at $WL^2/60$.

Bending Moment Coefficients, Wall Panels—Wherever the coefficients $^1/_{15}$, $^1/_{30}$, $^1/_{40}$ or $^1/_{60}$ appear in the moments given for interior panels in either the two-way or the four-way systems, the coefficients $^1/_{12}$, $^1/_{25}$, $^1/_{33}$ and $^1/_{50}$, respectively, shall be used in the moments for wall panels supported on concrete columns and girders.

When brick walls are used to partly support wall panels, these walls shall be stiffened by pilasters or piers as directed by the Commissioner of Buildings. Wherever the coefficients $^1/_{15}$, $^1/_{30}$, $^1/_{10}$ or $^1/_{60}$ appear in the moments given for interior panels in either the two-way or the four-way systems, the coefficients $^1/_{10}$, $^1/_{20}$, $^1/_{27}$ and $^1/_{40}$, respectively, shall be used in the moments for such panels resting on brick walls.

Point of Inflection—For the purpose of making the calculations of the bending moment at the sections away from the column capital, the point of inflection shall be considered as being one-quarter the distance center to center of columns, both crosswise and diagonally, from the center of the column.

The Tensile Stress in Steel and Compressive Stress in Concrete—The tensile stress in steel and the compressive stress in the concrete to resist the bending moment shall be calculated on the basis of the reinforcement and slab in the width included in a given strip, and according to the assumptions and requirements given in sections 545 to 548, inclusive, of the building ordinance.*

The steel shall be considered as being concentrated at the center of gravity of all the bands of steel in a given strip.

For the four-way system of reinforcement, the amount of steel to resist the negative bending moment over the support in each strip A shall be taken as the sum of the areas of steel in one cross band and one diagonal band. The amount of steel to resist the positive bending moment of each strip B shall be considered as the area of the steel in a diagonal band. The amount of steel to resist the positive bending moment in each strip A shall be considered as the area of the steel in a crossband, and the amount of steel to resist the negative moment in each strip B shall be the steel included in the width of strip B.

For the two-way system of reinforcement, the amount of steel to resist the bending moment in any stirp that shall be considered as the area of steel included in the width of the strip.

In both systems of reinforcement the compressive stress in the concrete in any strip shall be calculated by taking the area of steel considered for each strip and applying it in a beam formula based on the principles of Sect. 548 of the building ordinance.

Rectangular Panels—When the length of a panel does not exceed the breadth by more than 5%, all computations shall be made on the basis of a square with sides equal to the mean of the length and breadth. In no rectangular panel shall the length exceed four-thirds the breadth.

For panels with length more than 5% in excess of the breadth, the slab shall first be designated for a bending moment based on an assumed square panel with sides equal to the mean of the length and breadth of the rectangular panel.

For the four-way system of reinforcement, the amount of steel found for the positive moment of each strip B by designing in this manner shall be that used in the diagonal band. For the positive moment in each strip A, the required amount of steel in the crossband shall be obtained by multiplying the steel used in the design of the assumed square panel by the cube of the ratio found by dividing the length or breadth of the rectangular panel by the side of the assumed square panel, for the long and short sides of the panel, respectively. The compressive stresses shall be calculated on the basis of a width equal to one-half of the side of the assumed square panel, and on the assumptions used in the calculations of compressive stresses in square panels. In no case shall the amount of steel in the short side be less than two-thirds of that required for the long side.

For the two-way system of reinforcement, the amount of steel found for the positive and negative moment of each strip B by designing in this manner shall be obtained by multiplying the steel used in the design of the assumed square panel by the cube of the ratio found by dividing the length or breadth of the rectangular panel by the side of the assumed square panel, for the short and long sides of the panel, respectively. The method of obtaining the amount of steel required for each strip A shall be the same as that given above for the four-way system.

Walls and Openings—Girders or beams shall be constructed under walls and around openings, and to carry concentrated loads.

Computations—Complete computations of interior and wall panels and such other portions of the building as may be required by the Commissioners of Buildings shall be left in the office of the Commissioner of Buildings when plans are presented for approval.

Placing of Steel—In order that the slab bars shall be maintained in the position shown in the design during the work of pouring the slab, spacers and supports shall be provided satisfactory to the Commissioner of Buildings. All bars shall be secured in place at intersections by wire or other metal fastenings. In no case shall the spacing of the bars exceed 9 in. The steel to resist the negative moment in each strip B shall extend one-quarter of the panel length beyond the center line of the columns in both directions.

All splices in bars shall be made over the column head. The length of the splice beyond the center line of the column in both directions shall be at least 2 ft., nor less than that necessary for the full development of the strength of the bar as limited by the unit bond stresses given by the ordinance. The splicing of adjacent bars shall be avoided as far as possible.

Slab bars which are lapped over the column, the sectional area of both being included in the calculations for negative moment, shall extend not less than 0.25 of the panel length for crossbands, and 0.35 of the panel length for diagonal bands, beyond the column center.

Test of Workmanship—The Commissioner of Buildings or his representative may choose any two adjacent panels in the building for the purpose of ascertaining the character of workmanship. The test shall not be made sooner than the time required for the cement to set thoroughly, nor less than six weeks after the concrete had been poured.

All deflections under test load shall be taken at the center of the slab, and shall be measured from the normal unloaded position of the slab. The two panels selected shall be uniformly loaded over their entire area with a load equal to the dead load plus twice the live load, thus obtaining twice the total design load. The load shall remain in place not less than 24 hr. If the total deflection in the center of the panel under the test load does not exceed 1/[illegible] of the panel length, the slab may be placarded to carry the full design live load If it exceeds this amount of deflection, and recovers not less

---

*Footnote herewith gives unit stresses allowable.

546. **Ratio of Moduli of Elasticity—Adhesion—Bond.** (a) The calculations for the strength of reinforced concrete shall be based on the assumed ultimate compressive strength per square inch designated by the letter "U" given in the table below for the mixture to be used.

(b) The ratio designated by the letter "R" of the modulus of elasticity of steel to that of the different grades of concrete shall be taken in accordance with the following table:

	U	R
1 cement, 1 sand, 2 broken stone, gravel or slag..	2900	10
1 cement, 1½ sand, 3 broken stone, gravel or slag	2400	12
1 cement, 2 sand, 4 broken stone, gravel or slag..	2000	15

547. **Unit Stresses for Steel and Concrete.** (a) The stresses in the concrete and the steel shall not exceed the following limits:

(b) Tensile stress in steel shall not exceed one-third of its elastic limits and shall not exceed 18,000 lb. per sq.in.

(e) Direct compression in concrete shall be one-fifth of its ultimate strength. Bending in extreme fiber of concrete shall be 0.35 of the ultimate strength.

(f) Tension in concrete on diagonal plane shall be one-fiftieth of the ultimate compressive strength.

(g) For a concrete composed of one part of cement, two parts of sand and four parts of broken stone, the allowable unit stress for adhesion per square inch of surface of imbedment shall not exceed the following:

	Pounds per sq.in.
On plain round or square bars of structural steel......	70
On plain round or square bars of high-carbon steel...	50
On plain flat bars, in which the ratio of the sides is not more than 2 to 1......................................	50
On twisted bars when the twisting is not less than one complete twist in eight diameters................. ..	100

than 80% of the total deflection within seven days after the load is removed the slab may be placarded to carry the full design live load. If the deflection exceeds the allowable amount above specified, and the recovery is less than 80% in seven days after the removal of the test load, other tests shall be made on the same or other panels, the results of which will determine the amount of live load the slabs will be permitted to carry.

General—The design and execution of the work shall conform to the provisions of the Chicago building ordinances and to correct principles of construction.

Discussion of Ruling

Certain phases of this ruling may require further explanation. Fig. 1 shows a plan and section of a typical interior panel contemplated in the ruling. The general arrangement of steel is not shown, as it varies somewhat with the ideas of the designers. As a rule, the reinforcement consists of belts of steel placed on rectangular and diagonal lines with respect to the center line of the column. In the middle of the panel, the steel is in the bottom. Over the column heads and at right angles to the rectangular bands, most of the steel is in the top of the slab.

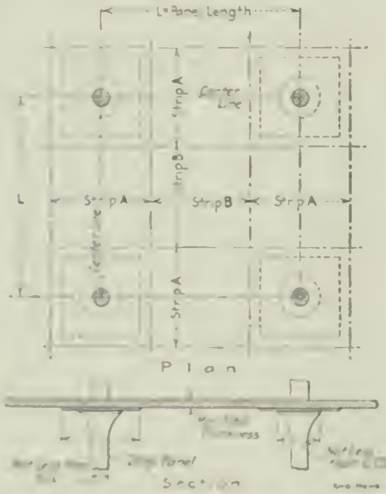

Fig. 1. Typical Flat-Slab Floor as Described in New Chicago Building Ruling

As a preliminary step, it was necessary to define the terms used. The first step was the determination of the minimum width of the column. Test after test has shown that the column head, and that the stresses on the extreme fiber of the column may be even greater than in the slab itself. So it is that the column is an essential part of the whole construction, and they should not be [illegible] in any flat-slab design.

The thickness of the slab has been a much discussed point. This thickness should be a function of both the span and the load, so the formula given was adopted. The formula controls for heavy loads, and the other requirements for light loads.

The minimum diameter of the column capital is given because the capital performs a valuable function in stiffening the entire construction, and also because the bending moments given were based on such a width. The function of the drop panel is to provide a greater depth for negative moment for the slab, and also to provide additional concrete for shear.

Referring to Fig. 1, it will be seen that the slab is divided into imaginary strips *A* and *B* as defined in the ruling. In any slab, the bending moment varies from point to point, being least in the middle and increasing as the center line of the columns is approached. To be strictly correct, therefore, the slab should be divided into a great many strips so that the values for these varying moments could be expressed. For practical reasons, the slab was divided into the two strips shown.

Although the spacing of the steel may vary within the width of the strip to resist the varying bending moment, still these strips are a convenient way of expressing the bending moment for the full width of the strip. The product WL, appearing in the formulas used for each strip, is really one-half the total load on the whole panel measuring center to center of columns, as it will be seen by inspection of Fig. 1 that $W = wL/2$, where w is the total live- and dead-load in lb. per sq.ft.

The bending moment for the middle of the panel seems very small. When one considers that the flat slab is essentially a cantilever, the moment does not seem so strange. It will also be noticed that the same bending moment is given for the strip at right angles to strip *A* on the center line of the columns. The cracking in the top of the slab and various tests have shown that tensile stresses exist in this part of the slab, and for that reason a small amount of steel is required to take care of these stresses.

For the same span and load more steel or concrete or both are required in wall panels than in interior panels. The coefficients for panels supported on brick walls are given in the ruling. The reason for the larger moments for the latter support is the fact that a brick wall is a poor type of construction to take the bending that usually exists in columns carrying flat slabs. The results of some flat-slab jobs resting on brick walls are not as satisfactory as they might have been.

The subject of the point of inflection has been an open argument for some time. The results of tests are not entirely concordant, but the method used represents good practice.

As far as the ruling is concerned, the flat slab is a beam, and nothing else. Knowing the moments and loads, the design resolves itself into ordinary reinforced-concrete design. The tensile stress in the steel and the compressive stress in the concrete can be computed on that basis.

The distribution of load in rectangular panels is given by some authorities as a function of the fourth power of the span, and by others as a function of the cube. The method of the values given by the ruling represents the present knowledge on this subject.

No matter how carefully a slab is designed, if no provision is made to keep the steel in the position where it belongs, the design is valueless. There are a great many ways of accomplishing this purpose, but especial attention must be paid to the steel over the column capital.

While the ruling states that splices should be made over the column head, still all the laps should not be in a line. Such an arrangement would create a plane of weakness, and for this reason it is advisable to distribute the laps so as to occur at different column capitals.

After the work is up it is required to be tested. The

deflection is used as a measure of the workmanship. It has been found by experience that the deflection requirement as given is not excessive, as any well designed and carefully built job will test to comply with this portion of the ruling, if the concrete has had a sufficient time to set.

All buildings used for the manufacture and storage of goods in the City of Chicago are required to be placarded. Each floor of each such building is required to have a card on which is stated the safe live-load per square foot to which the floor can be loaded. These cards are prepared by engineers and architects, and if correct, are

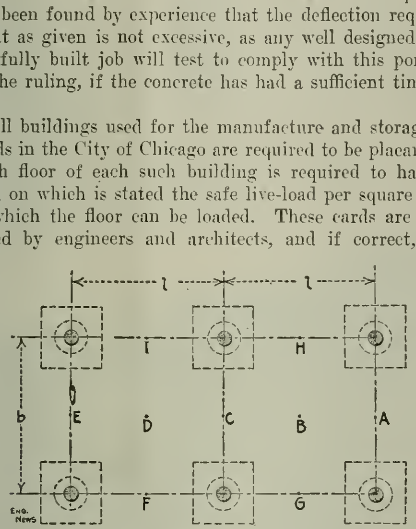

Fig. 2. Diagram Showing Location of Deflection Measurements in Chicago Building Tests of Flat-Slab Floors

approved with the official stamp of the Commissioner of Buildings. In case the design is correct, but the workmanship poor, the department has a means of preventing the loading of the floor to its full designed capacity.

Results of Tests

No matter how carefully a ruling may be drawn up, verification of such a ruling is desirable. During the last three years, 60 buildings designed in general in accordance with the ruling given above have been built. None of the buildings were more than six stories in height, but some of them covered great areas of ground.

In the accompanying table is given the results of the tests of ten buildings taken at random from the records of the department. None of these are extensometer tests. On the left-hand side of the table is given general data in regard to the panel. The total thickness of slab refers to the thickness in the middle of the panel. The designing and tests loads are given in lb. per sq.ft.

The location of the points used in measuring the deflection is given in Fig. 2. This same general method of lettering the points was maintained throughout. On the right of the table is given the total deflections of these points in $^1/_{100}$ in.

The readings of deflection were taken with great care. In some cases light poles were hung from the ceiling of the panels tested from the points shown. On these poles were glued paper targets, which were read with an engineer's level. In such cases, readings were also taken on fixed points on the columns, as there was usually a small settlement in these columns when under load. The readings thus obtained were corrected for the settlement, the corrected readings being the ones appearing in the table. Sometimes other methods were used such as fixing points in the floor and the ceiling, and reading the distances between these points with great precision. Multiplying levers were occasionally used.

It will be observed that the table covers a wide range, the test load varying from about 400 to 800 lb., and the span from 15 to 28 ft. Inspection of this table shows in some cases that points under identical conditions had the same deflection while in other cases there was a wide discrepancy. As a general rule, there was a very close agreement between the deflections of the center of the two adjoining panels.

Tests No. 4 and 5 bring out the fact that the deflection is a function of the age of the concrete. In these two buildings the conditions were identical in that the size of the panel, design, method of reinforcement, supervision and contractors were the same in both. The last two tests were on single panels as the size of the panels and the tests loads were so large that a double-panel test was waived. All the ten tests complied with the test of workmanship given above.

The statement is sometimes made that under continuous load a flat-slab panel would become fatigued, and ultimately break down. In order to determine whether there is any changes in stress or not, the department has required that a panel be tested with the test load continuously for one year. This extensometer test is under the direction of A. R. Lord, consulting engineer of Chicago, who has taken preliminary readings, and will take readings at regular intervals throughout the year.

Conclusion

The ruling as given above may not be theoretically correct according to the conception of some. It may be decidedly empirical. Information obtained in the future may necessitate a revision in some parts of the ruling. With the information available to date, however, it is known that designs prepared in accordance with this ruling will be safe, and that buildings constructed in accordance with the design in a workmanlike manner will abundantly carry the loads for which they were designed.

The Production of Natural Gas in the United States in 1913 surpassed that of any previous year in both quantity and value. Total gas production in 1913 is estimated at 581,898,239,000 cu.ft., valued at $87,847,000, an average price of 15.10c. per M. cu.ft., an increase of 19,797,787,000 cu.ft. and $3,282,720 in value over 1912. Of this total product, about 32% was utilized for domestic and 68% was utilized for industrial purposes.

West Virginia led in 1913 in quantity produced. Pennsylvania was second. Pennsylvania led in quantity consumed, and Ohio was second.—U. S. Geological Survey.

Winter Construction of a Reinforced-Concrete Building

It is not so long since contractors hesitated to undertake extensive reinforced-concrete construction in the low temperatures of winter because of the fear that the concrete could not be sufficiently protected against freezing. Under the most modern conditions of construction, however, and with proper precautions, it is now quite possible to build concrete buildings in the winter time [illegible] as in the summer. Such a construction was completed during the past winter in the erection of the concrete factory building for the New York Consolidated Card Co., at 12th St. and Webster Ave., Long Island City, in the City of New York.

This building is five stories high and covers in plan an area of [illegible] ft., in addition to the various exten-

TEMPERATURES IN DEGREES FAHRENHEIT IN NEW YORK CITY, NOVEMBER, 1913-MARCH, 1914

	Nov.	Dec.	Jan.	Feb.	Mar.
Mean	46.9	38.8	31.4	25.3	[illegible]
Maximum	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Minimum	28	19	−5	−2	11

While construction for the north end of the building was going on, materials were ordered, shipped and received and stored in the vicinity of the mixing plant, which was located on the center of the north part of the building. In this way, there was stored enough sand and gravel inside the building to complete the job, and at one time 36,000 bags of cement were stored, covered with tarpaulin, ready for use. This precaution insured the quick completion of the job independent of slow winter delivery. Inside of the completed part were installed arrangements for heating the sand and gravel, water barrel, steel reinforcement and the forms.

Fig. 1. Tarpaulins over Wall Openings during Winter Concreting; New York Consolidated Card Co. Building, Long Island City

sions for power house, garage and [illegible]. The plant called for about 10,000 cu.yd. of concrete. [illegible] of the north part of the building, [illegible] it was decided to push the work [illegible]. Excavation for the [illegible] of the north part was started on Oct. [illegible], 1912, and [illegible] at that end of the building on Dec. [illegible], 1912. Construction on the south end started Nov. [illegible], 1913, and the roof was completed Jan. [illegible], 1914. For the five months from November, 1913, to March, 1914, the range of temperature at New York City was as shown in the following table. It will be seen that particularly in January and February, when the south end of the building was under construction, extremely cold weather prevailed.

The precautions taken comprised the heating of the sand and gravel on griddles of steam coils, connecting the water barrel to a steam jet and running a steam pipe to the mixing floor, so that the reinforcing rods could be sprayed with steam immediately before placing to prevent any ice particles adhering thereto. Then each floor, immediately after concreting, was completely protected by tarpaulins, above and on the outside, and salamanders (open stoves burning coke) were placed on the floor beneath, and holes left in the floor forms to allow the heat to find its way up to the floor.

The three accompanying photographs show various views of the concreting work in the cold weather. Fig. 1 shows the tarpaulin hung over the side of the building and fastened, completely enclosing the portion of the structure to be concreted. This precaution was necessary to prevent the coldness and to hold the heat for the pro-

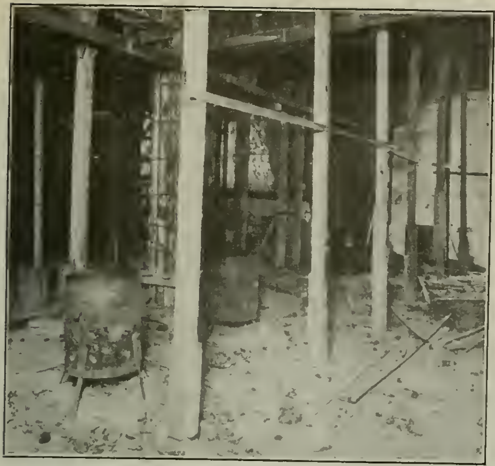

FIG. 2. INTERIOR OF BUILDING, SHOWING SALAMANDERS HEATING NEW CONCRETE FLOOR ABOVE

tection of the floor above. Fig. 2 shows the interior of the same floor with the tarpaulin on the outside wall and the salamanders, one of which was placed for every 300 sq.ft. of floor area, in action heating up the floor in the wooden tower. Forms were made up for about 75% of the building, this work being greatly facilitated by the use of a small circular saw run by a 5-hp. motor.

In hoisting steel and material to the working floor, a tower similar to the concrete tower was used and located at the side of the building with one leg of the tower equipped with a derrick. The advantage of the tower over the derrick mounted on the working floor is that construction of part of the floor does not have to be held up while erecting and handling material. For pulling and setting forms, a small A-frame equipped with block and tackle was used. Stone was dumped in the depressed bins in the street, from which it fed by gravity to a bucket conveyor, and by this means was deposited to the center of the building adjacent to the mixing plant, thereby greatly reducing the cost of its handling. All of these conveyors and hoists were operated by electricity.

To insure the heating of the material, 765,000 lb. of coke, 50,000 sq.ft. of canvas and 71 salamanders were used in the construction of the building. The contractor states that there was a slight increased cost for the winter weather construction over summer weather construction, but that a complete and careful organization served to offset some of this extra cost, and the increased profit due to earlier completion should be taken into consideration.

Ballinger & Perrot, Philadelphia and New York, were

FIG. 3. TARPAULINS COVERING FLOOR JUST LAID, JAN. 16, 1914
(Minimum temperature record: Jan. 13, 5°; Jan. 14, 5°; Jan. 15, 15°; Jan. 16, 29°.)

inclosure. Fig. 3 shows a view of a finished floor with the tarpaulin, which was hung on scantlings 12 in. above the floor, immediately after the placing of the concrete.

For the construction of the building only one mixing plant was used. This plant was located about in the center of the north end of the building, which made it necessary to leave a small opening in each floor in which to operate the hoist. The mixer was sunk about 5 ft. below the first floor level, thereby making a charging operation merely one of dumping and not of pushing a heavy load up an incline. The mixer was run by a small motor, which also operated an automatic dumping bucket the architects and engineers for the building, and the Turner Construction Co., of New York City, the general contractor. To the latter was due the method of winter construction described above.

⁂

Production of Slate in the United States, in 1913, was valued at $6,175,456, an increase over 1912 of $132,158, or 2.19%. This advance, according to A. T. Coons, of the U. S. Geological Survey, was caused by an increase in the average price and not due to increased production. The average price per square (100 sq.ft.) of roofing slate has fluctuated but little in the past 10 years; it was $3.78 in 1904, $3.87 in 1912, and $4 in 1913. About 72% of the 1913 figure was for roofing slate.

Field and Office

Contractor's Scows for the Fraser River

In the construction of the Grand Trunk Pacific Ry. along the Fraser River, in British Columbia, the river afforded the only means of transportation for distributing plant and material to different points at which work was to be commenced. This was a dangerous service, as at high water (the only navigable condition) the river has a swift current with numerous bends and rapids. From Tete Jaune Cache some of the material was carried in small stern-wheel river steamers built for the work by

FIG. 1. FORWARDING CONTRACTOR'S PLANT AND SUPPLIES BY SCOWS ON THE FRASER RIVER, GRAND TRUNK PACIFIC RY.

(A rock at this point, located just to the left of the boat in the [illegible] currents [illegible] the current tended to throw the scows against it.)

Foley, Welch & Stewart (of Winnipeg), contractors for the grading. But the great bulk of the machinery, material and supplies was transported in large scows, carried down by the current and controlled by a long oar or sweep at each end. Steam shovels, dump cars, cement, [illegible] piling, food supplies, etc., were handled in this way, and freighted for distances of 150 to 300 miles. Fig. 1 gives an idea of the character of this transportation.

Fig. 2 shows the construction of the scow, of which over 200 were built by the Bates & Rogers Construction Co. (of Chicago), contractors for all the bridge substructure work. The hull is 36 ft. long on the bottom, 44 ft. on top, 12 ft. wide and 4 ft. deep, with a carrying capacity of 20 tons. At each end is a V-shaped outrigger, with a notch in the end forming a guide for the sweep. All joints are calked. The sides can be raised 12 in. by a line of 12-in. splash boards, but these are used only in rough water or for cargoes liable to be damaged by spray. For the drawing we are indebted to W. C. Ruegnitz, Superintendent for the Bates & Rogers Construction Co.

A Few Motor-Truck Novelties for Contractors

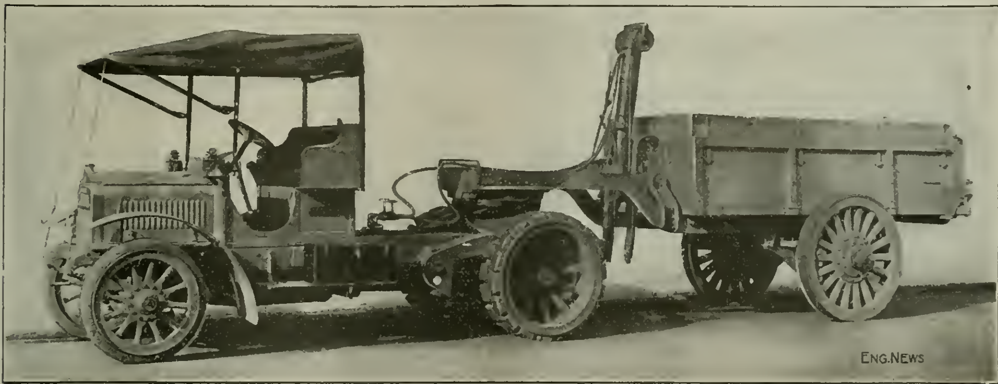
A TRACTOR-TRAILER OUTFIT FOR CARRYING HOT ASPHALT

An interesting and novel motor vehicle, in use by the Borough Asphalt Co., Brooklyn, New York, is shown in the accompanying figure. It is a truck with trailer body of 5 ton (100-cu.ft.) capacity, equipped with a hydraulic-hoist dump. Such trailer outfits are claimed to give greater flexibility of operation, permitting heavy loads to be handled in rough service where an ordinary truck could not pull out. In this case, the trailer body is of wood, $10\frac{1}{2}$ ft. long, $4\frac{1}{2}$ ft. wide at the front, 5 ft. wide at the rear and 2 ft. high. There is a sheet-steel lining, laid over $\frac{1}{2}$ in. of asbestos board and made tight for carrying hot asphalt-pavement materials—though it should be as serviceable as any truck for hauling sand and gravel.

The body dumps at the rear end, being raised [illegible] by mechanism controlled from the driver's seat. The tilting device comprises a cylinder and piston on the trailer and an oil pump on the tractor, with hose connections. The pump is driven from the [illegible] shaft by sprocket and chain with a disengaging clutch. Oil is forced into the bottom of the cylinder under pressure up to 800 lb. per sq.in. On the piston end at its exposed end is a crosshead and this in turn carries a pair of sheaves over each of which runs a cable connecting [illegible] along the front of the body to an equalizing bar on the trailer frame. A pipe leading to the pump [illegible] connects with a cylinder port near the upper end and when the limit of travel is reached, pressure under the piston is relieved through this. The return is by gravity, valves at the pump allowing the oil to flow in reverse [illegible] beneath the pump.

The connection between truck and trailer is by a [illegible] universal joint. A flat steel ring is fastened to the rear of the truck frame. This supports, in a recess, the lower half of the universal joint, allowing free horizontal

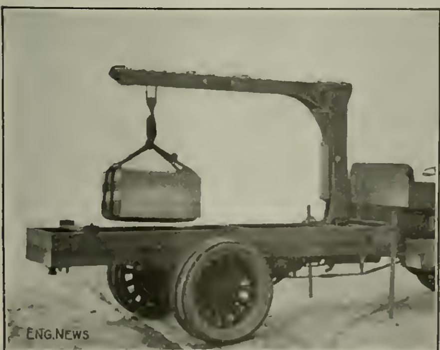
rotation of it. A long, horizontal pin is held in heavy trunnions on the lower half and engages, at right angles, a removable horizontal pin which passes through the trunnions of the inverted third or upper part of the joint. This last further bears a toothed plate engaging with a duplicate on the trailer frame but easily disengaged by pulling a horizontal bolt. A couple of spiral springs between the upper and lower parts of the joint stiffen it against sidewise rocking. The tractor and trailer shown (Saurer type) were made by the International Motor Co., New York City; the dumping hoist was made by the Wood Hydraulic Hoist Co., St. Paul, Minn.

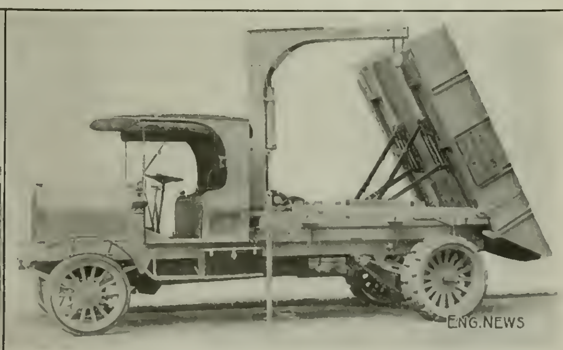


A Tractor-Trailer Outfit for Hot Asphalt

A Crane for Motor Trucks

The wider use of heavy motor tracks has brought an increasing number of instances of trouble in unloading at destinations where there is no particular handling equipment. To meet this difficulty, in some cases special cranes have been installed on the truck chassis, one example (used by the Pullman Co., at Chicago) being shown at the left in the accompanying figure—a pillar-and-jib crane of one ton capacity. A structural-steel mast with jib rotates (on a roller thrust bearing) about a steel casting bolted to the chassis frame. A vertical hoist shaft extends from the head of the pillar through the chassis and is geared to a horizontal shaft below. This last in turn is driven through chains and sprockets (and an idler shaft to reduce speed) from the main transmission. The horizontal hoisting shaft has a double jaw clutch worked by raising or lowering a lever behind the driver's seat; this throws one or the other of two bevel gears into mesh with a gear on the vertical shaft, according as the crane has to hoist or lower. This vertical shaft is bevelgeared to a short horizontal shaft, at the top of the pillar, bearing a chain sprocket, over which the dead-ended hoist chain passes. The cylinder on the mast holds the excess length of chain when the hook is up. The jib arm is formed by two channels with flanges turned in. The crane trolley, running on the bottom flanges, is moved in and out by a hand chain and sprocket. Swinging is done by hand. Outrigger supports, made of iron pipe, are provided to prevent overturning the truck, and the chassis is reinforced by a steel top frame. The outfit shown was built by the Brown Hoisting Machinery Co., and the Peerless Motor Co., of Cleveland.





A Power Crane for Motor Trucks

The 7½-ton dumping truck with crane shown at the right was recently delivered to the Bureau of Sewers, Borough of the Bronx, New York City. It was intended to facilitate hoisting sediment from sewer manholes and loading it, which work has previously been done by hand or with a small tripod derrick. The crane has a capacity of 1½ tons; the body is water-tight and has a capacity of 3½ cu.yd. The dumping is at the rear end, the body being raised through 60° angle by a hand hoist, the

ments an arrangement of arms, cables, drums and gears. The body is lowered by gravity and is controlled by a hand brake on the drums. The truck is a Mack type made by the International Motor Co., New York.

THE HYDRAULIC HOIST ON MOTOR TRUCKS*

The modern hydraulic hoist for dumping motor trucks, in which a rotary oil pump is mounted with hoist cyl-

HYDRAULIC MOTOR-TRUCK HOIST IN OPERATION, (JULY, 1911)

inder carrying the oil reservoir in the head of the cylinder, was successfully applied by the Pierce-Arrow Motor Co., Buffalo, N. Y., in August, 1912. The pump is started by lifting a lever located in front of the cab seat. A three-way valve is provided for raising or lowering the hoist. Experience has shown that it is best that the driver get down from the seat to operate the valve, or that his helper operate it, as it is safer and more satisfactory to see exactly where the load is dumped. This cannot be accomplished from the driver's seat as the truck body obscures the view. Fig. 1 shows the details of the hoist and its arrangement on the truck chassis.

The pump is operated through chain sprockets, one situated in front of the cab and another behind. The sprocket at the back of the driver's seat, which connects through a chain directly to the pump, makes a maximum of [illegible] r.p.m. and is controlled by a governor on the motor. The pump itself turns at 800 r.p.m.

The hydraulic cylinder is made from weldless steel tubing, machined and then reamed to a bore of 5 in. The end flanges are screwed on and a seal of iron (melted in blast furnace) run in a groove between the flange and the tube, preventing any leakage. The joint at the head and base is made oiltight by a copper gasket, as shown in Fig. 2. The piston rod is of nickel steel 1⅝ in. in diameter.

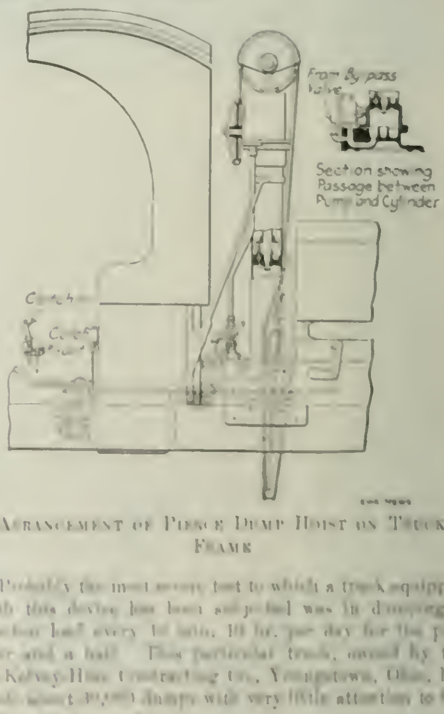
The piston has the usual cup leather. In earlier stages of the development, grooves were cut in the top of the cylinder, so that when the piston reached the limit of its travel the oil bypassed along these grooves. This was found to wear the leather and was abandoned in favor of the present method wherein three small valves in the piston open when in contact with a spacer. By this means the travel of the body can be readily varied.

The piston carries a crosshead at its upper end with two sheaves over which the load-lifting cable passes. A third sheave is placed at right angles to these two on the cylinder head and acts as a compensating sheave for distributing the stresses equally throughout the cable. It incidentally acts for simplicity, in limiting the cable to only two ends. Where a compensating lever is used instead of a sheave, two cables are necessary.

The ends of the cable are connected by yokes to substantial brackets on the front of the body, as shown in Fig. 1. In operation, oil is drawn from the cylinder head, through the three-way valve, through the pump and then under pressure to the bottom of the piston. If it is desired to hold the body in any position, the valve is turned round shutting off the intake pipe. To lower the body the valve is turned round so that the oil is bypassed around the pump from the lower part of the cylinder to the upper. The weight of the body is sufficient to lower the piston.

The oil used is preferably a good grade of ice-machine oil in the winter and a somewhat heavier oil in summer. In fact, the best oil to use depends to some extent upon climatic conditions.

The oil pressure required to lift a full five-ton load plus the body is more than 400 lb. per sq.in. The body can be lifted in 8 sec.



ARRANGEMENT OF PIERCE DUMP HOIST ON TRUCK FRAME

Probably the most severe test to which a truck equipped with this device has been subjected was in dumping a five-ton load every 10 min. 10 hr. per day for the past year and a half. This particular truck, owned by the McKelvey-Hine Contracting Co., Youngstown, Ohio, has made about 30,000 dumps with very little attention to the hoisting equipment.

*By [illegible], Engineer, Truck Department, Pierce-Arrow Motor Car Co., Buffalo, N. Y.

Cutting Out a Large Concrete Turbine Foundation

The removal of large portions of a reinforced-concrete foundation about [illegible] ft. in plan by 12 ft. deep, in the Gold St. Generating Station of the Edison Electric Illuminating Co. of Brooklyn, without interference with the operation of the plant, is being accomplished at the present time, to make way for a new concrete and steel

grillage and steel superstructure for a large horizontal turbo-generator. The concrete foundation was built in 1911 when it was proposed to install a 12,000-kw. vertical unit. It was decided, however, to install a larger unit,

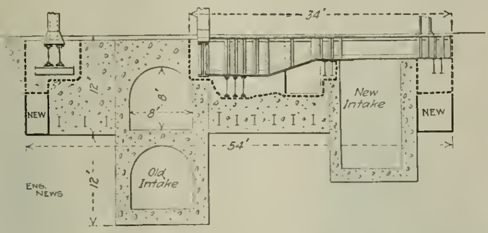


Fig. 1. Reconstructed Turbine Foundation

and because such units are available in the horizontal type at less cost per kilowatt, on account of greater speed, a 22,000-kw. horizontal unit was selected.

The amount of cutting required is indicated on the drawing, which also shows the grillages set for the proposed steel structure. The method employed was to drill a series of 2-in. holes about 6 in. c. to c., 6 in. back of the face, and break down by plug and feathers the material between holes and face. The cutting started along the line of the 30-in. atmospheric exhaust (Fig. 2), situated about 10 in. below the surface, and proceeded in 3- to 4-ft. stages to a maximum depth of 12 ft.

The first step in the whole work was to build a substantial wood screen from the top of the foundation (basement-floor level) to an elevation 6 ft. above the turbine-room floor, through the opening left in the latter floor, for the future unit. This screen or partition served to isolate the concrete-cutting from the various station operations. It was commenced on Aug. 6, by a force of 4 carpenters and 2 laborers.

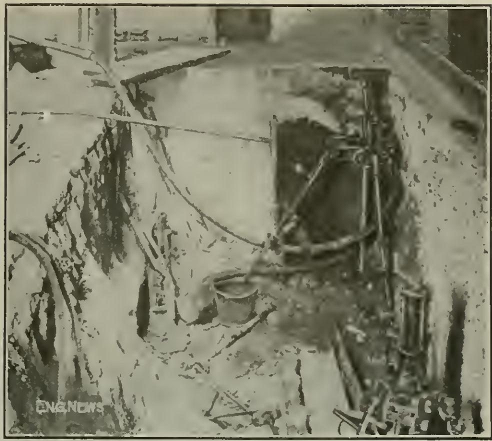

Fig. 3. Opening for Corner Grillages

(For grillages shown at right of Fig. 1. Two drills in place. Gravel concrete at left, broken-stone concrete at right.)

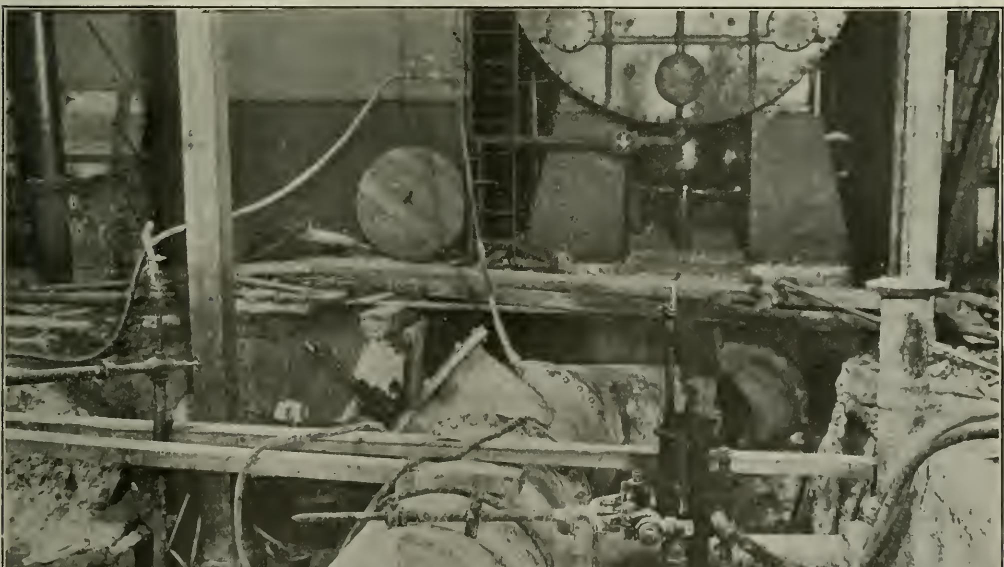

Fig. 2. Main Cut, Showing Atmospheric Exhaust Exposed

(Condenser of adjacent turbine, at top of view. Wood forms at left separated concrete wall of old condensing water tunnels from the concrete turbine foundation. Face at right is gravel concrete.)

FIG. 1. LAND-CLEARING MACHINE

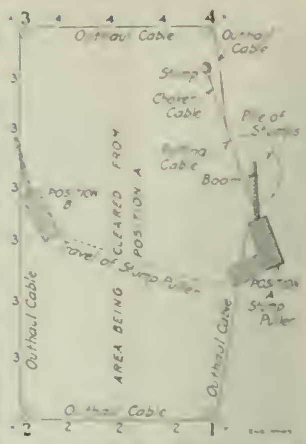

FIG. 2. WORKING ARRANGEMENT IN CLEARING LAND BY MACHINE

To obtain sufficient width it was necessary to cut a slice from an abandoned engine foundation built in 1897. This concrete was a mix of cement, sand and broken stone, while gravel was used in the 1913 structure in place of the stone. The work developed that the older material broke away in chunks under the action of the plug and feathers, but the gravel concrete crumbled, running up the cost of its removal (see Fig. 3, in this connection).

The cutting is carried on by two shifts. The first works from 7 a.m. to 6 p.m. and comprises about 45 men; the night force works from 6 p.m. to 5 a.m. and averages 20 men. A total of 6 drills (both steam and air) were used. The work is scheduled for completion by Oct. 1.

The work is being done by Barth S. Cronin & Co., under the supervision of G. L. Knight, Designing Engineer of the Edison Co.; H. B. Morrow, Chief Inspector.

Stump-Pulling Machine for Clearing Land

In the clearing of timbered land, extensive use is made of machines for hauling, skidding and loading the logs and trees; but there is less general use of machines for the usually slow and heavy work of removing the stumps. The machine here described is intended for the entire work of clearing; it first hauls in and stacks or loads the trees and logs, then it pulls up the stumps, hauls them in, and stacks them ready to be burned. A portable machine, moving from stump to stump and pulling them vertically, was described in ENGINEERING NEWS, Aug. 27, 1914; but the machine described below will clear a tract of 5 or more acres (about [illegible] sq.ft.) at one setting, and it pulls the stumps with a horizontal cable.

The machine, shown in Fig. 1, consists of a frame of three steel I-beams mounted on a pair of longitudinal 9-in. I-beams which form the runners. Each runner is turned upward to enable the machine to ride over obstructions, and is shod with a steel plate 20 in. wide. Steel sheets are riveted to the bottom of the framework of the frame to protect the machinery from dirt and to give additional support on very soft ground. At the front end is a steel A-frame, 16 ft. high, to which are attached the guy lines of the 36-ft. boom. At the rear end is the hoisting engine and a vertical boiler, and over it may be a canopy roof for the protection of the operator. The frame is 32x9 ft., and the machine (with its cables and all equipment complete) weighs about 35 tons. Lighter machines of the same type are built.

A double-cylinder three-drum engine is used, with cylinders 10x12 in. for the larger machines. The front drum carries the pulling cable, and is geared for two speeds; for pulling the stump it exerts a pull of 145,000 lb. with a speed of 30 ft. per min., while for skidding or hauling in the stump it has a speed of 350 ft. per min. The rear drum carries the outhaul cable for running out the pulling cable after it has brought in a stump, giving a speed of 800 ft. per min. The middle drum carries the piling line which is led over the boom and is used for stacking the stumps in piles ready for burning. The hoisting capacity is 10 tons.

When the machine is in position it is anchored by steel spuds driven into the ground through holes in the runners, or by chains attached to trees or stumps at the rear. The outhaul cable is then led around the area to be cleared, being passed through snatch blocks, as shown at 1, 2, 3 and 4, in Fig. 2, and led back to the machine, where its end is attached to the pulling cable.

The drum then hauls on the outhaul cable, thus running out the pulling cable to the first stump (Fig. 2). A choker line or short steel cable, having a hook at one end and a loop at the other, is then wrapped around the stump, and the loop is slipped over the hook on the pulling cable. The drum of this cable then hauls in on the slow gear until the stump is pulled from the ground, and then on the high gear until the stump is deposited at the machine. The choker line is released automatically and taken back by the outhaul cable.

When the machine has pulled all the stumps between it and point 4, the snatch block is shifted successively to points in the line 4-3, as shown. Then snatch block No. 4 is dispensed with, and the cable led directly to block No. 3. This in turn is shifted toward No. 2, and is

then removed, and No. 2 is then shifted in the same way. As the positions of the snatch block are changed, the machine swings so that it is always in the line of the direct pull.

The entire area having been cleared, the pulling line is run out and anchored at the next position (shown at *B*, Fig. 2) and by hauling on this cable the machine pulls itself forward to that position. The outhaul cable is then led around the new area and work proceeds as before.

One piece of clearing done in Texas was on heavy clay land with pine stumps 10 to 40 in. diameter averaging 44 per acre. The machine pulled, skidded and piled about 110 stumps per day, at a cost of about 28c. per stump, or $12.32 per acre, clearing about 2½ acres per day. The working force was as follows, with a total daily cost of $30:

1 Foreman	$5.00	2 Hookers (each)	$2.00
1 Engineman	3.50	1 Tongman	2.00
1 Leverman	2.00	1 Stump grubber	1.50
1 Fireman	2.00	1 Water team	4.00
1 Helper	2.00	1 Fuel team	4.00

The machine is built by the Clyde Iron Works, of Duluth, Minn.

General Points on Moving Large Structures*

In preparing a building or structure of any kind for raising and moving it will be necessary to make a careful study of the structure. The weight should be carefully estimated, the general construction of the building should be understood, in order to know the distribution of loads on present foundations. The character of ground over which the structure is to be moved should be considered, especially if the building is of a heavy type.

After the above points have been carefully considered, a layout is made showing the manner of picking up the structure, which is done in the case of a brick or stone structure by inserting either beams or heavy cross timbers at proper places to take the load without causing strains in the main structure, when the building is raised. The main principle in raising structures is to keep conditions as nearly as they were, when on original foundations.

*From a paper by Geo. W. Nichols, Engineer, John Eichlacy, Jr., Co., Pittsburgh, Penn., "Principles and Details Involved in the Moving of Large Structures," "Proceedings" of the Engineers' Society of Western Pennsylvania, April, 1914.

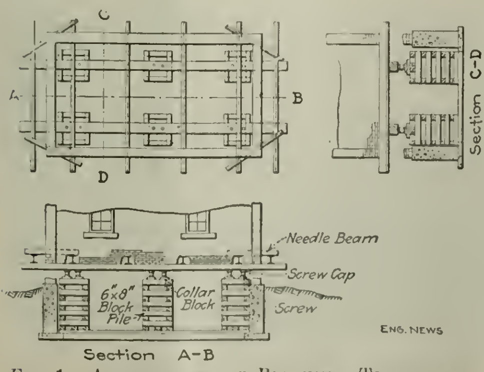

FIG. 1. ARRANGEMENT OF BLOCKING, TIMBERS AND SCREWS FOR RAISING A BUILDING

In the case of steel structures, special consideration is given to each individual case and no set method can be laid down for the work, however, the general principles are applicable to all structures.

The following sketch, Fig. 1, shows the manner of building a blocking and the setting of timbers and arrangement of screws for raising a structure. Regularity and care must be used in building the blocking and in the manner of setting the screws and locating cross-timbers for taking up the building.

After the building has been raised the required height and it is desired to move it, oak runs are built and the building lowered on rollers which bear on 6x8-in. oak runs below and on roller planks above, after which the jackscrews are removed. This is shown by the sketch, Fig. 2.

In case it is desired to turn the building slightly, the rollers can be "cut," that is, set at a slight angle to the general direction and gradually brought over to proper line. Cutting the rollers is a term used for knocking one end of the roller slightly with a hammer to change the general direction of the structure being moved. However, it is sometimes necessary to actually cut the rollers with a saw. Where the building is to be given a quarter or half turn, or a complete turn, a pivot point is selected and runs laid and rollers set to operate about this point (Fig. 3).

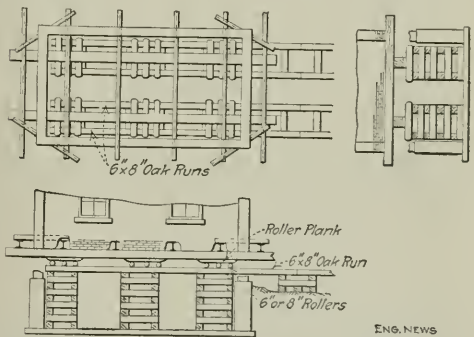

FIG. 2. ARRANGEMENT OF RUNS AND ROLLERS FOR MOVING A BUILDING

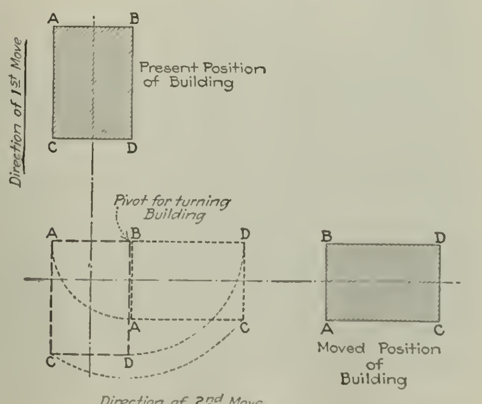

FIG. 3. PLAN FOR MOVING A BUILDING AND MAKING A QUARTER TURN

In the [illegible] of buildings, such as the change in [illegible] or [illegible] of floors or the [illegible] of heavy structures where [illegible] blocking would be required, pump-logs or drums are used. Pump-logs are timbers, usually [illegible] in size, but often larger, one end of which is bored to a [illegible]-in. diameter about 18 in. deep. In this hole operates the screw, the lower part of nut sets in the [illegible]-in. hole in the timber and the flange of nut bears directly on the bottom of timber—more often a collar block is used to form a bearing for the nut. Drums are usually set in position with the screw at the lower end, so that the screw may be more easily operated.

In the raising of brick structures great care is required to keep the building level and the movement uniform. It is usually customary to run cables entirely around the building and tighten by means of ratchets. In attaching the ropes to take the blocks for moving a brick structure, these are not connected directly to any part of the brick building, but to the timber or steel grillage upon which the building sets.

The building is watched carefully by all the men to assure raising in a level position. These levels are [illegible] by means of ordinary carpenters' spirit levels, which are placed on rails and timbers which support the structure and these kept as near level as possible. In raising the building a number of screws are divided among the men. Each man may have ten screws to turn. Each man takes his screws and makes two rounds at a given signal. He starts at one end and makes a quarter turn and goes through to the end of his screws, and then returns and stops until every one else is through and until the signal to turn is given again.

An Erection Economy: Marking Structural Members for their Connections

By [illegible]*

[illegible]

The writer proposed (1) that every shipping member of a structure be marked with the [illegible] of the connecting members at the points where they connect and (2) that each end of each member be marked with its [illegible], e.g., the top with "Top," the end toward the [illegible] "Water End," and so on. Then the erector will [illegible] have to look at the end of the member for the connection symbol, [illegible] the marking on the piece would [illegible] back for [illegible] and send it up.

*[illegible]

Now [illegible] diagram, Fig. 1, and suppose $EG2$ is already in position. The detailing of $EG2$ and its connecting members $TL9$ and $TL10$ is shown in Fig. 2. If, when this girder is assembled in the shop, the marks of the connecting pieces are painted on the gusset plates, the erector will know without the detail drawings how to place these members in the structure, which he otherwise would not know.

The system would work out the same as match-marking. The erector would note the symbol of a connection and call it down to the men on the ground; the latter, in looking onto it to send it up, would be governed by the marking found on the piece as to which end goes which way. The foreman would not have to get the detail drawing and check up a piece to see which is the top or water end, his men waiting for instructions in the meantime. It is hard to work with drawings out in the open, where the wind and possibly rain can get at them; in cold weather it becomes doubly hard.

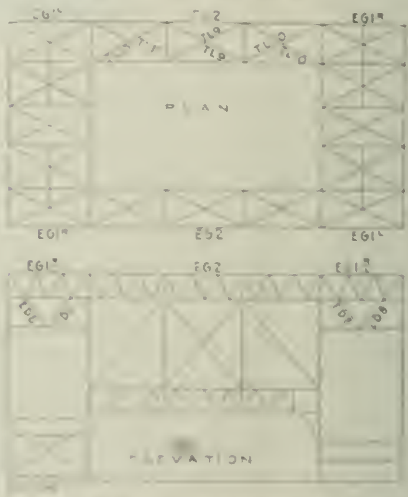

Fig. 1. [illegible] Marking of Members on Erection Diagrams

[illegible]

I have [illegible] jobs where there have been [illegible] and [illegible] Fig. 2 gives a good example of such a case. [illegible] handled by one [illegible] two sets of falsework were used, and on each bridge a raising gang worked at either end, making four gangs to begin with. As soon as one bridge span was complete, the bridge was run off the falsework and another one started, and another gang set to work putting in track stringers and [illegible]. Thus finally [illegible] gangs were raising [illegible].

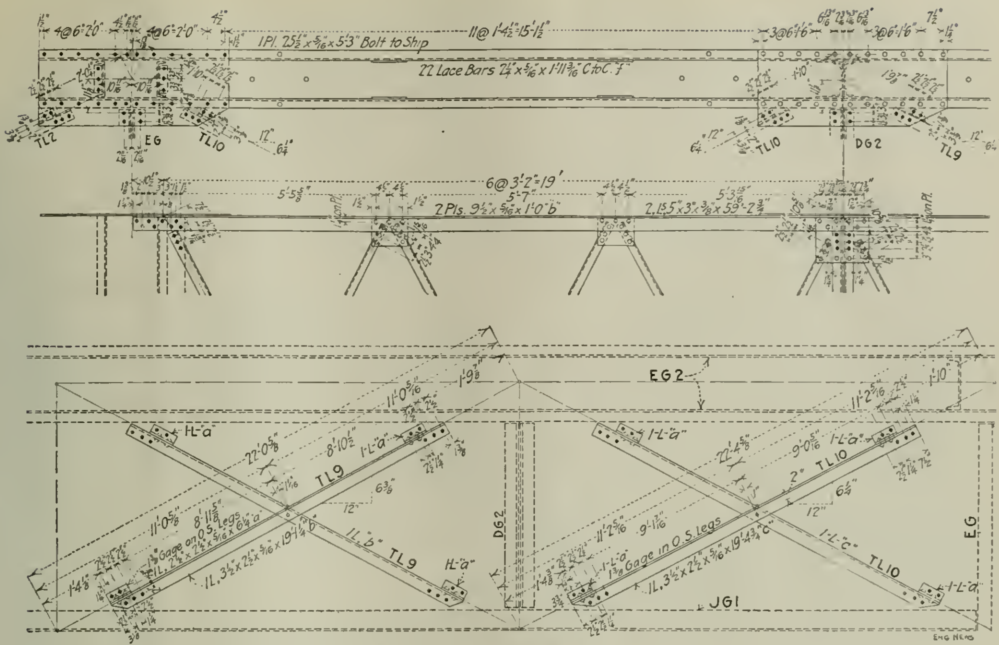

FIG. 2. DETAILS OF THREE MEMBERS OF FIG. 1

and in addition there were machinists and electricians. Since in most cases a blueprint is Greek to the pusher or foreman of the gang, it is necessary that he have someone at work to pick the iron out and mark it as to its location in each bridge. In this case two men were kept busy on such work, and even then mistakes were made, sometimes a piece being put up wrong and taken down again, because they did not have sufficient time to study out the details.

There is no doubt that a great deal of time can be saved and mistakes forestalled by designating in the shop the position a member occupies in the finished structure. To enable the shop to do this properly, the marking should be noted on the detail drawing. The draftsman would need but very little more time to put this information on the drawing, so that the shop can use it on sight.

An argument against adding more information to a detail drawing is that it clutters up the drawing. But the more information is placed on a drawing, the less the

FIG. 3. A GROUP OF ORE BRIDGES ERECTED BY ONE FIELD ORGANIZATION

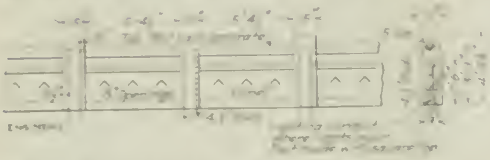
Part of ore-handling plant at Edgar Thompson Steel Works, Bessemer, Penn. Built by Brown Hoisting Machinery Co. Two of the five bridges are at right angles to the three shown, and cannot be seen in the picture.

deep seam grid sections will have to be wired [illegible].

As far as increasing the shop expense, this method would only add to one man's duties, the shop inspector or checker. When he is going over a member for its final inspection, he can perform the necessary marking as called for on the drawing.

A Special Reinforced-Concrete Bridge Railing

A partially precast concrete hand-railing was placed on the Pleasant St. Viaduct of the Delaware, Lackawanna & Western R.R., at Utica, N. Y., by Peters & Kiehm, contractors for the bridge. The accompanying drawing shows the detail of the construction. The railing was divided so that a large 15-in. square post was placed every 13 ft. Midway between these posts was set a smaller 12-in. post, which extended in height only to the center of the top rail and acted as a support to that rail. Between



Railing for Pleasant St. Viaduct, D. L. & W. R.R. Utica, N. Y.

these posts were 5-in. vertical slabs acting as panels and paneled with 8-in. square diamond-shape openings as ornaments.

In building the rail the small intermediate post and the two adjacent panels were first cast in place and were made long enough to extend 2 in. into the main post. After a number of these sections had been cast and the forms removed, the top railing, which was a square section set with a diagonal vertical, and which had been previously cast on the ground was put in place resting in the groove left in the top of the short mid-post. Then forms for the main post were placed and filled, the ends of the panel and of the top rail having been covered with grease and wrapped with paper to provide a slip joint at each of these main posts.

A Rough Wood Suspension Footbridge*

A suspension footbridge 273 ft. long was recently built across the Gila River near Kelvin, Ariz., by the Kelvin-Sultana Copper Co., to connect their mine and power plant and to accommodate miners living in Kelvin. Although designed only for pedestrians, single pieces of machinery weighing 1800 lb. have been taken across. The maximum load placed upon it to date was 3000 lb. The bridge carries a 4-in. pipe line which conveys boiler water from the mine to the power plant.

The general design is shown in the accompanying view. At the center the roadway is 15 ft. above mean high water. The wooden towers are carried on concrete foundations. On the west side of the river (the far side in the view) the former river bottom, now about 8 ft. above mean high water, forms a flat several hundred feet wide which affords poor bearing. The concrete foundations on this side are 14 ft. deep x 6 ft. wide at the base. On the opposite side the piers are about 3 ft. high. The towers, constructed of 10x10-in. Oregon pine posts with 3x8

*Data furnished by Arthur L. Flagg, Kelvin, Ariz., who built the bridge.

General View of 273-Ft. Suspension Bridge

in. bracing, are 21 ft. square at the base and 31 ft. 5 in. high.

The two cables are made each of two 3/4-in. plowsteel ropes, which had seen about six months' service in hoisting. The floor, 4 ft. wide in the clear, is attached by 5/8-in. Ernst patent hangers passing through 4x6-in. cross-bars, on which rest two 4x8-in. and one 3x8-in. stringer. The floor of 2x12 is nailed directly to the stringers. Directly over each side stringer is a 4x6-in. guard timber, bolted through plank and stringer to the cross-bars.

The anchorages are concrete blocks. The cable ends are passed around several 16-ft. lengths of 90-lb. rail embedded in the concrete. On the power-plant side, turnbuckles are provided.

From the center of the bridge there are four guys to the bank, making an angle of 30° with the center line of the bridge. There is very slight sway to the bridge under ordinary loads.

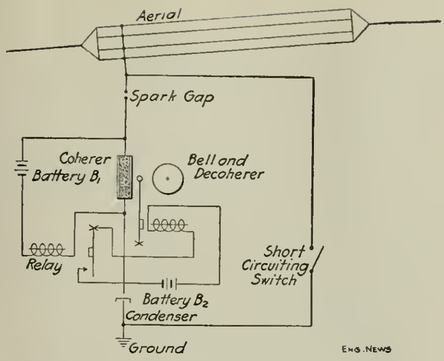
In building the bridge, as soon as the towers were completed the cables were hung and roughly adjusted to nearly the proper deflection. The hangers were then put on, beginning with the longest and working from both ends toward the center simultaneously. When the hangers were all placed, the deflection was adjusted (27.2 ft.), the floor laid, and the handrail put on.

A Detector of Approaching Storms

The storm detector recently developed by the engineers of the New York Edison Co. gives them warning of storms 2 to 7 hours before the actual clouds and darkness arrive and they are enabled to prepare for heavy drafts of lighting currents. The apparatus is very simple and should be of broad application wherever there is work under way which it is advisable to protect in advance from storms and darkness. A few detector stations scattered over the area served by a large electric-transmission network should give advance warning of impending local loads and line disturbances—helping the new art of load dispatching.

Practically all summer storms are accompanied by electrical disturbances, and these are detected by what is virtually a wireless-telegraph receiving circuit. Winter storms have but weak electrical manifestations, and are not yet as well detected.

As shown in the accompanying figure there is an aërial frame, a spark gap, a coherer, a condenser, a ground connection, a combined bell and decoherer, a relay, two batteries and a short-circuiting switch. The spark gap is to shut out radiations from radio-telegraph stations; the spherical terminals are about 1/64 in. apart and storm surges will jump this distance. The coherer is like the earlier ones of wireless telegraphy—a short glass tube of small bore filled with nickel-silver filings between german-silver plugs. The bell is one of single-stroke connection mounted so that the clapper will back-strike the coherer tube. On passage of a storm impulse the coherer loses its high resistance so that steady current flows through it from its battery and causes the bell to tap. The return of the clapper jars the filings and restores the high resistance ready to report another storm impulse. The condenser was inserted in the Edison Company apparatus to prevent direct current from flowing; in many cases it could be omitted. The short-circuiting arrangement is needed to prevent damage to the set when the storm begins to break.



Connection Diagram of Storm Detector

At the New York station, it has been found that the bell begins to tap every 15 to 5 minutes when a storm is a few hours away. If it approaches nearer, then about two hours before it breaks the bell taps every minute or half minute. The bell rings continually an hour or a half-hour before the crux and then the set is short-circuited since no other warning is possible or needed.

Arrangements for Soil-Loading Tests

That the rather uncommon operation of testing the bearing capacity of foundation soil involves a number of troubles and complications was commented upon editorially in our issue of September 3, 1914. The following two descriptions of test arrangements which have proved satisfactory in actual use, received in response to our comments, may be instructive.

UNBRACED LOAD BALANCED ON SINGLE POST

Wm. P. Snow, Lewiston, Me., several years ago made soil tests with load balanced on a single post, as follows:

A large chimney was to be built close to a river bank and the bearing capacity of the subsoil had to be determined before designing the foundation. A test-pit was excavated to the proposed foundation depth, and showed a good coarse gravel, which was capable of carrying a heavy loading. While this gravel did not seem to call for the proposed test nevertheless the test was carried out for the information of outside parties.

A 12x12-in. iron plate was set level on the bottom of the pit and on it was placed a 10x12-in. post with top about 2 ft. above ground. When this post was carefully plumbed the hole was backfilled around it. A 12x16-in. timber 20 ft. long was laid over the top of the post as a loading beam. Under each end of it a timber crib was built to within a few inches of the beam, as a stop in case it got out of balance. Bricks were piled on the loading beam until the required intensity of loading was reached. There was no trouble in keeping the load balanced, the bricks being added with reasonable uniformity on either side of the post.

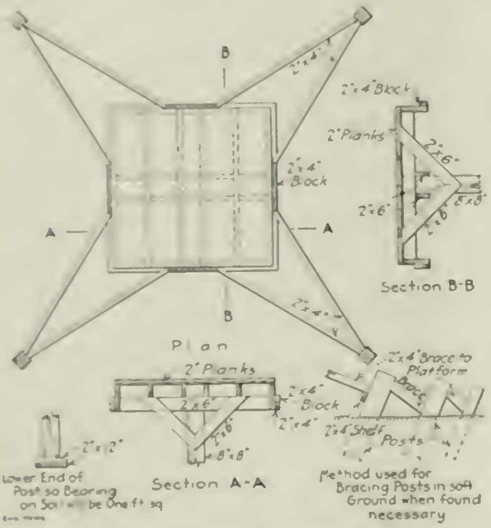
There was a slight compression under the first thousand pounds of load, but thereafter little or no settlement was perceptible up to the maximum applied loading of four or five tons per sq.ft. This test was carried out for Lockwood Greene & Co.

A similar test was made some time later on top of the ground, without backfill around the loading post, and there was no trouble in maintaining balance of the load on the post

BRACED PLATFORM ON SINGLE POST

The [illegible] arrangement described and shown in the [illegible] been used by E. McCullough, Chicago, in a number of [illegible] tests for building foundations.

The platform, of at least [illegible] tons capacity, is 6x6 ft., made of 2-in. planks resting on an outer frame of 2x12-in. plank and stiffened by four 2x6 joists below. Two additional 2x6's underneath these joists support the platform and are spiked to the middle post. The post is 8x8 or larger. The platform is braced to it by inclined 2x6 knees. The bearing area at the bottom of the post should be 1 sq. ft. This is



Braced Loading Platform Used by E. McCullough

obtained by spiking to the foot of the post two thicknesses of 2-in. plank with the fibers crossed. There is no necessity of using a 12x12 post. It is much simpler to make a shoe as thus described than to build up the post of plank to get the proper bearing area at the bottom.

To receive the ends of props on the four sides of the platform a 2x4 strip is nailed around the outside of the frame along the lower edge of the 2x12 frame support, and at the middle of each side a piece of 2x4 about [illegible] ft. long is spiked on top of this strip, forming a lug against which props can be located.

About five or six feet away from each corner of the platform a large post is driven, and if necessary it is braced. [illegible]

Concussion Effects in Pavements; Information on Tests Wanted

There is a good deal of difference of opinion as to whether 6 in. of cement-concrete foundation is sufficient for heavy-traffic street pavements. One of the arguments for heavier foundations is that thin foundation slabs may be fractured by vibrations produced by heavy vehicles passing at high speed. But no experimental study has been made of this phase of the pavement problem, so far as we are able to find.

Several important practical questions come up in this connection. Two fundamental questions are:

1. *Is one kind of pavement surfacing as hard on the foundation as another?*

2. *Does asphalt or wood-block surface have a cushioning effect, as compared with brick or stone block? Which results in longer life of the foundation?*

Answers to these questions are solicited. Further, if any tests or measurements have been made of vibration (concussion) effects in pavements, we would be glad to hear of it.

NOTES

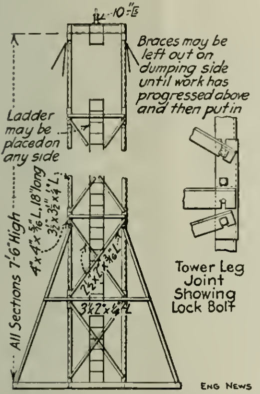
Selfcomputing Leveling Rod—A new leveling rod has the number face on an endless steel tape instead of on the fixed material of the rod, and, the tape being carried on two end rollers, the graduations can be set to match the elevation of the benchmark. Thus the level-reading on any stake gives its elevation direct, without any addition, subtraction or other of the usual level-record computations. In construction the rod is simple, the tape roller at either end is the chief addition to the ordinary rod. The tape is joined by a hook joint in the rear half, and it can be taken off and replaced with

[illegible] Rod, Tape Roller and Clamp; Selfcomputing Leveling Rod

very little trouble. A winding reel may be attached near the bottom end of the rod, for use in putting the ribbon on the rod and taking it off. Of course, the graduations on the tape increase from top to bottom, as on an inverted rod, though the figures themselves are right side up.

The rod itself is made in three sections with telescope joints, so that for transportation it can be brought down to a length of 4½ ft. An oval target sliding on the rod in the usual way enables the rod to be used as target rod, although with suitable graduations it is probably best adapted for self-reading work. The face of the rod is made wider than that of the usual target rod, and this helps in reading from the instrument. The rod can be made with any desired graduations. The Chicago Steel Tape Co., 6231 Cottage Grove Ave., Chicago, makes and sells the new rod. The present list price is in the neighborhood of $17.

Steel Concreting Tower Designed for Rapid Erection—Slots in place of bolt-holes are the essential feature of a steel concreting tower which the Yorke Derrick Co., Washington, Penn., has just begun to manufacture. The parts of the tower are put together or dismantled without removing nuts or bolts, but slip apart as soon as the nuts are slacked off. This applies to the splices of the tower legs as well as to the attachment of the horizontal struts and diagonals. The leg splices are made by means of a piece of angle 18 in. long riveted to the end of one of the leg sections and projecting to engage the other; its end is slotted, and two bolts in the engaged leg section enter the slot, while similarly two slots in that section receive two bolts in the splice angle. Thus the two leg sections go together by a simple telescope joint, which is held firm by tightening the four bolts.



STEEL CONCRETING TOWER WITH SLOTTED BOLT-HOLES

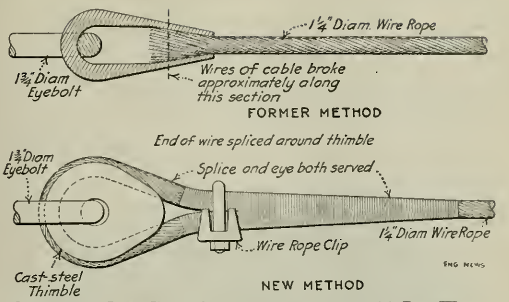
This principle of construction has been used by the same company for a long time in building oil derricks, but only recently has been applied to a concreting tower. The new tower is being made in sizes of 4 ft. to 5 ft. clear width of hoistway, and in any height. The sections are 7½ ft. high, except that guides and ladder are put on in 15-ft. lengths. The adjoining sketch shows the construction clearly. At the top of the tower a 10-in. channel on each of two opposite faces of the tower, taking the place of the regular strut, furnishes a support for the sheave beams. The top frame can be connected at the end of any tower section in place of the horizontal struts and the succeeding tower section.

A single tower section weighs about 500 lb. and the base section (base spread to 15-ft. length) weighs 800 lb.

Cable Socket Break and New Type of Cable Connection—The breaking of a 1¼-in. wire rope cable socket on the U. S. seagoing suction dredge "New Orleans" a year ago, as described by Maj. E. H. Schulz in "Professional Memoirs," Sept.-Oct., 1914, led to the design of a new cable attachment which is now used. Two 1¼-in. ropes hold up the dredge arm. On Sept. 23, 1913, while at work on the outer bar of Southwest Pass, both these ropes broke at the sockets, dropping the dredge arm. In attempting to lift the arm there was a series of breaks of cables and of hoisting tackle as a result of which it was ten days before the arm was finally raised and secured again.

Two similar socket connections were tested at Tulane University. They broke at loads of 53,000 and 58,000 lb., although the initial stages of fracture occurred at 44,000 and 38,000 lb. respectively. The cable itself is advertised to have a breaking strength of 100,000 lb., but a piece tested with leaded end connections broke at 89,000 lb., the first stages of fracture occurring at 63,000 lb.

As a result of the accident to the dredge and the tests, the socket connection was concluded to be undesirable and a spliced-in eye connection was employed. (See sketch). The cable is spliced around a thimble, the splice served with wire, and the end of the loop close to the thimble held by

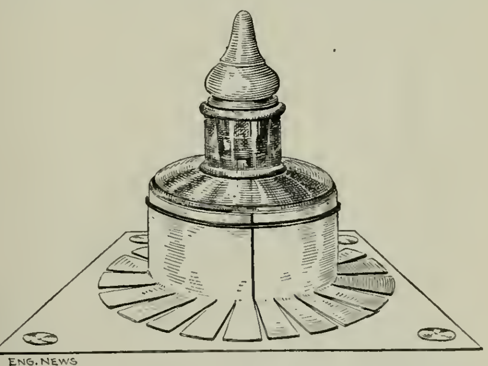


OLD AND NEW END CONNECTIONS FOR 1¼-IN. WIRE ROPES HOLDING DREDGE ARM, U. S. SUCTION DREDGE "NEW ORLEANS"

a Crosby clip. The old method of connection is described as follows: The ends of the wire were passed through the socket; served inside the socket with wire; end unlaced; heart taken out; ends of wire bent over into the socket; and spike driven into the heart. The ends were then seized together and pulled into the socket with the tackle. After the end was pulled in, the socket was poured full of Magnolia white metal and allowed to cool. The new eye connection has not been tested so far as reported.

A Simple Ink-Bottle Holder—An even simpler ink-bottle holder than that described in this department on May 28, been called to mind by a correspondent.

First wrap a piece of drawing paper around the bottle and hold in place by means of rubber bands. Then cut the projecting portion into strips. Next, bend the strips over



ANOTHER INK-BOTTLE HOLDER

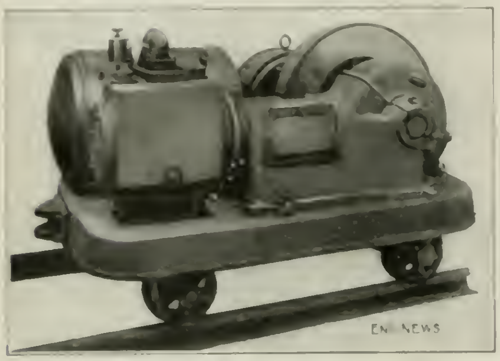
and paste on another piece of drawing paper, and fasten to the drawing board or drawing table with thumb tacks, as illustrated in the cut.

The disadvantage of immovability could be overcome by fastening to a block of wood ,instead of to the drafting table.

How to Turn a Revolving Shovel in a Small Space—The ordinary method of turning a revolving shovel around in a cut is generally a rather lengthy process of backing and filing. A much quicker and simpler method is given below, but we do not recommend this unless the operator is pretty sure of himself. Suppose it is desired to make a right angle turn to the right. Swing the shovel until the boom is over the steering axle wheel, the opposite way from the direction in which it is desired to move. Drop the dipper to the ground, then thrust down with the crowding engines and at the same time propel ahead. This will raise the front wheels off the ground. The hog rods will probably be slack at this time. Then swing. This will slue the rear wheels. By repeating this two or three times, a right angle turn may be effected. Another method which is often practiced when it does not seem advisable to slue because of the condition of the ground or other reasons, is to slip fishplates under the front wheels, with the flanges pointing in the direction in which it is de-

[illegible] to turn the shovel. Propelling the shovel against these flanges will cause the wheels to slip on the plates and turn in the proper direction. [The "Excavating Engineer" for July, 1914.]

A Portable Electric Compressor Unit for mines and industrial plants where tracks are laid is shown in the accompanying figure, as developed by the Sullivan Machinery Co., of Chicago. A rugged design of compressor is mounted on a bedplate casting together with a 1?-hp. motor, storage tank and starting rheostat. The bedplate forms the truck.



A PORTABLE ELECTRIC COMPRESSOR UNIT

Storage Battery Emergency and Construction Car—The accompanying figure shows one of four emergency, wrecking and construction cars built by the Field Omnibus Co., of New York, for the Havana Central R.R. The cars will operate from the overhead trolley on certain sections of the line and from storage batteries where there is no overhead construction. The battery (a 2?0-cell Edison nickel-iron) may be charged directly at trolley voltage. The speed on trolley current is ?? miles per hour, and 20 on the batteries; 70 miles run per charge was guaranteed and reported exceeded by [illegible]. A hoist motor and air compressor are operated by

STORAGE BATTERY EMERGENCY AND CONSTRUCTION CAR

battery current. For propulsion, there are two [illegible]-hp. motors, [illegible] [illegible] [illegible] the Pennsylvania R.R. The car is not intended as a locomotive, [illegible] grade, running [illegible].

A Special Pipe Cutter and Die Stock is [illegible]

A Rivet Buster, to be used in place of a rivet set with a pneumatic riveting hammer, has recently been brought out by the Ingersoll-Rand Co., of New York City. This is a small chisel with the socket end shaped, as with the rivet set, to be held in place by a safety spring.

Highway Notes

Kinds of Road Construction in New York State—Since May, 1913, the New York State Highway Department has placed under contract a total of 1003.12 miles of highways. These contracts are made up of the following mileage under different types of construction:

Waterbound macadam	266.90
Waterbound macadam, hot oil	10.87
Waterbound macadam, cold oil	10.[illegible]6
Bituminous macadam	3[illegible]2.31
Concrete	217.13
Concrete, bituminous top	8.31
Brick	90.[illegible]3
Asphalt block	6.83
Stone block	1.[illegible]3
Other types	19.22

Combination Concrete Storm Drain and Road—A method of taking care of the semi-annual runoff of large volumes of water by building a concrete trough 24 ft. wide and 12 in. deep, which serves as a drainage ditch in wet weather and as road in dry weather, has proved both economical and efficient, in a ranch section about 15 miles from Los Angeles, Calif. The pavement surface is a flat slab 24 ft. wide and 4 in. thick. The concrete curb is 12 in. high, 12 in. wide at the base and 5 in. wide at the top. At road intersections the curb flares out like the edge of a saucer. Transverse expansion joints are placed every 25 ft. The pavement surface is covered with Ott 95% wood oil spread ½ gal. per sq.yd., over which is sprinkled sand and crushed stone. The combined road and drain is 4500 ft. long and cost $1.05 per sq.yd. for the pavement and 30c. per lin.ft. for the curb. F. H. Joyner was engineer and the Davidson Construction Co., of Los Angeles, the contractor. [Information from the September issue of "Western Engineering."]

The Economy of Road Machinery—Many townships in Illinois have chosen to do all road grading and leveling with a heavy power machine and leveler. Such equipment has proven quite satisfactory for heavy grading work, but a little expensive for leveling work. Experience shows that the cost of running a tractor and leveler, including helpers, is from $12 to $1? per day, exclusive of the heavy depreciation and interest on the investment, which may vary from $?00 to $700 annually. Assuming that the tractor outfit will cover 15 miles per day, and that it is used by the average township 40 days out of the year, it would cost between $2 and $3 per mile for maintenance work, which is about double the cost of maintenance work with the ordinary drag. However, if the same equipment could be used for six months in each year, the outfit would be much more efficient and would probably not have as high an annual depreciation, as a more competent operator could be secured for this length of service. This, therefore, would indicate that such equipment should be owned by the counties, and leased to the townships and districts at actual cost, rather than all individual townships buying such equipment. [R. H. [illegible], Assistant Engineer, Illinois State Highway Department, in July issue of "Illinois Highways."]

Some New York State Experience with Tar-Covered Concrete Roads—Many miles of concrete road construction exist in the vicinity of Syracuse. These roads are of more than local interest and are being observed by road builders in different parts of the country. It is worth while here to explain that the wearing surface of these roads is a [illegible] of tar and stone screenings, sand or fine gravel. This cover has not as yet yielded perfect results. The idea in placing it is to obtain an economical wearing surface which can be easily repaired at a low expense, while the real body and foundation of the road remain practically permanent. Experience in the past two years has shown that it is difficult to get this cover to adhere perfectly to the concrete. It wears off in spots and in others is unable to take the wear [illegible]. During the present summer several miles of these [illegible] have been repaired, and if the appearance of the work is any criterion, it seems that the patches will give good service. It also seems probable on account of the [illegible] of [illegible] that the first cover can be applied with the expectation that about one-half of it will come off the first season, requiring patching the following year and still be an economical proposition. The aim of our experiments, however, is to be able to apply this cover so that the first application will require only occasional repairs.—Chas. I. [illegible], Assistant Engineer, New York State Highway Department, in August issue of the "New York Highway News."

Editorials

The River and Harbor Bill

The searching criticism of the River and Harbor Bill by Senator Burton, of Ohio, referred to in our last issue, finally caused the Senate on Sept. 21, to refer the $53,000,000 bill back to the committee with instructions to report a new bill carrying appropriations of not more than $20,000,000, thus saving on this one appropriation bill alone substantially a third of the amount necessary to offset the deficit in the government's revenues due to the war abroad.

There need be no alarm that the interests of the country are to suffer and that necessary river and harbor work is to be suspended because of this sweeping cut in the River and Harbor Bill, for as Senator Burton showed, in his masterly review before the Senate, there is a large amount of money still available from previous years' appropriations with which river and harbor work can be prosecuted.

The unexpended appropriations for river and harbor work on June 30 last amounted to the sum of $45,338,000. In addition to that, the sundry civil appropriation bill, approved on Aug. 1, provided $7,000,000 additional. Thus there is over $52,000,000 of money available for river and harbor work this year without passing any appropriation bill at all. This is far more than the amount which has been expended in any year on river and harbor work. In 1912, the total expenditure on rivers and harbors was in the neighborhood of $33,000,000. In 1913, it was about $38,000,000. If then, the River and Harbor Bill of this session passes carrying appropriations of $20,000,000, there will be $72,000,000 available for river and harbor work in the treasury, or enough to carry the work onward for two years at the same rate of progress as in the year 1913. On the face of these figures there can be no question that the government is providing sufficient money for river and harbor improvement to carry on all works that can be justified on the ground that they render a public benefit proportionate to their cost.

Bringing Spanish-American Students to United States Engineering Schools

A correspondent in last week's issue., discussing the prospects for American engineers and manufacturers in South America, suggests that a large proportion of the young men from the wealthy families of Argentine finish their education in the schools and colleges of France and traced to this influence the tendency in Buenos Aires to give preference to French styles of architecture and French methods of engineering work.

It is well known that South America has been always more closely in touch with Europe than with the United States. The similarity in language and in customs has something to do, doubtless, in attracting South Americans going abroad for an education to the Continent, rather than to the United States. To those who are to study engineering, however, there can be little doubt that the training they could obtain at a first-class engineering school in the United States would be much more valuable than that given in European schools. These naturally follow European practice and methods which are not as well adapted to American conditions as practice in the United States. Besides this, the advantage to Spanish-American students in studying engineering and acquiring a command of the English language is an advantage of great importance, since it makes available to them the largest volume of professional literature.

It would seem well worth while for American engineering schools to make a distinct effort at this time to attract students from South and Central America. Engineers who obtain their education here and become familiar with American methods and commercial customs, will be much more apt to use American methods, materials and machinery on their return to their native land to take up actual work, than they would had they been educated in Europe. It is true that in the past a considerable number of Spanish-American students have come to some of the American engineering schools, notably to Rensselaer and to Cornell. As far as we are aware, however, no special effort to bring students from foreign countries to the United States has ever been made, and it would seem well worth while for some of our leading schools to seek coöperation with the newly organized Bureau of Foregn Trade, in order to make their facilities and the advantages they offer more widely known in the countries to the south. Nor need this effort to obtain foregn students, with a far look to the future of American trade, be confined to the New World. With the difficult conditions which may continue in Europe for some time to come, it should be possible to divert to the United States numerous students from Russia, China, South Africa, and other lands. China, indeed, is already sending large numbers of students here. The great favor in which the United States is held in China is partly the result of the work of our missionaries there, and also of our fair treatment of the Chinese nation in connection with the Boxer war indemnity. The latter especially has a most favorable influence upon the development of our future commercial relations with that vast country.

The Winnipeg Municipal Electric Plant

The valuable article published elsewhere in this issue describing the results obtained by the City of Winnipeg with its new municipal electric-lighting plant deserves the careful study of engineers interested in the current discussion concerning the possibility of American municipalities supplying their own citizens with electric current for lighting and power purposes.

The City of Winnipeg has built a hydro-electric plant which now develops 22,500 hp. and will eventually be increased to 100,000 hp., transmitting the current gener

ried 77 miles and distributing it to consumers at a maximum price of substantially 4c. per kw.-hr. Large consumers of power can obtain current at as low a rate as 1½c. per kw.-hr. One can imagine the popularity of the municipal plant with the citizens and the commercial interests of Winnipeg from the statement that no longer ago than 1905 the base rate per kw.-hr. for electric current furnished by a private company was 20c.

It is of interest to observe the financial situation of Winnipeg's great experiment in municipal electric generation and distribution. While the plant has the great advantage of generating electric-current from water power so that the item of fuel is eliminated, it has to stand the heavy capital cost due to the investment in the long-distance transmission line and also due to the fact that a large part of its plant has been constructed for the ultimate development of 100,000 hp. eventually to be furnished, while it has so far been operating with a maximum capacity of less than one-fourth this. Added to this is the necessity the plant has been under of building up and organizing its business to make it a going concern.

Notwithstanding these heavy handicaps, the Winnipeg plant for the fiscal year ending Apr. 30, 1914, showed a profit of something over $60,000, after paying all operating expenses and fixed charges. It has now reduced the accumulated deficit from the first two years of partial operation to only $82,000. The city is now enlarging its hydro-electric plant to develop 50,000 hp. If it can sell a fair proportion of this additional capacity, the enterprise should be placed on a very lucrative basis with the present rates to consumers.

Winnipeg experience is not without a certain bearing on the probabilities of success of the Cleveland municipal electric plant described in our issue of July 30 last. If Winnipeg can carry on this municipal plant at a profit, there seems good reason to believe that Cleveland can do the same. Reference to our description of the Cleveland plant will show that with the high fuel economy which the Cleveland plant is designed to secure, the cost of the coal burned per kilowatt of output is after all a very small proportion of the operating expenses and would be nearly offset, it is probable, by the much higher fixed charges on the Winnipeg plant due to the cost of the long transmission line and the water-power development.

The Harlem River Tunnel

The successful sinking last week of the last section of the tubes for the Harlem River Tunnel, on the line of the Lexington Avenue Subway, New York City, is an event of especial interest to engineers. As most of our readers are aware, this tunnel is being built by substantially the same process that was adopted in building the Michigan Central Tunnel under the Detroit River five years ago, and which was fully described in ENGINEERING NEWS at the time.

The process consists, in brief, of building successive sections of steel tubes somewhat larger in diameter than the completed tunnel, bracing them together, closing the ends of the tubes by temporary bulkheads so that they will float, sinking the sections one after the other in a trench dredged along the line of the completed tunnel, and filling with concrete, deposited under water through a tremie, the space below, around and over these steel tubes. The final step of the process is to pump out from the interior of the tubes the water which had been admitted when the tubes were sunk, and place a concrete lining inside.

The various details of the process were worked out with great care at Detroit, and the work was considered entirely successful from the point of view of practical construction. In building the Harlem River Tunnel, however, the contractors and engineers have had the advantage of the experience gained at Detroit and have facilitated the work by improvements in numerous particulars. The work at the Harlem River is easier than that at Detroit on some accounts as the depth of water is less and there is no current in the river at slack tides. There are, however, four parallel tunnels necessary for the Harlem River, as compared with the two at Detroit. The Harlem River Tunnel is much shorter than the Detroit tunnel, the width of the Harlem River between bulkheads being only 600 ft. Nevertheless, the successful completion of this second tunnel will give engineers renewed confidence in this system of constructing under-river tunnels.

One very important advantage of this system from the operating point of view over a tunnel driven with hydraulic shields is that the roof of the tunnel can be placed much closer to the bed of the river, thereby reducing the vertical distance which the train must descend in order to make the under-river crossing. The top of the Harlem River Tunnel structure is only 7 ft. lower than the original river bed.

Another consideration which appeals very strongly to engineers and contractors is the comparative security and certainty of the process. There is always more or less risk in driving tunnels under rivers with the hydraulic shield. The use of compressed air is almost invariably essential, and the pressures are apt to be carried so high that more or less cases of injury to workmen occur, which under the present Employers' Liability Laws mean a very heavy bill of expense to the contractor. The rapid work possible with the system is illustrated by the fact that while the Harlem River contract was signed July 23, 1912, the contractors, the Arthur McMullen & Hoff Co., have sunk the last section, as noted above, have encased in concrete the four sections previously sunk and are placing the inside lining; the contract date for completion is early in 1916; but the work is already more than two-thirds done.

When the system was first proposed for the Detroit tunnel, there was much skepticism as to the possible risk in sinking the successive sections of the tubes, and as to other features in connection with the work. Experience at Detroit and at the Harlem, however, has now fully established that the claims of the able engineers who originated and developed this process were sound; and where the local conditions are such as to favor its use it will probably be largely adopted in the future in preference to work with the hydraulic shield.

The Wood-Preserving Industry and the Supply of Creosote Oil

The sudden reduction in the supply of creosote oil from Europe as a result of the war is a matter of much importance to the wood-preserving industry. A special report upon the situation has just been prepared by

Clyde H. Teesdale, of the forest products laboratory at Madison, Wis., under the Department of Agriculture. According to Dr. Teesdale's figures, there are in the United States 94 wood-preserving plants, with an aggregate annual capacity of over 300,000,000 cu.ft. of timber. These plants actually treated 153,000,000 cu.ft. of timber in 1913. About two-thirds of this timber was treated with créosote, and most of the remainder with zinc chloride. In round numbers, these plants used a total of over 108,000,000 gal. of creosote oil, of which about 42,000,000 gal. were produced in the United States, and about 67,000,000 gal. were imported, principally from Germany and England. The supply from Germany has been entirely cut off, and for a time the English supply was also interrupted. It is likely, however, that the English supply will be reëstablished, and it may even be increased, since the English producers will lose a part of their market elsewhere.

On the assumption that the foreign supply of creosote to the United States will be seriously curtailed, Dr. Teesdale points out that the output of the timber-preserving works can be maintained either by adopting the zinc chloride instead of the creosote process of treatment, or by using the so called "empty-cell" process of creosoting, by which the consumption of creosote oil per cu.ft. is reduced to 5 to 7 lb. instead of 10 or 12 lb. It is also possible to use a mixture of creosote and zinc chloride, for which only about 3 lb. of creosote per cu.ft. of timber is required, and in fact, 8,000,000 cu.ft. of timber were treated by this combined process in 1913.

Other possibilities suggested by Dr. Teesdale are the use of creosote made from water-gas tar (most of which has hitherto been either burned or thrown away), the use of creosote and crude petroleum, the use of creosote made from wood tar, and the use of sodium fluoride. The last process has been experimented with successfully in Europe, and tests of ties treated with it are under way in the United States.

Another possible source of economy in creosote is reviewed by F. R. Church in an article published on another page of this issue, consisting in mixing refined tar with the creosote. This process, in fact, is already widely used.

Another factor which will tend to help out the wood-preserving situation is likely to be a falling off in the amount of timber creosoted. This will certainly happen should there be any large increase in the price of wood-preserving materials, but apart from that there will be probably in the coming year a comparative slackening in the demand for timber of all classes, on account of the falling off in construction work which is already apparent. Further, as we have already pointed out, the tendency of engineers will be to carry on their construction work at the lowest possible first cost, on account of the high interest rates likely to prevail, so that timber construction will be used in many cases without going to the expense of wood preservation.

The American railway-tie-preserving plants will probably continue with little slackening, as the work they are engaged on is necessary for regular railway maintenance. It is probable, however, that from English sources a considerable part of the deficit produced by the stoppage of German imports of creosote oil can be made up; and a falling off in the demand for preserving other classes of timber, with the use of some of the other processes suggested by Mr. Teesdale, will probably be sufficient to bring about an equilibrium in the industry.

Letters to the Editor

Graphite and Boiler Scale

Sir—Your issue of July 30, '14, contains an article on "Graphite Treatment for Boiler Scale" in which a good many claims are made for this method of removal of scale. The one which attracted my attention is that the graphite is noncorrosive and harmless. In this connection, I would like to refer you to the tests of boiler compounds made by the U. S. Government, under the direction of Lieut. Commander Frank Lyon. In the *Journal* of the American Society of Naval Engineers, November, 1911, p. 1080, he states: "Graphite is a scale remover for the same reason that hydrochloric acid is. That is, it corrodes the metal underneath the scale and frees the scale from the metallic surfaces." The tests referred to above extended over a period of years and should be authoratative.

The use of boiler compounds is at best a makeshift method and in permanent steam plants seems to be due to the false conception of many that eleventh hour cures are cheaper than other apparently more expensive installations for treating water outside the boiler. The waste of fuel is well known and the harmfulness of scale to the structural condition of the boiler does not need repetition here, but it seems a little strange that we have so little discussion of the scientific management of boilers. The ordinary boiler is designed to generate steam and is not intended to be used as a retort for chemical experiment.

P. M. LaBach.

Assistant Engineer, Chicago, Rock Island & Pacific Ry.

803 La Salle Station, Chicago, Aug. 30, 1914.

[Commander Lyon's tests were chemical-laboratory studies of certain chemical reagents which were being introduced to make boiler water alkaline or to render insoluble under heat the scale-forming constituents in feed water. The same experiments were applied to graphite though obviously it cannot act in either of these ways, being entirely a mechanical assistant. For instance, pieces of boiler plate were filed bright and immersed 2 in. for one and for 30 days in distilled water (200 c.c.) containing divers amounts of the various reagents—the latter being varied to find the anticorrosive concentrations. The tops of jars were left open for natural absorption of air and CO_2. Graphite not acting as a regeant, in spite of Commander Lyon's assertion that its nature is that of hydrochloric acid, yields no significant data under this experi-

[illegible]. Optimum conditions were present for stimulating corrosion of the iron samples. In a boiler there would prevail vastly different conditions, the lack of air, the changed chemical equilibria due to new temperature and pressure, the loss of initial bright iron surface to [illegible] contact with the carbon, etc., make it unsafe to prophesy from these studies as to what would happen in a boiler. Similar studies have "proved" that graphite and lampblack would be unmitigated evils in paint—but they continue to give at least fair protection where any oil paint would serve.

Commander Lyon made further accelerated and intensified tests of boiler compounds under more natural conditions in boiler tubes, but nothing was reported about graphite and indeed little vital information was to be expected if the action of graphite is mechanical and slow.

In regard to the general use of compounds in boilers referred to in the last paragraph of the above letter, we venture to suggest that it may be a question of economics. There is nothing holy about the inside of a boiler to forbid chemical action, and if it is cheaper to combine boiler and chemical tank it will be done. Experience seems to show that where there is present in the supply only 5 to 10 grains per gallon of scale-forming constituents, the separate water-treating plant can show no economy.—Ed.]

Bridges over the New York Barge Canal

Sir—In your issue of Sept. 10, 1914, you published a letter from Mr. John Reid, 17 Battery Place, New York City, with the heading "Boat Design Difficulties on the New York State Barge Canal."

In this letter, Mr. Reid criticizes J. A. Bensel, State Engineer and Surveyor, for not providing greater headroom under the fixed bridges that have been constructed over the Barge Canal under the authority given to him principally by Chapter 147, Laws of 1903.

It has been the privilege of the writer to serve under Mr. Bensel for the past three years, and I feel it my duty to explain to Mr. Reid that the above mentioned chapter provides: "All fixed bridges and lift bridges when raised shall give a clear passageway of not less than 15½ ft. between the bridge and the water at its highest ordinary navigable stage."

The funds available for this work do not provide a sufficient amount to place as many fixed bridges as are necessary. The cost of [illegible] bridges is therefore prohibitive.

The above mentioned law also provides a bottom width of 75 ft. and a depth of channel of 12 ft., where a new location has been made or where the old location was enlarged. These dimensions, however, apply only to the land line and affect about [illegible] of the total length of canal, the remaining part of the line being located in several river or lake channels where a width of channel of 200 ft. or more will be available for navigation.

The State of New York has authorized an expenditure of [illegible] for the improvement of the Erie, Oswego, [illegible] and Cayuga Canals, to accommodate barges of 1000 tons capacity. The canal that is now nearing completion under the able leadership of the present State Engineer and Surveyor will accommodate vessels of about 2000 tons capacity and it seems to me that this fact should be better known and appreciated by the public in general and by all naval architects in particular.

W. H. YATES.

Albany, N. Y., Sept. 17, 1914.

Lessons from Difficulties in Initial Operation of High-Tension Transmission Lines

Sir—Referring to the article by F. G. Allen on "Difficulties in Initial Operation of 110,000-Volt Transmission Line," in your issue of Aug. 20, the author is entitled to the thanks of the profession for furnishing information on details too frequently omitted from the published accounts of such construction. It would be of great assistance to the designers of transmission lines if more publicity were given to the actual results obtained in service.

Although the relative value of some of the details of construction is difficult to ascertain, such information is very greatly to be desired. A detail which gives entire satisfaction in service is well worth an excess of cost over that of a somewhat unsatisfactory detail. This feature was evidently given consideration, since it is stated by the author that two ground wires were used, and that the structures were heavier than many of those heretofore installed. Further, it would appear, from the lack of insulator failures, that the two ground wires have presumably given adequate protection to the line. However, it would be of interest to know whether, other conditions being equal, the line with two ground wires has had less failures during a given period than neighboring lines with but one ground wire.

In case the power conductors are copper wires, with, in most localities, an indefinitely long life, it is possible that a greater ultimate benefit would be obtained for about the same original expenditure if one copper cable or a copper-covered cable were used as a ground wire, instead of, as has sometimes been the case, two galvanized steel cables.

It was probably not so intended by the author, but the inference might be made that suspension-type insulators were, per se, more desirable than pin insulators for the telephone wires. It would seem that the telephone wires could have been carried successfully on high-tension pin insulators, and by transposing them in every span, or in every few spans, that the inductive troubles should have been considerably reduced.

R. D. COOMBS,
Consulting Engineer.

[illegible] Church St., New York City, Aug. 21, 1914.

Sir—Answering R. D. Coombs' letter of Aug. 21, we beg to advise as follows:

It would hardly be logical to state that two ground wires afford better protection than one wire, as there is no other high-tension line paralleling the [illegible] line, and to compare the results of operation of this line with some other line would not be proper because of different local conditions. It might be interesting to note, however, that the [illegible] line has been struck by lightning three times, and the lightning in each case tripped the

insulators of their skirts, but when voltage was again placed on the line, the insulators stood up O. K. without puncturing. This would lead one to believe that the ground wires are not a perfect protection. However, we do not feel that we have compiled, as yet, sufficient data to speak of the absolute efficiency of overhead ground wires.

As to the question of using copper-clad cable for ground wires, or one copper-clad cable instead of two steel ground wires, such construction has been contemplated in view of the fact that the life of the ground wire should be the equal of that of the power conductors. On the other hand, the steel in the towers is only galvanized. There is no question about the life of the ordinary steel ground wire being greater than that of the towers themselves, and it is probable that during the life of any steel towers now constructed, more definite information will have been learned regarding the merits of overhead ground wires for lightning protection, the result of which may be the discontinuance of their use.

As to the last paragraph of Mr. Coombs' letter regarding the use of suspension insulators on the telephone lines, the suspension type of insulator was decided upon instead of a higher-voltage pin-type because the method of construction made it easier to make a change of this kind, and the additional advantage was obtained of being easily able to add a second suspension insulator should it be necessary to further raise the insulation of the line.

The telephone lines are transposed at each and every tower, but this only keeps down the voltage between the two wires and prevents unbalanced potential, and does not reduce the voltage induced between the telephone wires and the ground by the voltage on the power conductors. This induced voltage to ground under normal operating conditions is about 5600 volts, but is considerably reduced by the installation of drainage coils, specially designed for the purpose, between the telephone lines and ground. Tests made on the telephone lines under special conditions showed an induced voltage to ground of some 18,000 volts, and under surges set up by lightning or switching on the proper conductors, insulators on the telephone lines which were tested to 70,000 volts have punctured, as the drainage coils do not protect the equipment from steep-front oscillating waves.

CHAS. O. LENZ, Chief Engineer.
BY FRANK G. ALLEN, Secretary.

Georgia Ry. & Power Co.,
71 Broadway, New York City, Sept. 2, 1914.

NOTES AND QUERIES

Track Layouts at Stations (Correction)—In this article in our issue of July 9 there was an error in the 14th line of second column, page 57. Tracks (A) and (C) are kept clear, and not (A) and (B), as stated.

In the article on the "Irrigation Operations of Imperial Water Co. No. 1 for the Year 1913," published in our issue of Sept. 3, 1914, p. 495, the full address of Ray S. Carberry, Superintendent of the company, was not given. As many of our readers may be interested in securing from Mr. Carberry a copy of his complete report, we would advise that he is located at Imperial, Calif.

The Mountain Parks of Denver, Colo., are to be increased by the addition of 30,040 acres ceded to the city by the Federal government without cost to the city by a recent act of Congress which has just been signed by President Wilson.

Another Municipal Electric Plant Supplying Lighting Current at 3 cents per Kw.-Hr.

BY R. A. SARA*

In ENGINEERING NEWS, July 30, 1914, an article on "Cleveland's New Municipal Electric Plant," states that

Cleveland is the only city in the United States or anywhere else, for that matter, as far as we are aware, where a municipal electric plant furnishes electric current at a maximum rate of 3c. per kw.-hr.

Charles F. Roland, Industrial Commissioner of Winnipeg, population 210,000, has asked me to forward details of the Winnipeg municipal plant which, since October, 1911, has been selling electric current in Winnipeg at a maximum net rate of 3c. per kw.-hr. Large consumers buy power as low as ½c. net and commercial lighting is as low as 1¼c. net. The rate system may be outlined as follows:

SCHEDULE B: Residence Lighting, 3⅓c. per kw.-hr., subject to a net minimum monthly payment of 50c. per meter.

The city allows a discount of 10% on all bills paid within ten days.

SCHEDULE A: Commercial lighting, 3⅓c. per kw.-hr., subject to a net minimum monthly payment of $1 per kw. of total connected load, but in no case less than $1 net per month per meter. Prompt payment discounts: One year contract, 10%; three-year contract, 15%; five-year contract, 20%. Wholesale discounts on gross bills over $25 per month:

	Per cent. discount
For the first $25	None
For the second $25	20
For the next $50	25
For the next $50	30
For the next $50	35
For the next $50	40
From $250 to $500	50
Excess over $500	60

SCHEDULE E: Heating, 1c. per kw.-hr., subject to a net minimum monthly payment of 75c. per kw. total connected load, but in no case less than 75c. net per month per meter. (Where connected load is greatly in excess of maximum demand the city will install an automatic cutoff and base the monthly minimum charge on specified load at which the cutoff is set.)

Prompt payment discount, one-year contract 10%.

SCHEDULE C: Alternating-current power.

	Cents per kw.-hr.
First 50 hours per month use of total connected load	3⅓
Next 50 hours per month use of total connected load	2.5
Next 50 hours per month use of total connected load	1.9
Next 50 hours per month use of total connected load	1.4
Next 50 hours per month use of total connected load	1.1
Excess over 250 hours per month use of total connected load	0.8

Subject to minimum monthly payment of 75c. per hp. of total connected load but in no case less than $1 net per month per meter. Prompt-payment discounts: One-year contract, 10%; three-year contract, 15%; five-year contract, 20%.

Wholesale discounts apply on gross bills of over $100 per month.

	Per cent. discount
For the first $100	None
For the second $100	10
For the third $100	20
For the fourth $100	30
For the fifth $100	40
From $500 to $1000	50
Excess over $1000	60

SCHEDULE F. Direct-current power.

	Cents per kw.-hr.
First 50 hours' use per month of total connected load	3⅓
Next 50 hours' use per month of total connected load	2.5
Next 50 hours' use per month of total connected load	1.9
Next 50 hours' use per month of total connected load	1.4
Next 50 hours' use per month of total connected load	1.1
Excess over 250 hours' use per month of total connected load	0.8

*Sales Manager, City Light and Power Department, Winnipeg, Man.

[illegible] to a [illegible] monthly payment of [illegible] per hp. of [illegible] load [illegible] $1 net per month per [illegible].

Prompt payment discounts [illegible] contract [illegible] contract [illegible]

Schedule E applies where separate circuits are provided. The low rate, [illegible] ct., has encouraged electric cooking to such an extent that over 1000 electric stoves are in use.

The effect of the municipal service on electric rates in Winnipeg is thus shown:

[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]

Construction commenced in 1909 and operation in October, 1911. The generating station is situated at Point du Bois on the Winnipeg River, 77 miles from Winnipeg, where a 46-ft. head is available.* The total power available at the site is 100,000 hp. The original development included dams, forebay, head-gates, etc., for the full amount, but only 22,500 hp. capacity was installed. This is now being increased to 50,000 hp., and the remainder may be developed at any time by extending the power-house building and installing water-wheels, generators and transformers.

Current is transmitted to Winnipeg at 60,000 volts over a double-circuit aluminum-conductor steel-tower transmission line situated on a 100-ft. right-of-way. It is stepped down at the terminal receiving station to 12,000 volts and distributed underground to the substations located conveniently around the city.

The expenditure on the original development was as follows:

(1) Hydro-electric plant and generating station	$2,336,19[illegible] 60
(2) Transmission line and terminal receiving station	1,390,[illegible] 30
(3) Distributing system	2,012,7[illegible] 79
Total	$5,739,[illegible] 09

This has since been increased to $6,721,372.58 (April 30, 1914) by additions to the plant and extensions of the distribution system. Progress made may be summarized in part as follows:

Period	[illegible]	Kw.-hr. generated	Gross earnings	Net profit or loss
[illegible]	[illegible]	[illegible]		$[illegible] loss
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Total	[illegible]			[illegible]

The plant was operated at a loss during the first year and a half because during that period the business connected up was not sufficient, at the rates prevailing, to pay all charges although 21,791 meters were connected at that time. The present low rates were made at the commencement of operation as it was realized that the lower the rates, consistent with cost, the quicker the load would be secured. It is safe to say that the deficit will be entirely wiped out of profits early in 1915.

The accounts are kept according to forms prescribed by the Public Utility Commission of the Province of Manitoba, which periodically audits the books and stipulates what provision shall be made for depreciation, etc. The financial statements have been approved by this Commission.

*Described in "Engineering News," [illegible] 1914.

Annual Convention of the National Paving Brick Manufacturers Association; Inspection Tour of Brick Roads*

Two days of the annual convention of the National Paving Brick Manufacturers Association, held in Buffalo, Sept. 9-11, were devoted to automobile inspection tours over brick roads, both completed and in various stages of construction. As guests on these trips the Association had many city and highway engineers and professors of civil engineering from the Eastern States, where as a general thing brick country roads are rather the exception.

On leaving Buffalo to the southwest many brick-paved streets were inspected which had several years' service to their credit. From city streets the trip was continued on over brick country roads almost without a break.

Having seen several brick roads three and four years old, the party disembarked at State Road No. 5407, where a brick pavement 5.92 miles long is in the process of construction. This road is a good example of the highest class of New York State road work. This piece of construction includes several thousand feet of new alignment. The pavement is made 16 ft. wide on a 5-in. (minimum 5-in., 7-in. at center) concrete base, mixed 1:2½:5. The contractor is the Louis H. Gipp Construction Co., of Buffalo, and the brick used are of the wire-cut lug variety.

The accompanying illustrations show all phases of the pavement work but laying and rolling the brick. After the subgrade is prepared and rolled the stone and sand for the concrete are piled directly on it. Just the right quantities are distributed either side of the paver so

*For report of annual meeting see "Engineering News," Sept. 17, 1914, p. 600.

Construction Views of a First-Class Brick Road, New York State Highway Department. Hamburg, N. Y.

that the passage of the mixer uses up all the material, leaving the subgrade ready to receive the concrete.

The forms to support the concrete base and edging* consist of 10-in. channels, properly aligned and held in place by ½-in. round iron rods driven through holes in the flanges about every 3 ft. Between these 10-in. channels the concrete foundation is laid 5 in. deep, and then a 2x6-in. plank is laid on edge on the base, separated from the channel by 6-in. wood struts, which are knocked out as the work of filling progresses (Fig. 3). The plank and channel are held together by strap irons or brackets, which are quickly lifted off and the forms removed as soon as the concrete has sufficiently set.

Figs. 2 and 4 show the concreting in progress. After the base is struck off and given its proper crown by means of a board screed or float, it is smoothed with the implement shown in Fig. 5, which is a device worked up by the contractor. This consists of a sheet-iron disk, about 18 in. in diameter, with upturned or beaded edge. To the disk, about halfway between its center and its edge, is fastened a handle 8 or 10 ft. long by means of a universal joint. On the same diameter of the disk opposite the handle is a counterweight. Pushing the disk back and forth gives it a revolving as well as a sliding motion, which answers admirably for troweling.

Longitudinal expansion joints along the edging are provided, but no transverse joints. Each longitudinal expansion joint is 1 in. wide and is made by placing alongside each edging, wood strips with metal wedge pieces dropped over the tops of the boards, and between the board and the edging, every 3 ft.

Fig. 6 shows a steel sand spreader for smoothing and crowning the sand cushion; and Fig. 7 shows the first filling of the joints with a very wet grout, after which the pavement is gone over with a thicker grout, having the consistency of cream (Fig. 8), which is spread and worked into the joints with squeegees.

After the grouting has been completed and the joints filled flush with the tops of the brick and the grout sufficiently hardened so that the sand will not absorb moisture from the grout, a ½-in. layer of sand or gravel is spread over the pavement and kept moist for at least 10 days, to insure a proper curing of the grout. The bituminous filler for expansion joints is placed as soon as the grout has set, and within 36 hr. of the time when the grout was applied.

Leaving this piece of work the inspection party continued to Hamburg, where an opportunity was given to examine the [illegible] effects of transverse expansion joints in a brick pavement built in 1910. Further on, the resurfacing of a water-bound macadam road, built in 1907, was in progress. Here wire-cut-lug brick are being laid on a 5-in. concrete base, which is built on top of the old macadam.

The first day's trip was completed after a luncheon at the Roycroft Inn, East Aurora, by returning to Buffalo over a different route, which presented several excellent examples of recent brick-road construction.

The second day's trip was to the north, through Delaware Ave., Buffalo, to Niagara Falls. On this trip, also, much of the traveling was over brick pavements which had been in place from a few months to 20 years. In one continuous strip on the famous Niagara Boulevard is 17 miles of brick road, from the city line of Buffalo to the city line of Niagara Falls. This road cost $375,000 and is a splendid example of both repressed and wire-cut-lug brick pavement.

From the city of Niagara Falls the party continued to Lewiston and old Fort Niagara, returning to the International Hotel at Niagara Falls for lunch. Much of this road follows the famous old portage road of the French and Indian War period and is replete with historical associations. Long stretches of this road are also brick paved.

While the above itinerary probably would contain little new to city and highway engineers of the Middle West, where brick roads and street pavements have long been so favorably known, it was quite an education to many of the Eastern visitors. Buffalo and vicinity is probably as far east as brick country roads have yet been built on any very extensive scale.

The Creosote Oil Situation and the Treatment of Crossties*

By S. R. Church†

Statistics compiled by the Forest Service of the United States Department of Agriculture in cooperation with the American Wood Preservers' Association, show that approximately 40 million crossties were treated during 1913, an increase of about 20% over 1912, and an increase of 100% over 1908. Of these, approximately 25 million were treated with creosote oil. Those thus treated probably required between 60,000,000 and 70,000,000 gal. of oil, or approximately two-thirds of the total creosote oil consumed during 1913.

The production of creosote oil in the United States for 1913 was, roughly, 40,000,000 gal., or less than 40% of the total consumption; and the balance of the oil, over 66,000,000 gal., was imported from Europe, principally from Germany and England. It is evident that no imports of oil from Germany can be expected for some time, particularly as a specific embargo has been laid upon such shipments by the German Government, and shipments from England are by no means to be counted upon.

This situation lends peculiar significance to the discussion on wood preservation that occurred at the meeting of the American Railway Engineering Association, when the report of the Committee on Wood Preservation was presented. This committee has realized for some time that the supply of high-grade creosote oil such as they have recommended and specified as "No. 1 Creosote Oil" was limited and inadequate, and they have for a number of years been investigating the merits of the use of refined coal tar in creosote oil.

Prior to the publication of this report, definite information was difficult to obtain, although it was recognized that many roads had adopted this practice. It was estimated by von Schrenk and Kammerer‡ that 40% of all the creosote oil used at present in the United States was a combination of coal tar and distillate oil. In addition

*This statement of the war's effect on the supply, with special reference to the treatment of railway crossties, was furnished by the Barrett Manufacturing Co. at our request.—Ed.

†Manager, Research Department, Barrett Manufacturing Co., 17 Battery Place, New York City.

‡"Use of Refined Coal Tar in the Creosoting Industry," Proc. A. R. E. A., 191[illegible]

to this summary of von Schrenk and Kammerer, a report was presented and printed in the *Proceedings* of the American Railway Engineering Association, p. 1074, by the writer, on tests made in December, 1913, at the plant of the Pittsburgh Wood Preserving Co. In these tests a direct comparison was made on eight different kinds of wood, of ordinary coal-tar creosote oil of No. 2 grade and a special grade of creosote oil containing filtered coal tar, prepared to meet the following specification:

The oil shall be a pure coal-tar product, containing no crude tar.
Water shall not exceed 2%.
Specific gravity at 38° C. 1.06 to 1.10.
Insoluble in hot benzol, not over 2%.
Distillation by standard method:
Not more than 1% at 170° C.;
" " " 5% " 210° C.;
" " " 30% " 235° C.;
" less " 40 nor more than 60% at 300° C.;
" " " 60% at 355° C.
Viscosity at 100° C., not more than 25 sec. for 100 c.c

Analyses of average samples of the oils used throughout the tests were given as follows:

	Regular Oil	Special Oil
Specific gravity at 38° C.	1.049	1.078
Water, per cent	0.30	0.30
Free carbon, per cent	0.31	1.00
Viscosity (100 c.c. Engler)		
at 60° C. (140° F.) sec.	25.5	28.6
at 100° C. (212° F.) sec.	23.8	24.4
Retort distillation:		
Total to 170° C., per cent	0.0	0.0
" " 200° "	1.7	1.5
" " 210° "	4.8	4.3

From the results of these tests it was determined that equally good penetration could be obtained with the special oil as with the regular oil under the same conditions of treatment, both by full-cell and empty-cell processes; the only difference was that the oil in the cylinder was maintained at an average of 15 to 20° higher during the treatment with the special oil.

If this discussion was pertinent and interesting to the railroads when presented, it certainly becomes of much greater importance in the light of the present shortage of creosote oil. It is recognized that the oil used in the Pittsburgh experiments contained approximately 30% of filtered coal tar, yet. owing to the care with which it was prepared and the elimination of free carbon by filtration, the oil was scarcely more viscous at the temperature of treatment than a straight distillate oil, and not only penetrated the ties equally well, but left a perfectly dry and unobjectionable surface of the timber employed.

These results could not, of course, be duplicated by indiscriminately mixing crude tar with creosote oil; but as Earl Stimson, Chairman of the Committee on Wood Preservation, indicated in presenting his report, the committee may be expected before very long to prepare definite specifications for such a product, under which the railways may use such oil with economy.

In view of the urgency of the present situation, and particularly in view of the natural increase in the price of high-grade creosote oil, the railways operating treating plants might well consider anticipating such a recommendation from the committee, and we have no doubt that the committee's experts, such as Dr. von Schrenk and Mr. Sterling, would be glad to recommend tentative specifications which might safely be used for all the work the roads might have.

Even should all the railways adopt this grade of oil there would still be a shortage; but conditions would certainly be very much relieved by such practice.

Sidelights on the Salem Conflagration *

The burning of 1600 buildings in Salem, Mass., in 13 hr. (June 25-26), devastating 253 acres of the business district at a loss of $14,000,000, is too important and too typical of like possibilities in other American cities to be passed over with a mere description of the damage, published immediately after the fire. No investigation was needed to discover that frame buildings are a continual invitation for this sort of disaster. One of the important recommendations in the bulletin is that the use of wood shingles be prohibilted in all districts of a city.

Knowledge that the old wrought-iron and cement water mains were weak restricted the manipulation of the water-supply, although these mains did not burst until after the fire had spent its force. The abundant water-supplies of Peabody, Danvers and Beverly were gingerly tied into the Salem system, resulting in a hydrant pressure of 10 to 20 lb.

It would seem that the long campaign for standard fire hose and hydrant connections throughout the country, so logically based, would have met success ere now; but, as usual, in a conflagration of this character, the fire apparatus of some of the surrounding towns was rendered impotent through inability to connect to the water system.

The gasoline-driven fire engine was shown to be more mobile than the horse-drawn apparatus, and to be able to carry sufficient fuel for such a demand, instead of having to requisition wood fences and box boards.

The second recommendation made in this bulletin is for the establishment of a modern and reliable water-supply under adequate pressure, and well distributed post hydrants with standard connections.

The final recommendation bears upon the out-of-date fire department of Salem, which maintained no adequate inspection bureau. It states the need for proper municipal housekeeping under the administration of a commissioner or a fire chief possessing modern ideas and with authority to maintain cleanliness; regulating the storage and use of inflammables; and compelling the proper automatic fire protection of all buildings endangering the public safety.

A Flood from a 7-In. Rainfall at Kansas City†

A local rainfall of 7 in. in 10 hours on Sept. 8 caused heavy damage at Kansas City, Mo. The storm sewers were entirely inadequate to handle the rainfall and many basements were flooded. Far greater damage, however, was done in Rosedale, Kan., and Armourdale, Mo., which were inundated by the rise in Turkey Creek. The damage is estimated at $1,500,000.

The drainage area of upper Turkey Creek comprises about 14,000 acres; lower Turkey Creek has a drainage area of 1088 acres. The discharge of Turkey Creek at flood stage is about 28,000 sec.ft. It is practically the only outlet for the district and overflows at a low stage

*Notes from a recent bulletin of the National Fire Protection Association, 87 Milk St., Boston, Mass., by Franklin H. Wentworth. The bulletin may be purchased from the Association for 10c. per copy.

†Information furnished by Murray & Hamilton, Consulting Engineers, 920 Walnut St., Kansas City, Mo.

because the channel is small and crooked and has been further restricted by the construction of overhanging buildings resting on piles, and by the erection of numerous low, narrow railway bridges. Probably four-fifths of its drainage area is steep rocky hillsides.

Some of the bridges crossing the creek are of steel and some of reinforced concrete, but many are timber trestles, with bents spaced 16 ft. c. to c., which prevents the passage of any driftwood coming down the creek at flood stage. Most of the buildings which encroach upon the creek channel were carried away by the first rush of water or collapsed when their supports were washed out, adding to the wreckage in the channel and tending to dam it. Lumber from a lumber yard and wood poles from a supply yard of the Kansas Home Telephone Co. were added to the wreckage in the creek.

At the Terminal yards, just east of the Kaw River, the miscellaneous drift piled up against the bridges crossing the stream at that point, carrying away some and shifting others out of alignment.

The wide timber trestle at the mouth of Turkey Creek, which carried the Santa Fé feed tracks to the stock yards, was wrecked, leaving only a couple of tracks spanning a gap approximately 150 ft. wide.

Neither the machinery nor the settling basin of the pumping station, which lies in a bend of Turkey Creek and back about 1000 ft. from the Kaw River, was damaged.

The levees also were damaged. The first break occurred about 400 ft. upstream from the Kansas Belt bridge, and was 110 ft. across and about 35 ft. deep, extending into the Santa Fe yards approximately 200 ft. This break occurred where the Santa Fe had placed a 3-ft. storm sewer through the levee, and had evidently not tamped the back fill properly. Several strings of box cars standing on the track at this hole were washed downstream.

A hole, about 60 ft. wide and 30 ft. deep, was washed at each side of an abutment of the Belt bridge, which is $4\frac{1}{2}$ ft. lower than the levee grade. About 200 ft. downstream from the bridge another break occurred, where a 12-in. sewer extended through the levee. The hole washed here was about 200 ft. wide and 35 ft. deep. Several cattle cars were washed away and the cattle drowned.

F. H. McNeel, Chief Engineer of the Kaw Valley Drainage District, estimates that more than 35,000 cu.yd. of earth will be required to repair the damaged levee, exclusive of the filling required for the holes back of the levee. The levee was not designed to withstand any [illegible] from the rear.

The Kaw River rose more than 10 ft., and had an estimated velocity of 7 ft. per sec. All railways from the southwest entering Kansas City were tied up, except the Chicago, Milwaukee & St. Paul Ry., and the Strang Electric line. The Chicago, Burlington & Quincy R.R., and the Atchison, Topeka & Santa Fe Ry., both had several miles of track washed out about Kansas City.

Turkey Creek has long been subject to destructive floods. There are three solutions to the problem: (1) Straightening the channel and diking along the creek; (2) constructing a reservoir for the excess water; (3) re-routing the creek to a cut-off at the lower end of the upper district, through Gladstone Heights, and extending [illegible] Creek sewer to the Kaw River, and diverting the lower Turkey Creek basin into this sewer by means of a large storm sewer.

The crookedness of the present channel, the value of the adjoining land, the necessity of raising the Terminal yard through which the creek flows, and the lack of a site for a reservoir, make the first two solutions impracticable. The third was suggested by L. R. Ash, a former City Engineer of Kansas City, who recommended the diverting of a part of Turkey Creek through a tunnel which emptied into the Kaw River, approximately 100 ft. south, or upstream from the Fifth St. Bridge. The distance from the mouth of the natural course of the creek, measured up the river, is 6200 ft.; measured down along the natural course of Turkey Creek, it is 10,000 ft.

NEWS NOTES

Washouts at Eagle, Stoughton, Hanover, Broadhead and Gratiot, Wis., from heavy rains on Sept. 14 interrupted traffic on the Chicago, Milwaukee & St. Paul R.R.

A Scaffolding Collapse in the Cross Keys Moving Picture Theatre, under construction in Philadelphia, Penn., on Sept. 9, injured five workmen who fell to the basement, 65 ft. below.

Lightning Struck Steel Oil Tanks near Ringling, Okla., recently. The subsequent fire destroyed 20 tanks, of which seven were of 55,000-bbl. capacity. About 600,000 bbl. of crude oil were stored in the tanks, accumulated in great part since the European war.

A Water-Supply Conduit Failed in a Los Angeles water tunnel near Hollywood, Calif., on Sept. 8, killing one workman and injuring another. The accident occurred on the line between the San Fernando Valley at the lower end of the Los Angeles Aqueduct, and Hollywood, where the water-supply enters Los Angeles.

Broken Axle Caused Collapse of a Steel Railway Bridge—A train of six cars, traveling at high speed, was derailed by the breaking of an axle, at a steel bridge over Crum Creek, west of Woodlyn, Penn., on the Baltimore & Ohio R.R. on Sept. 21. The train plunged through the bridge. One passenger was seriously injured.

The Collapse of a Concrete Span of the Twelfth St. Viaduct being constructed over Mill Creek Valley, St. Louis, Mo., on Sept. 13, injured the superintendent of construction, two steel workers and two concrete workers. It is stated that the forms were being removed when the accident occurred. The collapsed section was [illegible] ft. long and it fell [illegible] ft.

A Freight Train Smashed a Street Car at a grade crossing five miles from Memphis, Tenn., on Sept. 1[illegible], killing nine persons and injuring 1[illegible] others. Just preceding the accident a freight train had cleared the street railway tracks and the crew of the car failed to observe that another train was following. The street car struck was being drawn by another car which escaped damage.

Air-Brake Trouble on a Train in the Phoenixville Tunnel of the Philadelphia & Reading Ry., near Philadelphia, on Sept. 21, stalled the train and filled the tunnel with gas and smoke. The enginemen and conductor of the Pottsville express were killed and [illegible] passengers were overcome by the gas. The train had been stopped about [illegible] yd. inside the tunnel on account of striking a workman on the tracks near the portal.

Collision with a Carload of Slag [illegible] caused the death of [illegible] persons and the injury of [illegible] on a Queen & Crescent passenger train, near Livingston, Ala., on Sept. 18. The engineman, who was killed, is said to have [illegible] the [illegible] signal at the block just preceding the [illegible] where the wreck occurred. It is thought that the switch had been tampered with. The train, composed of six [illegible], [illegible] day coaches, mail, baggage and express cars, left [illegible] shortly after midnight last night, a half hour late.

Two Sections of a Large Water Main Broke, in [illegible], Ohio, on Sept. [illegible], badly damaging the pavement and cutting off the water supply in the district for at least 12 hr. and flooding cellars and the Pennsylvania R.R. tracks in the vicinity. Superintendent [illegible] stated that three or four days would be required to repair the damage. The situation was said to be further complicated by the fact that only one

f the reservoirs in Eden Park was available. Three reserve pumps were started almost as s en as the accident occurred and were of great assistance.

A Washout Caused a Severe Train Wreck on the St. Louis & San Francisco R.R., 2 miles west of Lebanon, Mo., on Sept. 15; 21 persons were killed and 18 injured. Heavy rains of the preceding week had swollen the streams in this vicinity to flood stages. In the heavy rain of the night before the accident, a 12-ft. fill crossing a gulley, on a curve, was washed out. Although it is stated that the train was not moving rapidly, it could not be stopped in time to save the locomotive, chair car and smoker from going over the structure. The four sleeping cars remained on the track.

Steamship Damaged by Fire While at Dock—A fire was discovered in the forward part of the Mall ry steamship "Neuces," at 8 p.m., Sept. 18, at Pier 9 of the Tietj n and Lang Dry Dock Co., Hoboken, N. J. Considerable wood was used in some reconstruction work involving th addition of a number of staterooms and it was this woodwork which burned fiercely. There had been no fire in the ship engine room for several days, and it is believed that the blaze started in the reconstructed section. Tugs towed adjacent ships beyond the danger zone. Water was poured into the ship until she settled several feet. The fire, however, was gotten under control. The "Neuces" was built in 1887.

A Ship Collision on the St. Lawrence River caused the loss of 14 persons on the Government steamer "Montmagny," which was rammed by the Black Diamond collier "Lingan," at 5 a.m., Sept. 18, in a fog at the Beaujeu Banks, 1 mi. below Crane Island, and 26 mi. from Quebec. The "Montmagny" sank in 3 min. The "Lingan" backed off leaking badly. She is of the same type as the "Storstad," which sank the "Empress of Ireland" in the St. Lawrence last spring. She is of 4338 tons burden and was laden for Montreal. The sunken vessel is a steel, twin-screw steamer of 1269 registered tonnage, owned by the Canadian Government and employed by the Department of Marine and Fisheries. She was built in 1909.

A Heavy Explosion in a 6-ft. Brick Sewer, on East 42d St., New York City, at 5:30 p.m., Sept. 22, blew off some 30 manhole covers, injuring fiv persons and causing damage to several b ildings by breaking windows. The heaviest explosion appeared to be in the vicinity of Third Ave., where three manhole frames and several square feet of the surrounding pavement were demolished. A trolley car standing near one of these manholes was badly splintered and three or four passengers injured. The manhole frames in at least two instances were entirely wrecked, and sections of asphalt pavement several feet square were thrown a number of feet away. The manholes are between the trolley tracks and next to the rails granite blocks were laid; these were thrown considerable distance and broke windows in nearby buildings. Flames followed the explosion, showing considerable quantities of gas. The sewer at this point is a brick-lined rock tunnel and to this fact is attributed the little apparent damage to the street. The bricklined manholes appeared badly cracked but at this writing an examination of the interior of the sewer had not been made. There were heavy explosions in this same sewer last July and again in August.

Divers Working on the "Empress of Ireland," in the St. Lawrence River, have recovered all the silver bullion and mails on the vessel. The mail sacks were sent to the Post Office Department, Ottawa. Diving work on this job has closed for the season.

The Pratt Bequest to the Massachusetts Institute of Technology, providing $750,000 for a school of naval architecture, practically has been allowed by the Massachusetts Supreme Court in indicating the way to be followed out of the technicalities upon which attempts to break the will were based.

The Three-Cent Fare Ordinance imposed by the city of Toledo on the Toled S reet-railway system (and resulting in a controversy noted in "Engineering News," April 16, 1914, p. 868) was d clared confiscatory and unconstitutional on Sept. 12, by Judge J. M. Killits in the U. S. Circuit Court. The city's expert accountants are reported to have admitted reduction of earnings below reasonable return. Pending n gotiations the 3c. rate will prevail during "workingmen's" hours, according to an earlier agreement.

The Substitute River and Harbor Appropriation Bill, passed by the Senate on Sept. 22, provides a lump sum of $20,-000,000 "to be expend d under the direction of the Secretary of War and the supervision of the Chief of Engineers for the preservation and maintenance of existing riv r and harbor works and for the prosecution of such projects heretofore authorized as may be most desirable in the interests of commerce and navigation and most economical and advantageous in the execution of the work."

The allotments to various works from the appropriations are to be made by the Secretary of War under direction of the Chief of Engineers and the amount allotted to work on the Mississippi below Cairo is to be expended under direction of the Mississippi River Commission.

Statistics of Accidents to Workmen in Ohio are made public by the Ohio Industrial Commission, reporting on the accident claims filed under the State Workm n's Compensation Act for the period from Mar. 1, 1912, to Dec 31, 1913. Referring to the number of employees covered by state insurance, 110,000 in number, the report states that during the year 1913, 13 industrial accidents occurred for every 100 employees exposed to risk, or one employee was injured for every eight exposed to risk. Of course, most of these were minor injuries, for which medical and hospital expenses are paid, but no compensation is allowed unless a loss of time of more than sev n days ccurs. During the year, four employees out of every 100 insured received compensation for loss of time on account of accid nts, or one in every 25 exposed to risk.

During the year, 16,544 accident claims were filed, of which 13,408 were allowed and 938 were disallowed, while 2198 were pending at the close of the year. Of the claims allowed, 40 were death claims, 2 were for permanent total disability, 302 were for permanent partial disability, 4787 were for temporary disability involving loss of time of more than seven days; 8277, or nearly two-thirds of the whole number, involved loss of time of less than seven days, and only medical and hospital expenses, not to exceed $200, were allowed. The total compensation allowed amounted to $378,-000, of which nearly $100,000 was for death benefits. The average death benefit awarded was $2510.

The Negative-Head Mechanical Water-Filter Patent Decision against Harrisburg, Penn., noted on p. 528 of our issue of Sept. 11, 1913, has been reversed by the United States Circuit Court of Appeals of the Third Circuit. The court declares that Harrisburg has not infringed either of the two patents involved: No. 644,137, dated Feb. 27, 1900, and Reissue No. 11,672, dated Jan. 28, 1898 (original No. 546,738, dated Sept. 24, 1895.) In its summing up the court said:

> However, it is probably enough to say that (at the best) the evidence in behalf of the company leaves us in much uncertainty whether the theories of the patents are sound. We do not feel bound to go the length of declaring the patents invalid—the re-issue patent, indeed, has already expired, leaving the patentee only a claim for royalties—but we are prepared to say that while the subject is so surrounded by uncertainty the company cannot reasonably object to the application of a test that tries the Harrisburg filters by the theories of the patents.

The suit was originally brought in 1908 by the New York Continental Jewell Filtration Co., 15 Broad St., New York City. There appeared as expert engineers in behalf of Harrisburg, James H. Fuertes, Geo. W. Fuller and Allen Hazen, of New York City, and in behalf of the plaintiff filter company Geo. A. Johnson, of New York City, and Profs. Wm. P. Mason and James M. Caird, of Troy, N. Y. Various filter-manufacturing companies (licensees of the plaintiff) assisted in the suit against Harrisburg and that city was aided by a number of water-works having mechanical filter plants, as stated in more detail in our issue of Sept. 11, 1913.

PERSONALS

Mr. W. D. Jones, formerly of Pittsburgh, Penn., is now Designer for the Broken Hill Proprietary Co.'s steel works at Newcastle, Australia.

Mr. Satoru Nishioeda, Chief Engineer of the municipal water-works of Tokio, Japan, is visiting in this country for the purpose of inspecting and studying water-filtration plants. Last week he was in Philadelphia.

Mr. Fred W. Johnson has been appointed Engineer of the Springfield (Mo.) Special Road District. All the work in the district is to be done by county labor under the supervision of the three Commissioners of the district.

Mr. Alex. E. Kastl, M. Am. Soc. C. E., Consulting Engineer, formerly Special Deputy State Engineer, New York State Barge Canal, Albany, N. Y., has moved to Nolan, Mora County, N. M., in connection with the development of land in that vicinity.

Mr. W. F. Monfort has resigned as Chemist of the supply and purification division of the St. Louis, Mo., water-works, in order to devote his whole time to private practice as Consulting Chemist and Bacteriologist, with offices at 706 North Van Zenter Ave., St. Louis.

Mr. C. E. Knickerbocker, M. Am. Soc. C. E., former Chief Engineer of the New York, Ontario & Western Ry. and re-

[illegible] Chief Engineer of the MacDonald Construction Co., New York City, has been appointed Cost Engineer, Division of Valuation, Interstate Commerce Commission, Washington, D. C.

Mr. David Van Alstyne has been appointed Assistant to the Vice-President of Operation of the New York, New Haven & Hartford R.R., with headquarters in New York City. Mr. Van Alstyne will be in charge of the test and store departments and of the handling of scrap, and he will have supervisory authority over the mechanical department in regard to organization, shop practice, approval of design, standards and requisitions.

Mr. Robert E. Kremers, Consulting Engineer, of Portland, Ore., has been appointed Chief of Highways and Bridges of the city of Portland, Ore., under Mr. Philip H. Dater, Assoc. M. Am. Soc. C. E., City Engineer. Mr. Kremers is a graduate of the civil engineering department of the University of Michigan, class of 1900, and for several years was Engineer of Bridges and Buildings of the Oregon Short Line R.R. at Salt Lake City, Utah.

Mr. J. H. Sanford, formerly Purchasing Agent of the New York, New Haven & Hartford R.R., has been appointed Purchasing Agent of the Connecticut Co., the Housatonic Power Co., the Berkshire Street Railway Co., the New York & Stamford Street Railroad Co. and the Westport Water Co. Mr. H. A. Fabian, Director of Purchases of the New York, New Haven & Hartford R.R. will have sole charge of that company's purchases. The appointment of an independent purchasing agent for the trolley companies is officially stated to be the last step in giving those companies a complete organization of their own, entirely independent of the management of the New York, New Haven & Hartford R.R. Mr. Sanford will make his headquarters in New Haven, Conn.

OBITUARY

J. A. McCague, Assistant Engineer, of Joseph T. Ryerson & Son, Chicago, Ill., was drowned while bathing on Aug. 16.

Prof. Charles Laden Adams, of the department of drawing of the Massachusetts Institute of Technology, died Sept. 17, at Antwerp, Belgium.

Henry Bratnober, a mining engineer, who prospected in many countries for the Rothschilds and Guggenheims, died Sept. 14, at his home in California.

Samuel McMurtie, a railway civil engineer of Denver, Colo., died Sept. 16, aged 57 years. He was born in Summit Hill, Penn., and was educated at Lehigh University. He was at various times a member of the engineering staff of the Denver & Rio Grande R.R., the Colorado Midland Ry. and the Southern Pacific Ry.

Edward Julius Hall, Assoc. Am. Inst. E. E., Vice-President of the American Telephone & Telegraph Co., died at Watkins, N. Y., Sept. 18. He was born at Perth Amboy, N. J., in October, 1853. Later his parents moved to Buffalo, N. Y., where he was educated in the public schools and at Sheffield Scientific School, Yale University, where he was graduated in 1873. He was identified with the telephone industry almost from the beginning and was the organizer of the local operating company in Buffalo, holding the offices of Vice-President and Manager. When the Buffalo company was taken over by the American Telephone & Telegraph Co. Mr. Hall became Manager of Traffic of the whole organization and devoted a large portion of his energies to the development of the long distance telephone business.

ENGINEERING SOCIETIES

COMING MEETINGS

INTERNATIONAL IRRIGATION CONGRESS.
[illegible]

AMERICAN ELECTRIC RAILWAY ASSOCIATION.
[illegible] New York City.

NATIONAL COUNCIL FOR INDUSTRIAL SAFETY.
[illegible] Continental Bank Building, Chicago.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.
[illegible] Convention at Los Angeles, Calif. [illegible] Chicago, Ill.

INTERNATIONAL ASSOCIATION OF FIRE ENGINEERS.
[illegible] Annual convention at New Orleans. [illegible]

AMERICAN GAS INSTITUTE.
Oct. 20-23. Annual meeting in New York. Secy., George G. Ramsdell, 29 W. 39th St., New York City.

AMERICAN ROAD CONGRESS.
Nov. 9-14. Atlanta, Ga. Permanent headquarters, American Highway Association, Colorado Building, Washington, D. C.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.
Oct. 6-9. Annual meeting at Boston, Mass. Secy., Charles Carroll Brown, Indianapolis, Ind.

NATIONAL MUNICIPAL LEAGUE.
Nov. 17-21. Annual meeting at Baltimore, Md. Secy., Clinton Rogers Woodruff, North American Building, Philadelphia, Penn.

AMERICAN PUBLIC HEALTH ASSOCIATION.
Nov. 30-Dec. 5. Annual meeting at Jacksonville, Fla. Secy., Prof. Selskar M. Gunn, Massachusetts Institute of Technology, Boston, Mass.

Northwestern Road Congress—The states participating in the 1914 Congress to be held in Milwaukee, Wis., Oct. 28-31, are Wisconsin, Illinois, Michigan, Iowa, Minnesota, North Dakota and South Dakota. A brief review of the status of the highway problem in each state represented will be presented by the highway commissioner of that state. Among the subjects for discussion are the following: "What Responsibilities Should be Placed on the County Engineer or Commissioner?" "What Should be the Salary and Tenure of Office of the County Engineer?" "When Should Highway Work be Let by Contract and When be Done by Day Labor?" "What is the Best System of Inspection for Contract Road and Pavement Construction?" One of the sessions will be devoted to the characteristics of types of roads, and here brick, concrete, bituminous, gravel and macadam roads will be discussed. At another session, the relation of good roads to the health and prosperity of a community will be considered. Further information may be obtained at 71 Sentinel Bldg., Milwaukee, Wis.

American Society of Municipal Improvements—The 21st annual convention of the Society will be held at the Hotel Somerset, Boston, Mass., Oct. 6-9. On the opening day, the Committee on Standard Specifications will meet with the various subcommittees, wood-block, brick, bituminous, asphalt, concrete, stone-block, broken-stone and gravel roads, and sewers. Among the papers to be read are the following:

"The High-Temperature Incinerating Plant at Savannah, Ga.," E. R. Conant, Chief Engineer, Savannah, Ga.; "Sewage Disposal, Preliminary Investigations Required," E. A. Fisher, Rochester, N. Y.; "Converting an Old Septic Tank into a Modern Two-Story Tank," Alexander Potter, New York City; "Economics of Sewage Filters," George W. Fuller, New York City; "Experimental Sewage-Disposal Plant of Brooklyn," George T. Hammond, Engineer-in-Charge; "Permanent Sediment Records of Water and Sewage," George C. Whipple, New York City; "Limitations of Water Filters," George W. Fuller; "Street Paving and Repairs," J. H. Sullivan, Boston, Mass.; "Sidewalks and Curbs," Harry S. Harris, Trenton, N. J.; "Sewer Construction and Maintenance," E. S. Rankin, Newark, N. J.; "Bleeding and Swelling and Longleaf Pine Paving Blocks," C. H. Teesdale, Madison, Wis.; "The Effect of Leaking Illuminating Gas on Bituminous Pavements," George C. Warren, Boston, Mass.; "Concrete Highways," George W. Meyers, Columbus, Ohio; "Napped, Recut and Grouted Granite-Block Pavements," William A. Howell, Newark, N. J.

The Secretary is Charles Carroll Brown, 702 Wilson Bldg., Indianapolis, Ind.

Western Society of Engineers—The first meeting of the season was held at the Society's rooms in Chicago, Sept. 14, with President E. H. Lee (C. & W. I. R.R.) in the chair. A paper on "Permeability Tests on Gravel Concrete" was presented by Morton O. Withey (University of Wisconsin). The use of rich mixtures and fine cement gave best results, and a very wet consistency increases the rate of leaking in a lean mixture. The proportioning and grading are important and a 1 : 1½ : 3 mix is very impervious. By grading the sand and gravel in accordance with Fuller's curve, it was possible to obtain watertight concrete of 1 : 9 proportions under pressures up to 40 lb. The tests related to gravel concrete, and did not cover the use of waterproofing compounds. In the discussion, F. H. Wilson (American Bureau of Inspection) mentioned tests of waterproofing floor slabs in which the best results were obtained without such compounds.

A paper on "Reactions in a Three-Leg Stiff Frame with Hinged Column Bases" was presented by N. H. Stineman (C. M. & St. P. Ry.). It included special formulas, the special application of which is in the design of reinforced-concrete frames of the type [illegible] such as bridge abutments which are now being built by some railways. The paper was of a mathematical character.

Engineering News

VOLUME 72 OCTOBER 1, 1914 NUMBER 14

An Ice-Breaking Train Ferry for Quebec

In the accompanying figures are shown the steamer "Leonard" just completed at Birkenhead, England, for the special service of transporting standard passenger railway trains or freight cars across the St. Lawrence River between Quebec and Levis at all seasons of the year. The weight of train to be carried is 1285 tons. The ferry has been designed so that the time taken in running the train upon the ferry, traversing the river (a distance of 2½ miles), and landing and coupling up the train will not occupy more than three-quarters of an hour. The particular features of interest in the design are: (1) the car deck which is raised or lowered through 18 ft., according to the stage of the tide; (2) the attachment of landing bridges to the ferry instead of to the shore houses; (3) the joints between bridges and car deck. The vessel is of the twin-screw type with a third ice-breaking propeller at the forward end. The principal dimensions are as follows:

Length overall	326 ft.
Breadth molded	65 ft.
Breadth over fenders	66 ft. 9½ in.
Depth molded	23 ft.
Mean draft	15 ft.
Speed (statute miles per hour)	15
I.hp., main engines	3200
I.hp., engines for ice propeller	420

The tidal deck is arranged above the main deck of the vessel and has 10 transverse girders, each end of which rests on a large nut which works up and down on a vertical screw, giving the deck the necessary range of action to suit the various conditions of tide. Three 272-ft. lengths of track are fitted on the tidal deck, each supported on lattice girders. The deck-lifting screws are hung from ball bearings supported on strong columns. These columns are stayed by lattice buttresses against fore-and-aft and transverse thrusts, while below the main deck a strongbraced strut is built, in way of each column, to distribute the load to the keel of the ship. The main deck and hull are strengthened by additional intercostals, etc., to insure sufficient strength to resist the stresses induced by the heavy loads on the tidal deck. The braced columns below the main deck also serve to carry the worm gearing for the deck-lifting screws.

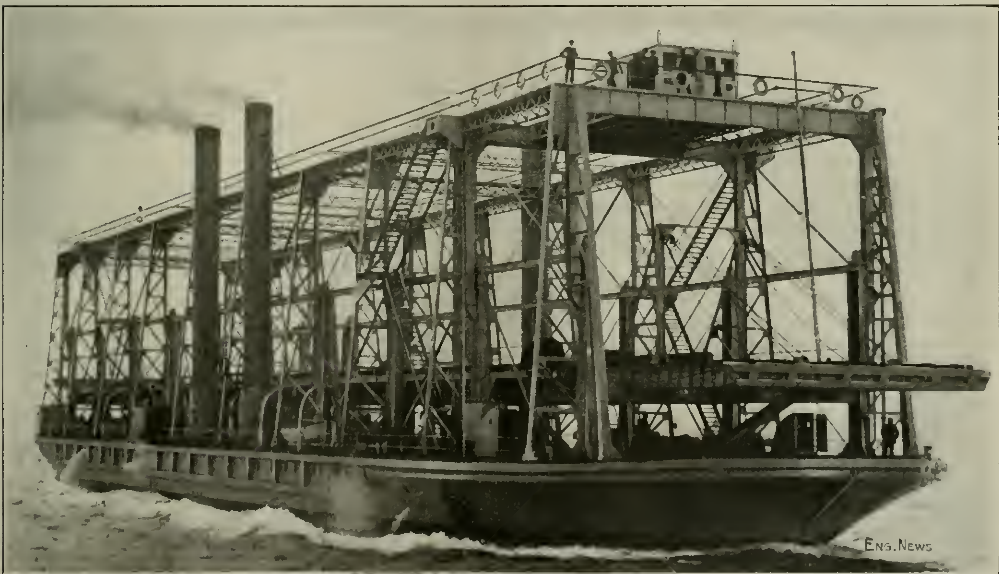

Fig. 1. Quebec Car Ferry "Leonard"

At each end of the tidal deck, an adjustable hinged gangway is suspended by means of treble purchases from struts fixed on the deck. These gangways are arranged, with ball-and-socket joints at the ends of each of the girders carrying the rails, to allow for any heel of ship or change of trim which takes place while loading or unloading the ferry. A special motor controls each gangway.

Above the highest position of coaches on the tidal deck,

Fig. 2. Longitudinal Elevation of Quebec Car Ferry "Leonard"

A promenade is arranged all round the vessel with a bridge platform, at the forward end, carrying a pilot house and chart room. The promenade and bridge are carried on lattice girders supported by the buttresses. Special arrangements are made to prevent any stress which would result from the bending moment on the hull being taken by the girders supporting the promenade.

The boiler rooms are arranged in wing compartments alongside with coal bunkers and tidal deck engine room between them. The main propelling engines are situated abaft the boiler rooms and the engines for the ice propeller are placed in the hold just abaft the fore-peak bulkhead. A special feed-water tank is built in the double bottom extending from bilge to bilge for a length of [illegible] frame spaces.

Accommodation is arranged for officers and crew on a flat below the main deck forward on both sides of the ship. Everything necessary for full day and night crews is provided.

The propelling machinery comprises two sets of triple-expansion engines. The shafts and propellers are made strong enough to withstand any stresses imposed by striking solid ice. The propellers are of nickel steel. The forward (ice) propelling engine is [illegible]. This pro-

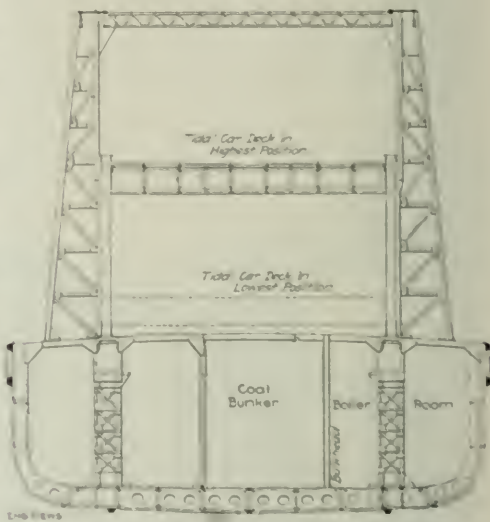

Fig. 5. Midship Section of Ferry "Leonard"

Fig. 4. Lift Screw and Nut [illegible] Train Deck Girder

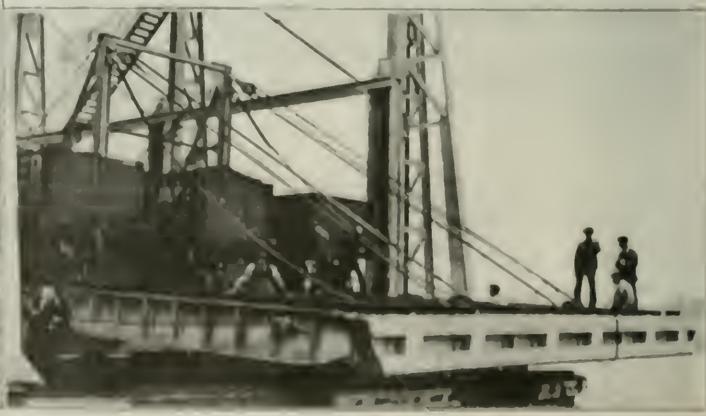

Fig. 3. Track Gangway of Train Deck; Car Ferry "Leonard"

peller runs idle in summer. The deck-lifting engine is a heavy high-pressure type driving a shaft athwartship through double helical spur gears. At each end of this second shaft, miter gears engage a fore-and-aft shaft on either side of the ship. These long shafts in turn work the deck-lifting screws by worm-gear connections. There is interposed between wheel and screw, however, a loose forged sleeve with sliding key. The lifting nuts in which the screws work are of heavy gunmetal, fitted into the train-deck structure.

The steamer is electric lighted. There is an electric winch with two winding drums fitted between girders of the tidal deck for hauling the carriages on or off the ship. Two powerful steam windlasses, one on each side of the ship, are fitted with slip drums for mooring.

This ferry was built to the order of the Commissioners of the Transcontinental Ry. of Canada, by Cammell Laird & Co., of Birkenhead. These details are presented by courtesy of the American agents, John Reid & Co., New York City.

The New York Rapid Transit Railway Extensions

By F. Lavis*

SYNOPSIS—The greatest engineering work in the world, measured by the amount of expenditure involved, is the extension of the rapid transit railway system of New York City. More engineers are now working on this great enterprise than on any other single work anywhere. The work is of interest not only in connection with the development of a vast transportation system; but because the tasks of construction involved are instructive to engineers engaged in a great variety of work. In order to present adequately the important features of this work for the benefit of the engineering profession, we have arranged with Fred Lavis, one of the highest authorities on tunnel construction in this country, to make a careful study of the entire work. Mr. Lavis has given much time to this task and has had the hearty coöperation of the members of the engineering staff of the Public Service Commission, whose courtesies and aid are freely acknowledged. The first of Mr. Lavis's articles is printed below and will be followed in succeeding issues with additional articles, each dealing with some special feature of this great work.

I—History and Extent

Extensions to the existing systems of rapid transit in the City of New York have been planned which will involve an estimated expenditure of \$366,000,000. The construction of these lines is now well under way and is being rapidly pushed forward at a rate which, it is hoped, will insure their completion by the end of the year 1917. The length of new line is altogether 110 miles, comprising 325 miles of single main-line track. These additions will make the total length of the completed system of rapid-transit railways in the city 230 miles, with 621 miles of single main-line track. The mileage of main-line track will thus be approximately doubled, though it is expected that the capacity for handling passengers will be increased threefold or fourfold.

The magnitude of this work may be at least partly realized by comparison of its cost with that of the Panama Canal, which, including the \$50,000,000 paid to the French, is to cost about \$375,000,000. This vast enterprise in the City of New York is progressing literally under the feet of its five million inhabitants and the other several millions of the adjacent territory whose business brings them frequently to the city, with hardly any notice or disturbance of the regular routine of business.

The cost is to be borne in approximately the following proportions partly by the city and partly by the two operating companies which will divide the territory between them.

City of New York	\$200,000,000
Interborough Rapid Transit Co.	105,000,000
New York Municipal Railway Corporation	61,000,000

The first of these two operating companies, The Interborough Rapid Transit Co., generally spoken of as "The Interborough," operates the present subway which traverses the length of Manhattan Island, reaching into the Borough of Bronx at one end and a short distance into Brooklyn at the other. It also operates the four lines of elevated railway in Manhattan and the Bronx, as well as the surface lines in those boroughs. The so called Steinway or Belmont Tunnel, running from 42nd St., New York, under the East River to Long Island City, was built about five years ago by interests closely associated with the Interborough but has never yet been utilized. It is now, however, to be finished, equipped and operated by that company, in conjunction with the other lines of its system.

The New York Municipal Railway Corporation is a company formed by the Brooklyn Rapid Transit Co. to finance and operate that part of this new system of railways which falls to its share. The Brooklyn Rapid Transit Co. is familiarly known as the "B. R. T." and both it and the New York Municipal Railway Corporation will be generally so referred to hereafter. It controls all the elevated and surface lines in Brooklyn including those which reach the famous ocean summer resort at Coney Island.

Heretofore, the operations of these two systems, the Interborough and B. R. T., have been almost exclusively confined to territories divided by the East River, the former to Manhattan and the Bronx on its west side, and the latter to Brooklyn and the Borough of Queens on the other side.

By the new arrangement, the B. R. T. gains an entrance into Manhattan by a new tunnel from the business center of Brooklyn to the lower end of New York, thence via Broadway and 7th Ave. through the center of the business and amusement districts to 59th St. Thence it turns eastward and crosses the East River on the Queensborough

*Consulting Engineer, 50 Church St., New York City.

Bridge to a connection with the proposed lines to Astoria and Flushing. It then reaches lower New York by a series of underground loops connecting the three lower East River bridges and the new tunnel just referred to, which will permit also continuous circulation of its trains instead of bringing them in as at present to stub-end terminals at the New York ends of the bridges.

The Interborough, besides a new north and south line in Manhattan, will reach the Borough of Queens and will have two lines to Astoria and Flushing from 42nd St., via the Steinway Tunnel. Its present line to Brooklyn is to be extended by two branches, each to a point some five or six miles beyond its present terminus at Atlantic Ave. into the residential section of that borough.

The Borough of Queens, comprising Long Island City, Astoria, Jamaica, Flushing, etc., which up to the present, has never been served by any so called Rapid Transit Lines, will now have the two elevated lines referred to which are to be operated jointly by the two companies, linked up to both the Queensborough Bridge, the Steinway Tunnel and the 2nd Ave. elevated, and thus connecting directly with all lines in Manhattan and other boroughs.

It is of some interest perhaps to note that many of the routes in Queens through Roosevelt Ave. is through

Fig. 1. Route of an Elevated Railway through a Cabbage Field in Queens Borough

a street not yet constructed and marked on the ground only by monuments, being now actually used for market garden purposes, as may be seen by the accompanying photographs, Figs. 1 and 2, which were taken looking along the center line of the street.

The Borough of Richmond (Staten Island) is eventually to be connected with the B. R. T. system by a tunnel under the "Narrows," the tidal channel connecting the outer bay with New York Harbor. This, however, does not form part of the present (proposed) scheme of construction.

As part of its system of records the Commission has had taken hundreds of photographs showing clearly the character of the streets and of each building adjacent to or near the proposed route, which might be expected to be affected in any way by the construction. This series of photographs is not only of great value for reference in case of litigation or claims for damages which might be due to the work in hand, but forms a unique and interesting historical record of the appearance of the city at this time.

Earlier History

The adoption of the present scheme and the consummation of the contracts under which the work is now going forward are the result of negotiations which have been carried on continuously almost ever since the completion of the present subway in 1904.

Almost as soon as operation of that line was started it was seen that the profits from operation were going to be much greater than had been expected. The public lost sight of the fact that when the contracts had been first proposed it was with considerable difficulty that anyone had been induced to accept them, and there was a great outcry, especially by the sensational newspapers, against the so called monopoly of the Interborough, and the alleged one-sided bargain with the city, and the demand arose that any future subways be operated as well as owned by the city.

Various forms of contract were therefore proposed, but none of them which required the use of private capital for construction was acceptable to bidders (see Eng. News, Mar. 10, 1910, p. 288 for a discussion of the so called Triborough route). Finally it was determined to start to build certain sections with the City's money, and contracts were let for the construction of part of the Fourth Ave. subway in Brooklyn, and the Centre St. loop in Manhattan, but no arrangement was made for their operation, nor was any made until the final agreement arrived at between the Public Service Commission, the City and the two operating Companies on Mar. 19, 1913.

The Public Service Commission, which succeeded the old Rapid Transit Commission, was appointed and took office in July, 1907. A new city administration under Mayor Gaynor, and including among its members Messrs. Mitchel (now Mayor), Prendergast and McAneny, came into office Jan. 1, 1910.

The bids for the Triborough were called for in October of that year. As noted there were no bids for construction by private capital, but numerous bids were received for construction alone with city funds. The awards for the latter were, however, held up for various reasons in spite of strenuous protests from that section of the press and public which allowed the large profits of the Interborough and the alleged monopoly of this latter to obscure their judgment as to the best interests of the city and the traveling public, which many competent authorities considered were not best served by the proposed scheme for the Triborough route.

Fig. 2. A Street in Queens Borough on Which an Elevated Railway Will Run

The objections to the Triborough were principally because it was proposed to build the lines without any arrangement for their operation, because it was felt that the new lines should be linked up to, and form a part of the present system (the Triborough as laid out would not have permitted transfer except on payment of an extra fare), because the route was not considered well laid out, and because it was inadequate to meet the growing needs of the city and to properly provide for all the boroughs, and, above all, because at the time the amount of city money available for railway construction

was very limited (not more than 60 to 70 million dollars).

From the beginning, Mayor Gaynor's administration, through the Board of Estimate (the approval of which is required on all expenditures of the city's money) adopted an attitude of coöperation with the Public Service Commission, and the present contracts are the result of nearly three years of very hard work and the most persistent, patient and diplomatic negotiation between these bodies and the companies which have now finally undertaken the operation. It was necessary that the city's credit be strengthened and its borrowing capacity be enlarged, and this in itself was no small part of the task.

During all this period, certain sections of the public press were very bitter in urging their own views, and there were many committees of citizens, public meetings, etc. At one time the Interborough entirely withdrew and everything was to be given to the B. R. T. The delay was well nigh intolerable owing to the congested and crowded condition of the present lines of transport; but it is felt now that the delay has been more than justified by the comprehensiveness of the scheme evolved, the consolidation of the lines into two large systems, either of which can be traversed throughout its length for a single fare, and the conclusion of equitable contracts by which not only will the city own the lines free of cost at the end of 49 years, but will have shared in such profits as there may be beyond a certain stated amount.

It may not be out of place to emphasize the advantage to the city from the perpetuation of the virtual monopoly of these two companies under fair and efficient regulation. The public is not only allowed a ride for a single five-cent fare over the lines of a complete system reaching almost to every part of the City of Greater New York, but the city shares in such profits as there may be from the consolidation of the management and its own contribution of credit in obtaining the greater part of the money at low rates of interest. A most important consideration is also that which provides complete arrangements for the operation of all routes in advance of design and construction, so that these latter can proceed with an intelligent conception of the operating requirements.

Character of the Lines

The 325 miles of new lines already decided on will be built underground in the more thickly populated sections of Manhattan and Brooklyn and elevated in the outlying districts. The subway will embrace various types of structures, both for two, three and four tracks, the latter in some cases all at the same level; in others as a double-deck structure, each level having two tracks. There are to be subaqueous tunnels under the rivers, some sunk from the surface by methods similar to those developed at the Detroit tunnel, and others probably to be driven by the shield method. The elevated will be mostly a steel structure of the familiar type, though of modern construction, but in some cases where parkways or boulevards are crossed or traversed it is being built of reinforced concrete with special attention to artistic architectural design, as illustrated in Fig. 3.

Fig. 3. Design for Ornamental Reinforced-Concrete Viaduct on Queens Boulevard

Improvements in Design

On all the new lines a special effort will be made to locate all the stations on tangents so as to avoid the inconvenience and possibility of danger from the space between the car and the platform on curves, which occurs at some places on the existing subway lines. An endeavor has also been made in so designing the structure at the junctions and connections of main lines and branches, etc., to avoid grade crossings of the various tracks. With the abnormal density of traffic during the rush hours this is very desirable, as the slightest delay at any one point may be, and generally is, reflected over the whole system. Footpaths at the sides of the tunnels at the level of the car platforms, similar to those built in the Pennsylvania R.R.'s New York tunnels, are to be constructed so as to provide a walk for passengers in case a train should meet with an accident and be stalled.

The new subway will be divided by partitions so as to separate the trains going in different directions, with the expectation of thereby so improving the ventilation by utilizing the piston-like action of the trains to change the air, that the accumulation of excessive heat so noticeable in the summer in the present subway may be avoided.

In furtherance of this also, waterproofing will be omitted when it is possible to do so, as it is thought that the practical inclosure of the existing subway in a waterproof envelope materially helps to prevent the diffusion of the generated heat through the walls of the structure. As is well known, locally at least, this accumulation of heat in the subway in the summer time, due to the heating of the motors, the friction of brakeshoes on wheels, the wheels on the tracks, etc., has made traveling very uncomfortable at times, the installation of expensive ventilating apparatus having only partially alleviated the trouble. In the present subway there are no division walls between the tracks, and while the trains stir up the air in passing, they do not change it very much, and not nearly to the extent so noticeable in all the single-track tube tunnels already built under the waters of New York Harbor and on all the lines of the Hudson & Manhattan Co.

Another point of interest is the provision of or for three tracks on the lines in the outlying districts where the density of travel does not require four tracks for

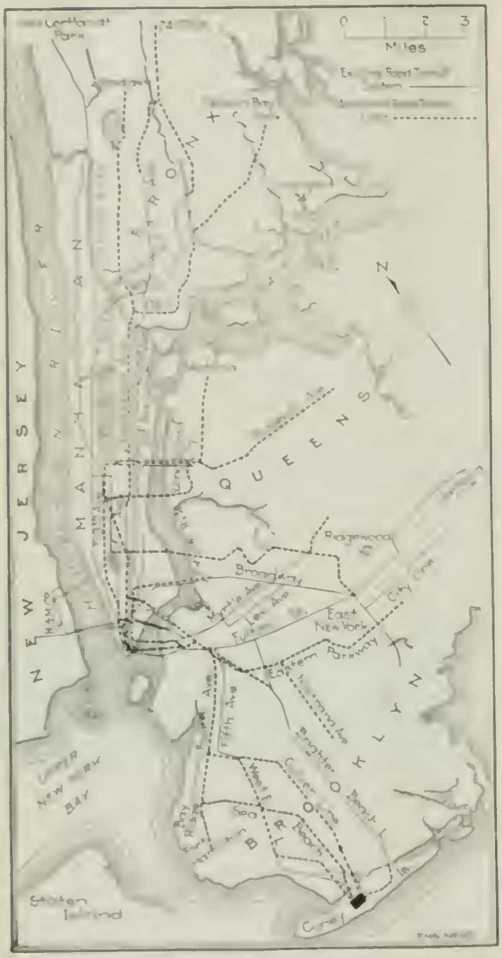

FIG. 4. THE OLDER NEW YORK RAPID TRANSIT SYSTEM AND THE NEW LINES NOW UNDER CONSTRUCTION AND PLANNED

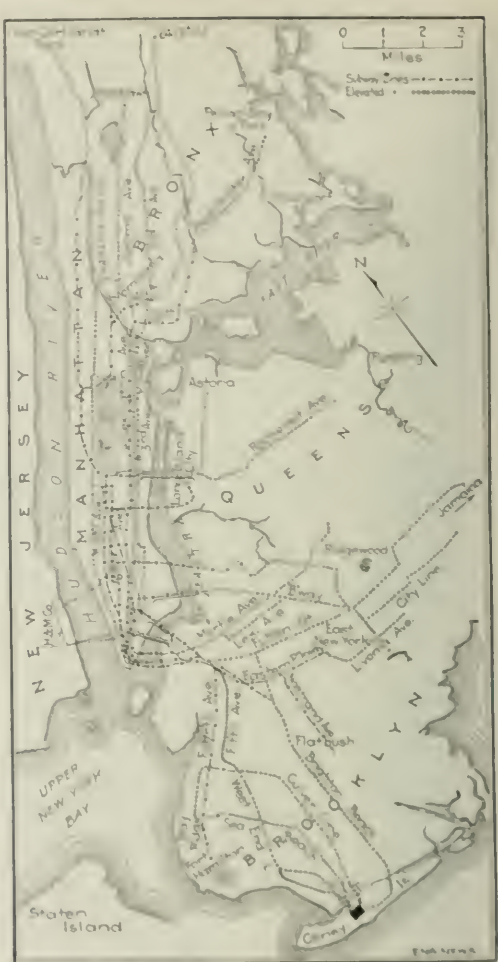

FIG. 5. SUBWAY LINES AND ELEVATED LINES IN THE COMPLETED RAPID TRANSIT SYSTEM

continuous express service. This allows express service one way during the rush hours.

EXISTING LINES

The principal features of the rapid transit lines now in operation in Manhattan are the four elevated lines running north and south through Second, Third, Sixth and Ninth Aves., the principal parts of which were built between 1870 and 1880, and the original subway, built between 1900 and 1904.* In Brooklyn the principal elevated lines, which were built soon after those in Manhattan, radiate from the old Brooklyn Bridge, one group eastward toward Jamaica and the other toward Coney Island. Some of these last-mentioned lines, after reaching a point some five or six miles from the bridge, drop to the surface and remain there for the rest of the way to Coney Island, and all these are to be elevated (or depressed in open cuttings), and are shown on the map as now elevated lines of the B. R. T., although through trains from the bridge to Coney Island are operated over them now.

TRAFFIC

Almost ever since the Brooklyn Bridge was first put into operation it has been recognized that the congestion and crowding of the transportation lines of New York has been unequaled in any other transportation system in the world. The opening of the present subway in 1904, although it had then a capacity of 400,000 passengers per day, afforded little relief. By the lengthening of the express platforms to accommodate 10 instead of eight cars, the installation of the most modern and improved types of automatic block signals, brakes, car

*[illegible]

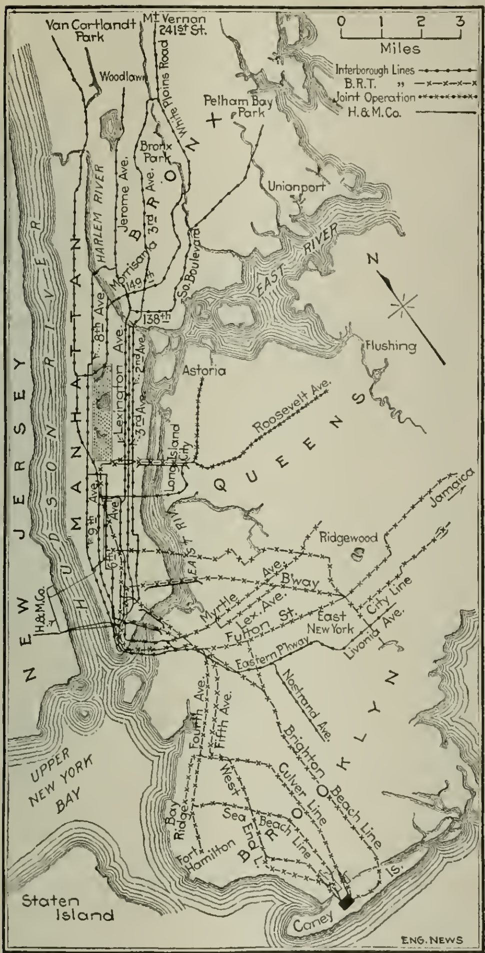

Fig. 6. The Systems of the Two Operating Companies, the Interborough and the Brooklyn Rapid Transit

and air-line couplings, center side doors, etc., its capacity was increased so that 1,250,000 passengers can be and have been handled in 24 hours, but the crowding during the rush hours is as bad as ever on all lines.

The following figures, condensed from a table given in the last report of the Public Service Commission, with the addition of the figures for 1913, show the great and greatly increasing amount of travel, and justify the attempt to meet the requirements by the system now proposed, enormous though its cost will be:

NUMBER OF FARES COLLECTED (MILLIONS)

	Subway	Manhattan and Bronx Elev.	Manhattan and Bronx Surface	Brooklyn All lines	Queens Surface	Total
1898......	...	184	321	221	9	735
1903......	...	246	427	304	16	993
1908......	200	202	411	419	30	1342
1913......	327	307	494	484	47	1659

(Note—In 1905, its first year of operation, the Subway carried 75,000,000 passengers. In 1914 it carried 340,400,000 passengers.)

Ever since the opening of the present subway in 1904, plans for extensions have been under consideration, first by the old Rapid Transit Commission and since then by its successor, the Public Service Commission for the First District of New York, but for the reasons already given there were various delays until the present comprehensive scheme of routes was developed to give so far as possible and, as may be seen by the maps, fair and equitable service to all parts of the greater city. There had been for some time a feeling that Manhattan had been unduly favored at the expense of the other boroughs, and while this to some extent is reasonable, both that it had, and that it should be, there can be little fault found with the scheme now laid out.

The routes of the various extensions and their character are shown on the maps, Figs. 4, 5 and 6, but for the benefit of those not entirely familiar with the situation it may be well to briefly enumerate their salient features and some of the details of the scheme.

New Lines

The Interborough—In Manhattan the Second, Third and Ninth elevated lines will complete the installation of third tracks from the down-town business section to above 125th St., thus enabling express trains to be run down-town in the morning and up-town at night.

The present subway will be divided at 42d St., the lower part being connected with the new Lexington Ave. subway, giving a four-track line all the way up the East Side, splitting into two three-track branches in the Bronx after it crosses under the Harlem River; the upper part will be connected to the new Seventh Ave.-Varick St. line, thus giving a through route up and down the West Side, and placing the Pennsylvania Terminal at 33d St. on a main line of the Rapid Transit system. The present West Farms branch of this line in the Bronx will be extended some five miles farther to the Mount Vernon line at the northerly boundary of the city.

The Brooklyn end of the present subway will be extended from Atlantic Ave. by two branches via Flatbush Ave. and Eastern Parkway into the residential sections of Brooklyn.

The part of the present subway on 42d St. between the Grand Central Station and Times Square will be operated by a shuttle service between the main lines on the East and West Sides.

The Steinway tunnel will be extended back to Times Square and forward to the east end of the Queensborough Bridge, where it will connect with the two lines to Astoria and Flushing, over which both systems are to have trackage rights. The Second Ave. elevated will be connected to the Queensborough Bridge and so to these same two lines.

There will be certain other small extensions and connections to allow the proper linking up of the various lines and permit desirable or convenient combinations in the operation of trains, all of which are shown on the maps.

The Interborough will thus have, besides its four elevated lines, four double- or three-track branches in the Bronx leading to two main trunk lines (four-track) throughout the length of Manhattan on Fourth and Seventh Aves. to two tunnel routes under the East River, joining under Fulton St., the main business street of Brooklyn, and then spreading out again into two branches into the residential section of that borough. The distance from the upper end of the Bronx to the

ends of the lines in Brooklyn is about 26 miles. From the center of this system there will be the offshoot at 42nd St. via the Steinway tunnels to the lines in the Borough of Queens to Astoria and Flushing.

THE BROOKLYN RAPID TRANSIT.—Besides certain extensions of various lines in Brooklyn and the construction of the elevated structures in South Brooklyn on the Coney Island lines, as already referred to, the main features of the contract of this company with the city are those which provide for its entrance into New York and the linking up of the four bridges across the East River into lines of through travel instead of establishing terminals at their ends. There is one important new line in Brooklyn, the Fourth Ave. subway, which was started some five years ago, a considerable part of which is now nearly completed; this route extends from the Manhattan Bridge through Fourth Ave. to Fort Hamilton, and will be part of an important new route to Coney Island.

The principal line of the B. R. T. in New York will be that already described, running from the center of Brooklyn under the East River and via Broadway and Seventh Ave. to 59th St., the Queensborough Bridge and to Astoria and Flushing. This will be a four-track line in Manhattan above City Hall (Park Place).

From a certain point of view, the linking up of the New York end of the three down-town East River bridges, the old Brooklyn Bridge, the Manhattan just above it, and the Williamsburg Bridge, a mile farther up the river, is one of the most interesting features of the whole scheme. For years the crowding and congestion at the ends of the Brooklyn Bridge were worse than even on the elevated and subway lines. Nearly all the travel from the lines of the B. R. T. was concentrated at this one bridge and brought over to a stub-end terminal at the New York end. In an attempt to provide better means of communication between Brooklyn and New York, the Williamsburg Bridge was built and opened in 1903 and the Manhattan Bridge in 1909. No provision was made, however, for the operation of these bridges or their proper connection with any of the existing lines of communication, and the people from Brooklyn have been brought over to the New York ends and dumped there, to make the best of their way to their destination. The travel between Brooklyn and New York is mostly all toward New York in the mornings and toward Brooklyn at night, all four of the East River bridges providing for lines of rapid transit (two to four tracks) as well as for street cars, ordinary vehicular traffic and pedestrians.

To eliminate the stub-end terminals the so called Centre St. loop was planned to connect up the New York Ends of these three bridges, and its construction was started in 1907, though no arrangement was made for its use. Now, however, it is to be completed and further extended down along the New York side to a connection with the new tunnel which is to connect the B. R. T. with its Broadway line. This will enable all the trains to circulate, coming over on one bridge, continuing and returning via another instead of coming into a terminal in the congested district and having to back out.

There will be also another new route established under 14th St., New York, and the East River to the easterly section of Brooklyn (East New York).

FARES

The contracts between the city and the two operating companies provide for a single fare of five cents on each system, with free transfers at intersecting points for a continuous ride in the same general direction. On the Brooklyn system, transfers will be exchanged between the elevated lines and the subway lines, but on the Interborough only such transfers as are now given will be provided between the elevated railroads and the subway. On the existing lines, as they stand today, the longest ride obtainable for five cents is through the subway from Atlantic Ave., Brooklyn, to Van Cortlandt Park or 242nd St. on the Broadway branch, a distance of $17\frac{1}{2}$ miles. Under the dual system, as the new system has been commonly called, it will be possible to travel over the Interborough subway from the terminus of the White Plains Road line, near the northern city boundary, the whole length of the Bronx and Manhattan, under the East River to Brooklyn, and through the Eastern Parkway subway and its extensions to New Lots Ave.—a distance of about 26 miles—for one fare and without change of cars.

The longest ride on the Brooklyn system will be from Flushing, at the end of the Corona branch, to and across the Queensborough Bridge, through the Broadway subway in Manhattan, under the East River to Brooklyn and through the Fourth Ave. subway and its connections to Coney Island, about 21 miles, for five cents.

The fare from the center of Brooklyn to Coney Island had always been 10 cents (15 cents from New York) up to within the last few years, when a general agitation for its reduction was started.

As soon as the connections of the Fourth Ave. subway in Brooklyn with the elevated lines are made and through-train operation is possible from Manhattan to Coney Island, the five-cent fare between these points will apply. This, it is estimated, will take about 18 months.

CHANGES IN METHODS OF COMMUNICATION IN NEW YORK

Before leaving the general subject of routes, it may not be amiss to call attention to the radical change in the character of the means of communication between New York City proper (Manhattan) and the surrounding territory, which has taken place in the last six or eight years. Direct land communication has never been possible except to the north, while the most densely populated of the surrounding districts have been to the east in Brooklyn and the west in New Jersey, with which communication was only possible by means of boats of one kind or another, and from both of which districts enormous numbers of people come to Manhattan daily.

Brooklyn was connected with Manhattan by means of the famous Brooklyn Bridge as long ago as 1883, but with the completion of that structure progress along these lines stopped for almost a quarter of a century. Within the last eight years, however, three more bridges have spanned the East River and six pairs of railway tunnels have been put into service under the rivers; one pair more has been built, three pairs are to be built under the present scheme, making four bridges and ten pairs of tunnels for railways, besides which there have been built two tunnels for gas and one for water supply, and thus making practical the direct physical connection of Manhattan by land lines of communication with the populous districts to the east and west.

Collection and Disposal of City Refuse, Washington, D. C.

By J. W. Paxton*

SYNOPSIS—This is the fourth and last article describing the method of operation of the Washington Street Cleaning Department. Previous articles appeared in Engineering News *of July 9, Aug. 6 and Aug. 27, 1914. The present article describes the collection and handling of garbage and refuse, which is done by contract, from the point of view of the city inspectors and supervisors.*

The collection and disposal of city refuse for the District of Columbia is done by contract, under the supervision of the Street Cleaning Department. Five contracts are let; namely, for the collection and disposal of garbage, ashes, miscellaneous refuse, dead animals and night soil.

The main features of the contracts are as follows:

Garbage—(1) Collections and disposal of garbage are made daily, including Sundays, from such hotels, apartment houses, markets, and other like places within the City of Washington and such of its suburban sections as may be designated, from time to time, by the Commissioners of the District of Columbia.

(2) Collections and disposal of garbage are made daily, excluding Sundays, from May 16 to Oct. 15, both days inclusive, and three times a week from Oct. 16 to May 15, both days inclusive, from all places not embraced in the preceding paragraph within the existing fire limits of the District of Columbia and certain of the more thickly populated sections on the outside of and adjacent to the fire limits.

(3) Collections and disposal of garbage are made three times a week from May 16 to Oct. 15, both days inclusive, and semiweekly from Oct. 16 to May 15, both days inclusive, from all places not included in the preceding paragraphs, in the City of Washington and its suburbs, as such suburbs may, from time to time, be designated by the Commissioners of the District of Columbia.

(4) The collection of garbage is made in wagons carrying a covered iron box which is lifted from the wagons and loaded on cars at the transfer station. This box containing the garbage is then shipped by rail to the disposal plant owned by the contractor, located about 32 miles from Washington, and the garbage is there disposed of by the reduction process.

Ashes—(1) Collections and disposal of ashes within the existing fire limits of the District of Columbia and certain of the more thickly populated sections outside of and adjacent to the fire-limits, are made weekly, from Apr. 16 to Oct. 31, inclusive, and semiweekly from Nov. 1 to Apr. 15, inclusive, from private residences, boarding houses, lodging houses not exceeding 25 rooms, and apartment houses containing not more than four families, and other like places, as may be designated by the Commissioners of the District of Columbia.

(2) Collections and disposal of ashes are made from all private residences and such other like places corresponding to those included in the preceding paragraph from the remainder of the City of Washington and its suburban sections, as said suburban sections may from time to time be designated by the Commissioners of the District of Columbia, weekly, throughout the entire year.

(3) The collections are made in wagons with canvas covers and disposed of by filling low ground on the outskirts of the city.

Refuse—(1) Collections and disposal of miscellaneous refuse in the City of Washington and its more densely populated suburbs, as such suburbs may from time to time be designated by the Commissioners of the District of Columbia, are made once a week from all private residences, boarding houses, and lodging houses with not to exceed 25 rooms, and apartment houses containing not to exceed four families, and other like places, as may be designated by the Commissioners of the District of Columbia, and from such public waste boxes as may be established by the street-cleaning division in the machine-swept section of the City and District.

(2) The collections are made in wagons suitable for this purpose and what is not salable is disposed of at an incinerating plant owned by the contractor.

Dead Animals—(1) The collection and disposal of dead animals daily, including Sundays, throughout the year, from every part of the District of Columbia, is required upon notification to the contractor of the existence of said dead animals.

(2) The collections are made in vehicles suitable for the purpose, and the disposal is accomplished by the reduction process at a plant owned by the contractor located about 4 miles from the city.

Night Soil—(1) The collection and disposal of night soil from all privies, and from all streets, avenues, alleys, roads and open lots in the District of Columbia is required upon receipt of notice from the Superintendent of Street Cleaning.

(2) The collections are made in air-tight receptacles designed for that purpose and transported therein on barges about 8 miles from the city and there used as fertilizer on a farm.

Ashes from Public Buildings—(1) The collection and disposal of ashes and refuse from buildings under the control of the Commissioners of the District of Columbia is required as such may accumulate.

(2) This work is done by contract under the direction of this division but paid for from the appropriation for the maintenance of each building in proportion to the quantity removed.

Collection

Householders' Instructions—The householders are required to conform to the police regulations as to receptacles, separation of material and accessibility. Cards of instructions to householders containing extracts from the police regulations are distributed on request or to those who show evidence of the need of instruction.

The contractor is required to call on the same days each week, collections to be made at any time between

*Superintendent of Street Cleaning, Washington, D. C.

7 a.m. and 6 p.m.], and he is to make free use of horn or gong as a signal of his presence. Failure of the contractor to promptly and properly collect material lawfully offered costs him a fine of from $1 to $2 for each neglect.

The supervision of this work is in charge of one man, reporting directly to the Superintendent. He has under him a force of five inspectors and a complaint clerk.

INSPECTION—It is manifestly impossible, and it is not considered necessary, for this force to supervise the collection of every mass of material from every house. Inspection can be made in a general way, information obtained as to whether each wagon is on its regular route on the schedule day, special attention being given to

DISTRICT OF COLUMBIA
STREET CLEANING DIVISION

WASHINGTON, Oct. 15th 1913

Mr. M. R. Ready

CONTRACTOR for COLLECTION OF Misc. Refuse.

THE FOLLOWING COMPLAINTS HAVE BEEN RECEIVED AT THIS OFFICE. YOU ARE REQUESTED TO IMMEDIATELY REMOVE THE MATERIAL FROM THE PREMISES SPECIFIED AND TO RENDER A REGULAR COLLECTION SERVICE HEREAFTER, IN ACCORDANCE WITH THE TERMS OF YOUR CONTRACT.

COMPLAINT NUMBER	LOCATION
10,014	452 - 2nd [illegible]
10,015	304 - M
10,016	919 - Jefferson
10,017	702 - L NE
10,018	545 - Eye SE

Delivered to Contractor 10/17 [illegible]

Superintendent per [illegible]

FIG. 1. DAILY LIST OF COMPLAINTS AS SUPPLIED TO CONTRACTORS

those which are or likely to be [illegible], and all complaints are investigated.

The investigation, however, being after the cause of the complaint, it is sometimes difficult to ascertain whether the fault was the householder's, in not making the proper separation or the waste accessible, or the collector's.

COMPLAINTS—In spite of this fact, the work of holding the contractor to the specifications depends to a large extent on complaints received from householders, each acting on his own premises as an inspector. Unfortunately, complaints received cannot be accepted as an absolute criterion of conditions. The householders often do not conform to the regulations, and service is refused for that reason.

During the year ending June 30, 1912, 693 garbage, 1198 ash, and 2983 refuse complaints were investigated. Of the total garbage complaints, but 36 or 5¼% were found on investigation to be the fault of the contractor; [illegible] or 38.3% were found to be the result of violation on the part of the householder of the police regulations regarding the disposal of refuse, while in 390 cases, or 56.3%, the fault could not be definitely placed.

In the case of ashes but 115 complaints, or 9.6%, proved to be the fault of the contractor; 802 or 67% are chargeable to the failure on the part of the householder to observe the regulations, principally regarding accessibility, while 279 or 23.4% are classed as doubtful. In the refuse service, 730 complaints, or 24.5%, were found to be the fault of the contractor, 836 or 28%, the fault of the householder, while 1419, or 47.5%, were classed as doubtful.

ACTING ON COMPLAINTS—Upon receipt of either a garbage, ash or refuse complaint, the papers referring to the case are placed in an open-sided envelope, 4x9½ in., which is given a complaint number, and the blanks for location and date filled in. These envelopes are then turned over to the inspector in whose district the complaint originated. The information suggested on the face of the envelope (including a description of premises, how collections are made, date of last collection, etc.) is obtained and any additional observations written under remarks on the back, together with the inspector's conclusion as to the location of the fault. When fines are fixed, they are considered as liquidated damages and not as penalties. The envelopes are filed according to location of the complaint and cross-indexed by number and date.

COMPLAINT RECORD—A monthly record of such complaints is also kept on a Complaint Record, 35¾x8½ in., which gives a summary of requests and complaints received each day, the results of the investigations as to fault and fines imposed.

The form shown in Fig. 1 is a list supplied each day to the contractor of complaints received at the office, which also serves as an order to collect the material immediately and as a warning against such failure in the future. The actual size of the card is just twice the reproduction.

COLLECTIONS—The form shown in Fig. 2 is a notice issued by contractors, in accordance with specifications, to householders previous to any change in collection days. Fig. 3 is a summary of daily reports from contractors showing the working force and the amount collected. The actual size is 35¾x8¼ in.

GARBAGE WILL BE COLLECTED
From October 16 to May 15, between 7 A. M. and 6 P. M.
MONDAY, WEDNESDAY & FRIDAY

GARBAGE consists of the refuse of animal and vegetable matter which has been used or was intended to be used as food. Cans, glass, broken crockery, paper, ashes and other refuse are removed free by other than the garbage collectors, and if mixed with the garbage, it is a violation of the Police Regulations. Such mixture will be refused by the collectors.

RECEPTACLES. Garbage must be placed in water-tight metal receptacles, provided with a tight cover and a handle, with a capacity of not less than 3 nor more than 10 gallons. More than one receptacle containing less than 10 gallons is not allowed. Garbage must be kept dry.

ACCESSIBILITY. Receptacles must be placed by the householder at the rear entrance to the premises, or in case there is no rear entrance, in the areaway or other convenient place in front of the premises, and gates or doors must be left unfastened on collection day. The collector will give notice of his approach by the blowing of a horn. No receptacle will be allowed on the sidewalk, street or public alley.

If service is not rendered promptly on collection day, notify by mail or phone

STREET CLEANING DIVISION, DISTRICT BUILDING
PHONES, MAIN 6000 OR MAIN 2410

FIG. 2. CARD SENT TO HOUSEHOLDERS BY CONTRACTOR PREVIOUS TO ANY CHANGE IN COLLECTION DAYS

Collections of night soil and dead animals are made only on request for such service. The contractor is supplied with a list of requests received, in the form of an order to make the collections, which he is required to return with a statement that the collections have been made, giving the date, or a reason for failure.

INSPECTORS' REPORT—The form, Fig. 4, is a daily report, 11¾x7¼ in., turned in by each inspector and shows

INSPECTOR *B. W. Connelly.*

FIG. 4. REPORT FROM INSPECTOR, SHOWING PLACES VISITED AND CONDITION OF COLLECTION

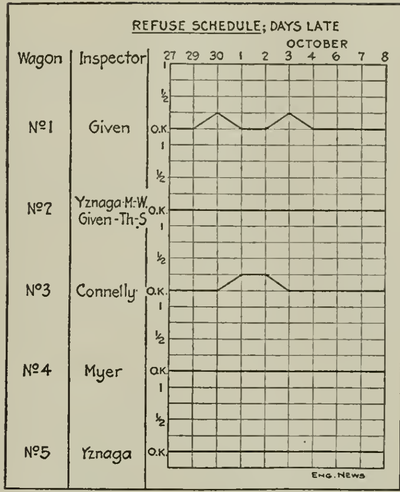

FIG. 5. PROFILE SHOWING CONDITION OF REFUSE WAGONS AS TO THEIR WORKING SCHEDULE

these two records. This profile might well be considered a barometer of the collection service. Thus at certain seasons, a large number of complaints may always be expected, but so long as collections increase and the number of complaints charged to the contractor does not materially increase, the service is probably at a high standard.

In October, 1912, the total ash complaints show a considerable increase on account of cold weather over September, while the collections show an increase of about 5000 cu.yd. The complaints which found the fault with the contractor, however, show only a nominal increase over September.

The refuse profile shows, in May, 1912, the other condition, collections being only slightly more than in April, while complaints increased about 66%, those charged against the contractor, however, increasing about 125%. This indicates the service was at fault, the additional accumulation, due to spring house cleaning, overtaxing the resources of the contractor.

The general upward trend of the collection curve of the refuse profile and the corresponding downward movement of the line of total complaints shows that better service is being rendered.

PROPOSED MUNICIPAL COLLECTION—With a view to obtaining less objectionable, more efficient and more economical services than rendered by contractors, the Commissioners have recommended to Congress that an appropriation of $10,000 be made for the purpose of investigating and reporting on the collection and disposal of city waste, including the preparation of plans and specifications for the construction of disposal plants. Congress has not, as yet, seen fit to make this appropriation.

ADVANTAGES OF MUNICIPAL DISPOSAL WORKS—It is estimated that the contractors for the disposal of city waste have invested in collecting equipment and disposal plants, several hundred thousand dollars, which they must have figured on recovering from the amounts received from the District of Columbia, for the services rendered during the five-year term of their contracts, as these in-

[illegible] will be practically valueless on the expiration of the contracts, if they are not successful in obtaining the same contracts for the next term of five years.

In other words, the District of Columbia is probably paying to the contractors, in addition to the cost of the work and the contractors' profit, the cost of complete disposal plants and collection equipment every five years,

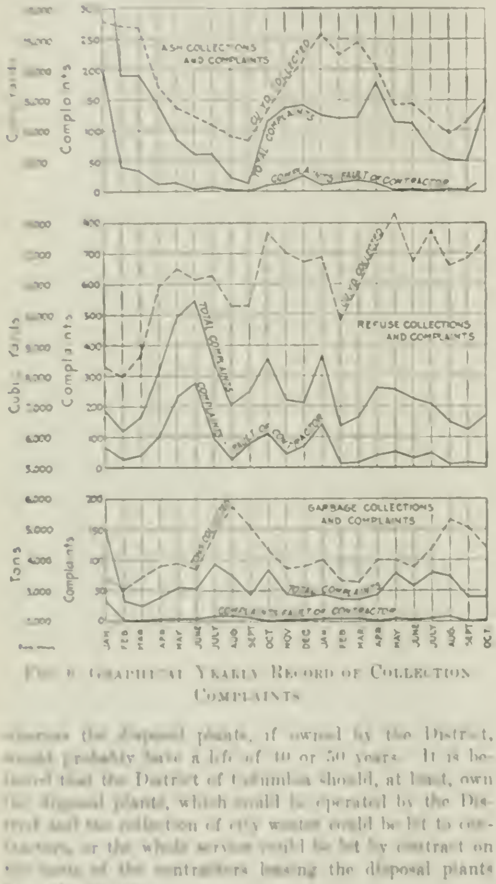

FIG. [illegible] GRAPHICAL YEARLY RECORD OF COLLECTION COMPLAINTS

whereas the disposal plants, if owned by the District, would probably have a life of 40 or 50 years. It is believed that the District of Columbia should, at least, own the disposal plants, which could be operated by the District and the collection of city wastes could be let to contractors, or the whole service could be let by contract on the basis of the contractors leasing the disposal plants from the District.

Electricity in the Anthracite Industry—The introduction of electricity in any great quantity into the mines is not more than [illegible] decades old. The first electrical installation was made in [illegible] by the Lehigh Valley R.R. In 1889 the Thompson-Houston Co. installed a locomotive and a generating station in the [illegible] of the [illegible] Coal & Iron Co. and this locomotive was in continuous service until 1911. The first electric pump was installed in [illegible] and it has been in continuous operation ever since.

The present total capacity of electric generators or [illegible] is [illegible] kw. [illegible] with [illegible] hp. [illegible] by steam [illegible]. Today there are [illegible] miles of wooden pole lines above ground and [illegible] miles of [illegible] lines below ground in the anthracite mines. There are 9[illegible] electric locomotives using an estimated amount of over [illegible] hp. The other electrically operated equipment requires [illegible] hp. for [illegible] and [illegible] machinery, [illegible] hp. for electric hoists, [illegible] for electrically driven pumps, [illegible] for ventilating machinery, [illegible] for lighting and about [illegible] for heating. There are [illegible] [illegible] with individual [illegible] [illegible] [illegible].

Computing Maximum Bridge Stresses by a Maximum-Moment Table

BY J. P. J. WILLIAMS*

The accompanying table has been devised to save a large amount of the labor required to compute live-load stresses in beams and trusses due to Cooper's standard loadings. It gives directly, or by interpolation, the *maximum bending moment per rail produced by E-50 loading* at intermediate points of spans of various lengths. The *number of the critical wheel* which gives the greatest bending moment is also indicated, by black-face figure placed at the upper left when the shorter segment l_1 is the left segment, and at the upper right when l_1 is the right segment (the engines are always assumed to be headed toward the left). The moments are given for every 5-ft. interval along the span, and for span lengths varying by 5 ft. To aid in the work of interpolating, the *change of bending moment per foot change* of distance (l_1) from the nearer support is given by a figure above the moment.

The results can be relied upon as accurate within 1%, and are, of course, available for any specified Cooper's loading by simply multiplying by the ratio of the given loading to E-50. All figures in both table and examples are given in 1000-lb. units.

The well known relation between floor-beam load and two-panel bending moment makes it possible to compute maximum *floor-beam loads* from the values in the table. It will also be proved that there is a definite relation between *maximum shears* in truss panels and maximum bending moments in certain equivalent spans, also between the latter and maximum moments for computing *web stresses* in trusses with inclined chords. The field of usefulness of such a table is thus greatly extended, and includes short methods of computing not only maximum chord stresses but also maximum web stresses in all ordinary trusses in addition to the usual applications to girders and beams.

The method of using the table and applications to definite practical problems will be detailed, and the new relations and formulas fully developed. Incidentally, it will be shown that the limiting value for l_1, the shorter segment of the span, is 11.5 ft. because a constant position of loading and a simple formula will give maximum bending moments when l_1 exceeds that value.

MAXIMUM BENDING MOMENTS

Example 1. What are the maximum E-50 live-load bending moments at 5-ft. intervals in a 50-ft. girder? By entering the table for the known values of segments l_1 and l_2, which for this case are found in the table without interpolation, these results:

Point	l_1 ft.	l_2 ft.	Max. mom. (ft.-kips)
1	5	45	[illegible]
2	10	40	[illegible]
3	15	35	1014
4	20	30	1152
5 (center)	25	25	1150

The value of 1150 for the center section is practically equal to the absolute maximum bending moment near the center. For all spans greater than about 25 ft. in length, the center bending moment is within a small percentage of the absolute maximum bending moment.

*Assistant Professor of Structural Engineering, University of Minnesota, Minneapolis, Minn.

TABLE OF MAXIMUM BENDING MOMENTS FOR E 50 LOADING

Values given in thousand pound-foot units for one rail. Upper figures are differences per foot change in l_1 for interpolation. Blackface figures denote number of critical wheel.

Shorter Segment l_1 (columns); Longer Segment $l_2 = l - l_1$ (rows)

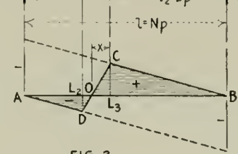

FIG. 3

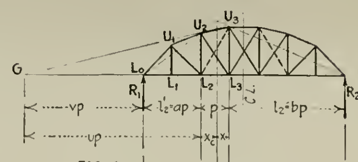

FIG. 4

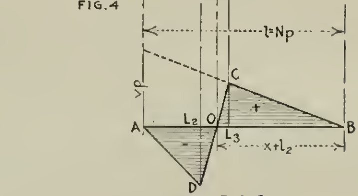

FIG. 5

FORMULAS FOR USE OF TABLE

Max. Moment at C in Beam AB. Fig 1 = M given by table direct

Max. Floorbeam Reaction = $M \frac{l_1 + l_2}{l_1 l_2}$, M taken for l_1 and l_2 equal to the adjoining stringer spans

Max Shear in Truss Panel = $\frac{M}{p}$, M taken for $l_1 = x = \frac{bp}{N-1}$ and $l_2 = bp$, Fig 2

Max. Mom. for Main Web Stress = vM, M taken for $l_1 = x = \frac{bpv}{Nu-v}$, Fig. 4, and $l_2 = bp$

Max. Mom. for Counter Stress = $(u+1)M$, M taken for $l_1 = x_c = p - x$, Fig. 4, and $l_2 = ap$

Example 2. What is the maximum E-50 live-load bending moment at the center of a 76-ft. span? For this case

$$l_1 = l_2 = 38\ ft$$

For $l_1 = l_2 = 35$ *ft.*, $M = 2135$

Add for change in l_1, $3 \times 58 = 174$

Add for change in l_2, $3/_5 \times 270 = 162$

$M = 2471$ *per girder.*

The value of 58 for the difference per foot change in l_1 was obtained from the upper figure 59 found when $l_1 = 35$ ft. and $l_2 = 40$ ft. by allowing for the small difference due to the fact that l_2 is less than 40 ft. The value 270 was easily found by subtracting the two values in the vertical column $l_1 = 35$ ft. for $l_2 = 35$ ft. and $l_2 = 40$ ft. An estimated increase might have been made in this quantity, since l_1 is really 38 ft. instead of 35 ft., but this is generally unnecessary.

LIMITING VALUE OF LEFT SEGMENT—The table was not carried beyond the value $l_1 = 110$ ft. because when the shorter segment l_1 becomes 112 ft. or more the bending moment is maximum for a fixed position of the loading, i.e., engines on shorter segment and head of uniform load 112 ft. from nearer support, as will now be proved. Let

W_e = total weight per rail of the two engines;
= 355 for E-50 loading;
w = uniform train load per rail, per ft.;
= 2.5 for E-50 loading;
W = total load on span l;
y = length of uniform train load on span;
$k = 57.6$ ft. = distance from center of gravity of the two engines to the head of uniform load.

The equation for bending moment M can be written by considering the right segment l_2, the uniform train load covering that segment completely:

$$M = R_2 l_2 - \tfrac{1}{2} w l_2^2 = l_2 (R_2 - \tfrac{1}{2} w l_2)$$

Thus the bending moment is evidently maximum when R_2 is maximum, and

$$R_2 = W - R_1 = W_e + wy - \left(\frac{W_e (k + y) + \frac{1}{2} w y^2}{l}\right)$$

By placing the first derivative with respect to the variable y equal to zero to find the maximum, there is obtained

$$l - y = \frac{W_e}{w} = \frac{355}{2.5} = 142\ ft. \qquad \text{Q.E.D.}$$

Thus whenever l_1 is greater than 142 ft., the bending moments are maximum for a fixed position of the loading, and the value of reaction R_2 due to E-50 loading will be:

$$R_2 = \frac{355 (142 - 57.6) + 2.5 (l - 142) \left(\frac{l}{2} + 71\right)}{l}$$

$$= \frac{[illegible]}{l} + 1.25\, l$$

Therefore

$$M = l_2 \left(R_2 - \frac{2.5}{2} l_2\right) = l_2 \left(\frac{[illegible]}{l} + 1.25\, l_1\right) \quad (1)$$

Example 3. What is the maximum E-50 live-load bending moment at the center of a 300-ft. span? For this case, using Eq. (1),

$$l_1 = l_2 = \frac{300}{2} = 150\ ft. \text{ and } l = 300\ ft.$$

$$M = 150 \left(\frac{[illegible]}{300} + 1.25 \times 150\right) = [illegible]$$

MAXIMUM FLOOR-BEAM REACTIONS

The maximum floor-beam reaction R is obtained from the value of M for l_1 = length of one stringer span and l_2 = length of the adjacent stringer span by the usual well known formula

$$R = M \frac{l_1 + l_2}{l_1 l_2} \qquad (2)*$$

Or, for equal spans,

$$l_1 = l_2 = p$$

$$R = \frac{2\,M}{p} \qquad (2a)*$$

Example 4. Compute the maximum E-50 live-load floor-beam reaction for equal adjacent stringer spans of 25 ft. Read M directly from table with $l_1 = l_2 = 25$ ft. Then, by eq. (2a),

$$R_2 = \frac{2\,M}{p} = 2 \times \frac{1180}{25} = 94.4$$

Example 5. Compute the maximum E-50 live-load column concentration for adjacent viaduct spans of 30 ft. and 60 ft. Read M directly from table with $l_1 = 30$ ft., $l_2 = 60$ ft. By eq. (2),

$$R_2 = M \left(\frac{l_1 + l_2}{l_1 l_2}\right) = 2983 \left(\frac{30 + 60}{30 \times 60}\right) = 149.2$$

SHEARS AND WEB STRESSES (HORIZONTAL CHORDS)

Consider a simple truss span, Fig. 2, of N equal panels, i.e., length $l = Np$, and let

$l_2 = bp$ = distance from right end of critical panel p to right end of span;
x = distance from right end of panel p to the neutral point of no shear in the panel.
$M_s = M$ from the table for $l_1 = x$, $l_2 = bp$;
S = desired maximum E-50 live-load shear in the panel.

The value x can be found either analytically or graphically. By equating to zero the shear in the given panel produced by a single load in that panel, x is found to be:

$$x = \frac{l}{N - 1} \qquad (3)$$

Or the graphical construction of the influence line as in Fig. 3 locates this point of zero shear and the value of x can be scaled.

The influence line for shear in panel $L_2 L_3$ of the truss of Fig. 2 is drawn in the usual way in Fig. 3. The triangular portion OCB would be used to give maximum positive shear, and it is found that for practically all cases the maximum will occur for Cooper's loadings with [illegible] wheels in advance of the point O. Therefore, since this [illegible] shear influence line OCB is exactly similar to a triangular influence line for bending moment at L_3 of a beam $OB = x + l_2$ in length, the ratio of the desired maximum shear S to the maximum bending moment M_s (obtainable from the table) is the same as the ratio of the ordinates to these influence lines. These ordinates at L_3 are:

Shear in panel, $L_3 C = \dfrac{l_2}{l}$

Bending moment at L_3 of OB

$$L_3 C' = \frac{x\, l_2}{x + l_2} = \frac{l_2}{1 + \frac{l_2}{x}} = \frac{l_2}{1 + \frac{l_2 (N - 1)}{l}} = \frac{l_2}{N}$$

*See Johnson, Bryan & Turneaure's "Modern Framed Structures," Part I, p. [illegible].

Since the ratio of these ordinates is $\frac{N}{l}$, the shear S will be:

$$S = \frac{N}{l} M_s = \frac{M_s}{p} \qquad (4)$$

This equation will evidently give results always on the side of safety. For the case of a short through plate-girder with short panels, wheel 1 may be in advance of the neutral point O for panels near the center, but the error is negligible.

Example 6. Compute the maximum E-50 live-load web stresses in a 150-ft. Pratt truss of 6 panels, 28 ft. deep, with horizontal chords. Using the bending-moment table for values M_s and eq. (3)

$$x = \frac{l_2}{N-1} = \frac{l_2}{5}, \text{ and eq. (4) } S = \frac{M_s}{p} = \frac{M_s}{25}$$

the following tabular form of computation can be adopted, noting that i = inclined length of diagonals = 37.5 ft.:

Panel No.	$l_2 = bp$	$l_1 = x = \frac{l_2}{5}$	Ms (from table)	$S = \frac{Ms}{25}$	Stress $= \frac{Si}{h}$ $\frac{37.5}{28} S$	Member
1	125 ft.	25′	5080	203.2	—272	L_0U_1
2	100	20	3370	134.8	+181	U_1L_2
3	75	15	1965	78.6	+105	U_2L_3
4	50	10	938	37.5	+ 50	L_3U_3
		Maximum floor-beam reaction			+ 94.4	$U_1\ L_1$
		Shear in panel 3			— 78.6	$U_2\ L_2$
		Shear in panel 4			— 37.5	$U_3\ L_3$

Main Web Stresses (Inclined Chords)

By an exactly similar analysis a very simple relation between the maximum moment about the moment center for any web member of a truss with inclined chords, and the maximum bending moment at a point of an equivalent beam, can be derived as follows:

Let

M_G = maximum E-50 live-load moment about moment center G of the forces to the left of the section for given web member; (U_2L_3, Fig. 4.)

v = distance in panels from G to end Lo (Fig. 4);

u = distance in panels from G to left end of the critical panel p considered;

x = distance in feet from the right end of critical panel to the neutral point of no stress;

z = lever arm of web member in feet;

M_b = maximum bending moment at L_3 for a span $OB = x + l_2$ in length, i.e., for $l_2 = bp$ as above (Fig. 4) and $l_1 = x$.

The value of x is obtained in the usual way either analytically or graphically. By equating to zero the expression for the moment about moment center G when a single load is in the critical panel, the neutral point is located and the following value for x is obtained:

$$x = \frac{l_2 v}{Nu - v} \qquad (5)^*$$

If preferred, a simple graphical construction as shown in Fig. 4 will give the value of x.*

The influence line for the moment M_G, by which stress in diagonal U_2L_3 of Fig. 4 is determined, is drawn in Fig. 5. As in the case of shear no wheels are found to left of O when maximum stress occurs, and it is evident that the positive area OCB of this influence line is exactly similar to the triangular bending-moment influence line for point L_3 of a span $OB = x + l_2$ in length. For this case, however, the ordinates at L_3 have the new values:

Moment about G, $L_3C = \frac{l_2 vp}{l} = \frac{l_2 v}{N}$

Bending moment at L_3 of OB, $L_3C = \frac{xl_2}{x + l_2}$

$$= \frac{l_2}{1 + \frac{l_2}{x}} = \frac{l_2}{1 + \frac{l_2 (Nu - v)}{l_2 v}} = \frac{l_2 v}{Nu}$$

The ratio of these ordinates is seen to be simply u, therefore to find M_G from the tabular value of M_b and then the main web stress:

$$M_G = u M_b \qquad (6)$$

$$\textit{main web stress } (U_2L_3) = \frac{M_G}{z} = \frac{u M_b}{z} \qquad (7)$$

Example 7. Compute the maximum E-60 live-load stress in diagonal U_2L_3 of a through truss of 7 panels at 28.57 ft. = 200 ft., the truss being 30 ft. deep at U_1, 34 ft. at U_2 and 36 ft. at U_3. Length U_2L_3 = 44.4 ft.

$u = \frac{34}{2} = 17$; $v = 17 - 2 = 15$; $l_2 = bp = 4 \times 28.57 = 114.3$ ft.; $z = 18 \times \frac{34}{44.4} \times 28.57 = 394$ ft.

Then, using eq. (5),

$$x = \frac{l_2 v}{Nu - v} = \frac{114.3 \times 15}{(7 \times 17) - 15} = 16.5 \textit{ ft.}$$

Find M_b from table for $l_1 = x = 16.5$ and $l_2 = 114.3$ by interpolation:

For $l_1 = 15$ and $l_2 = 110$,		2800
Add for l_1	$1.5 \times 180 =$	270
Add for l_2	$\frac{4.3}{10} \times 230 =$	100
	$M_b =$	3170

Then, by eq. (7), stress U_2L_3 for E-50 equals

$$\frac{u M_b}{z} = \frac{17 \times 3170}{394} = +137$$

and for E-60,

$$137 \times \tfrac{6}{5} = +164$$

Example 8. Compute the maximum E-60 live-load stress in the vertical post U_2L_2 of Ex. 7 (Fig. 4). For this member the moment center G is at the intersection of U_1U_2 and L_2L_3, therefore the values of u and v are not the same as in the preceding example although the critical panel remains the same (L_2L_3).

$u = \frac{34}{4} = 8.5$; $v = u - 2 = 8.5 - 2 = 6.5$; $l_2 = bp = 114.3$ ft. as before; $z = 8.5 \times 28.57 = 242.5$ ft. By eq. (5),

$$x = \frac{l_2 v}{Nu - v} = \frac{114.3 \times 6.5}{(7 \times 8.5) - 6.5} = 14.03 \textit{ ft}$$

Compute M_b from the table by interpolation:

For $l_1 = 15$ and $l_2 = 110$		2800
Add for l_2,	$\frac{4.3}{10} \times 212 = 90$	
Subtract for l_1	$0.97 \times 172 = 170$	— 80
	$M_b =$	2720

Then, by eq. (7), stress U_2L_2 for E-50 equals

$$\frac{u M_b}{z} = \frac{8.5 \times 2720}{242.5} = 95.5$$

and for E-60,

$$95.5 \times \tfrac{6}{5} = -115$$

*See Marburg, "Framed Structures and Girders," Art. 138, p. 282 and Art. 194, p. 392.

COUNTER STRESSES (INCLINED CHORDS)

The influence line (Fig. 5) for moment about moment center G to give stresses in the diagonals of panel $L_3 L_4$ (Fig. 4) indicates that the maximum counter stress $L_3 U_4$, which occurs when the negative moment is maximum, is obtained when the engines enter from the left and cover segment AO. It is found that when the criterion for maximum is satisfied no wheels of Cooper's loadings will be in advance of O. Thus the triangular influence line AOD can be used exactly as in the preceding case, noting that the value n now becomes $n + 1$ for the distance in panels from moment center G to *forward* panel load at end of critical panel. Using the same notation as in the preceding case, and, in addition,

$x_c = p - x$ (compute x by eq. (5) or use graphic method).

z_c = lever arm of counter, in ft.,

$l_2' = np = L_0 L_3$ for panel $L_3 L_4$ considered.

M_c = maximum bending moment (from table) at L_3 of span $AO = x_c + l_2'$, for $l_1 = x_c$ and $l_2 = l_2' = np$.

Then by analogy with eq. (6) and (7),

$$(-) M_G = (n + 1) M_c \qquad (8)$$

$$\text{counter stress } (L_3 U_4) = \frac{(-) M_G}{z_c} = \frac{(n + 1) M_c}{z_c} \qquad (9)$$

Example 9. Compute the maximum E-60 live-load stress in counter $L_3 U_4$ of Ex. 7 (Fig. 4). Length $L_3 U_4$ = 16 ft., n = 17 as before, $l_2' = np = 2 \times 28.57 = 57.14$ ft., $z_c = 17 \times \frac{16}{15} \times 28.57 = 388.5$ ft.

$$x_c = p - x = 28.57 - 16.5 = 12.07 \ ft$$

Compute M_c from table for $l_1 = 12.07$ and $l_2 = 57.14$ by interpolation as follows:

For l_2 = 55 ft. and l_1 = 10 ft.,		1005
Add for l_1	$2.07 \times 100 =$	207
Add for l_2	$\frac{2.14}{5} \times 86 =$	37
	$M_c =$	1249

Then by Eq. (9), stress $L_3 U_4$ for E-50 equals

$$\frac{(n + 1) M_c}{z_c} = \frac{18 \times 1249}{388.5} = 458$$

and for E-60,

$$58 \times \frac{6}{5} = 470$$

MAXIMUM CHORD STRESSES

Whenever the moment center for a given chord member lies at or vertically in line with one of the loaded panel points at the ends of the critical panel, the table can be used exactly as for the case of maximum bending moment of a beam to obtain the maximum moment desired. The maximum stress is then found as usual by dividing by the lever arm of the chord member.

Example 10. Compute the maximum E-60 live-load stresses in chords $L_3 L_4$, $L_5 L_6$, and $U_5 U_6$ of Ex. 7 (Fig. 4). Length $U_5 U_6$ = 28.9 ft.

For chord $L_3 L_4$ (moment center U_3), l_1 = 28.57 ft. and l_2 = 171.43 ft. From the table, M is:

For l_1 = 25 and l_2 = 170,		6990
Add for l_1	$3.57 \times 130 =$	460
Add for l_2	$\frac{1.43}{15} \times 1680 =$	160
	$M =$	7610

stress $L_3 L_4$ for E-50 equals

$$\frac{7610}{30} = 254$$

and for E-60,

$$254 \times \frac{6}{5} = 304$$

For chord $L_5 L_6$ (moment center U_5), l_1 = 57.14 ft. and l_2 = 142.86 ft. From the table, M is

For l_1 = 55 and l_2 = 140,		11,580
Add for l_1	$2.14 \times 200 =$	430
Add for l_2	$\frac{2.86}{10} \times 715 =$	210
	$M =$	12,220

stress $L_5 L_6$ for E-50 equals

$$\frac{12,220}{34} = 359$$

and for E-60,

$$359 \times \frac{6}{5} = 431$$

Since this stress $L_5 L_6$ is the horizontal component of stress $U_5 U_6$, we get,

$$\textit{stress}\ U_5 U_6 = 431 \times \frac{28.9}{28.57} = 436$$

Engineering and Temporary Structures for the St. Louis Pageant

Theatrical engineering is a rather limited branch of the profession, the work of which consists largely in the design of special structures and machinery for movable stages, special scenic effects, etc. A class of work which may be included in this branch is the design of the temporary structures for the open-air historical pageant given

FIG. 1. THE STAGE AND AMPHITHEATER FOR THE ST. LOUIS PAGEANT

[illegible]

recently at St. Louis, Mo., the conditions of use and the necessity of ample safety making it desirable to design these structures on engineering principles rather than by rule of thumb. The pageant was given on four days, before great crowds of spectators. The location was in Forest Park, at the slopes beneath the hill occupied by the Art Gallery (the Art Building of the exhibition of 1904), and the seats for spectators were arranged upon the slope of this hill.

The design and construction of the several structures were under the direction of Nelson Cunliff, Superintendent of Construction of the Park Department, and the construction was done by employees of the park department. The work cost about $125,000 and after the closing of the pageant all the structures had to be removed and the park restored to its original condition. The work had to be planned, therefore, with a view to strength, safety and economy.

Timber Stage or Platform

The temporary stage on which the pageant scenes were enacted was built over the water of the lagoon, and was about 520 ft. long by 200 ft. wide. It is shown in Fig. 1. It was supported on piles spaced 7 ft. 9 in. by 8 ft., having a penetration of 7 to 14 ft. and calculated for 7-ton loads by the Engineering News formula. The piles were driven by an improvised piledriver scow with a gasoline engine and 1650-lb. ram (Engineering News, June 11). The same machine was used to pull the piles after the close of the pageant.

On the pile heads (over the 8-ft. spacing) were caps composed of pairs of 3x12-in. planks, across which were laid 2x8-in. joists, 16 in. apart, with a row of 1x3-in. cross bridging in each span (Fig. 2). Upon these was nailed the 2x10-in. floor planking, covered with roofing felt. The sides and rear were protected by hand rails. It was originally considered sufficient to design this for a load of 100 lb. per sq.ft., but Mr. Cunliff raised this to 250 lb. in view of the chances of concentrated loads, the vibration due to the movement of the crowds of performers, and the still heavier vibration due to the passage of artillery and cavalry in certain scenes. A roadway across the stage was covered with tan bark for these latter movements.

At each front corner of the stage was a tower or pylon 45 ft. high, and about 12 ft. square, having four concealed floors for switchboards, telephones (for the stage directors), and for singers. The stage manager considered that it would be necessary to design the floors to carry only a few people, but as a matter of fact it was found that 25 or more people would be on the several floors at one time.

Trussed Timber Wall

In order to render the voices of the performers and singers audible to the spectators a vertical wall or sounding board was erected along the back of the stage, and was painted to form an appropriate background. This is shown in Fig. 2. The central part, 165 ft. long, rose to a height of 40 ft. above the stage (or 50 ft. above the water), and the side section of about 55 ft. rose to a height of 35 ft. above the stage. These great flat surfaces were designed to withstand a wind pressure of 60 lb. per sq.ft., as high winds were liable to occur, and the supporting trusses were designed for 30 lb. wind pressure. At the back of the structure and supported by it were dressing rooms and gangways, so that ample provision had to be made for stresses due to vibration and irregular loading.

The central portion was supported by triangular trusses, resting on the floor, and each having the rear inclined member extended to an anchor pile beyond the stage (Fig. 2). These trusses were spaced $15\frac{1}{2}$ ft. apart, and their inclined members were connected by horizontal struts and three sets of diagonal bracing. Between the vertical front posts were fitted horizontal sticks 2x6 in., 30 in. apart, to which were nailed the 1x10-in. planks forming the face of the sounding board. The truss members were put together with ¼-in. steel connection plates

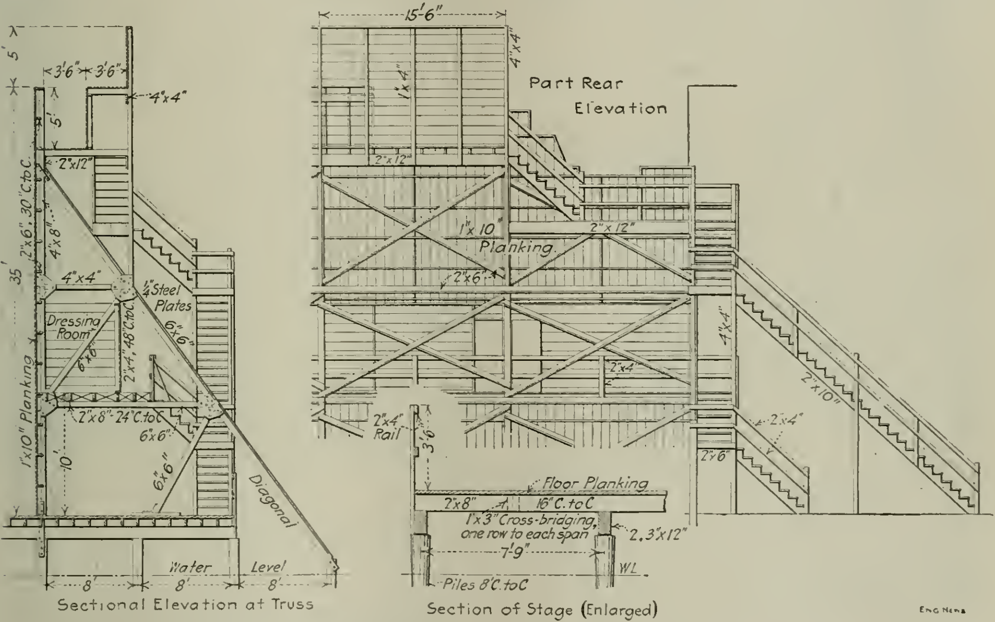

Fig. 2. The 50-Ft. Timber Wall or Sounding Board, with its Truss Supports

punched with 13/16-in. holes for bolts, the burrs being removed.

The side or wing portions of the sounding board were of similar construction, but the trusses carried no floors. They rested entirely on the stage, a 3x12-in. plank spiked

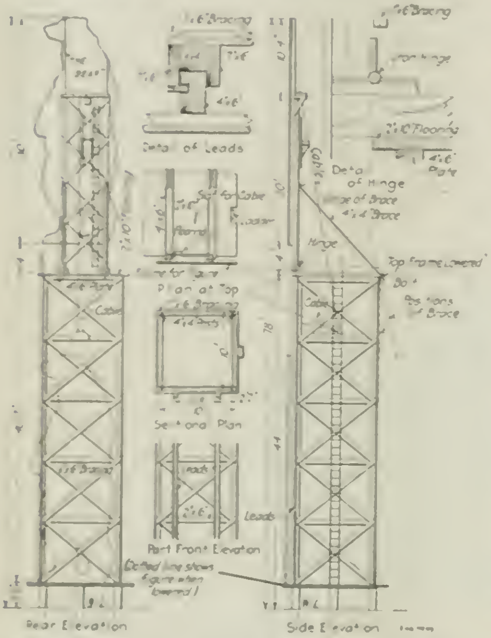

FIG. 3. TOWER AND MOVING FRAME FOR THE "GREAT BEAR" CONSTELLATION

to the joists serving as a sill to carry the rear post of the truss and its bottom strut. These trusses were 17½ ft. apart, connected in the same way as the others.

Timber Tower for the "Great Bear"

One of the illuminated effects was the constellation of the Great Bear, appearing high above the background, the stars being represented by electric lights. The figure of the bear was 30 ft. high, and in its displayed position the top was 78 ft. above the water. As this illumination was to appear only during a part of the performance, the figure had to be made movable or disappearing, and at the same time the possible difficulties due to high winds had to be considered in the handling and supporting of the figure. The figure appears at the right in Fig. 1, and the method of support is shown in Fig. 3.

Behind the stage was built a tower 44 ft. high and 10 ft. square, having four posts 4x4 in., with struts and double bracing of 2x6-in. and 1x6-in. planks on each side. On the front side were two additional posts or leads, with side pieces spiked on to form grooves for the two vertical sticks or runners at the back of the sliding frame of the "bear."

Extending 34 ft. above the top of the tower was a framed panel hinged at the base and having leads connecting with those on the face of the tower (and extending 10 ft. below the top of the tower to form a brace). This frame was supported by four braces, and at its top was a pulley for the cable by which the figure was raised from the base of the tower.

The figure stood normally at the base of the tower. Before the performance it was raised to the full height of the frame, above the tower, and this frame was then revolved backward to a horizontal position. At the proper time it was swung up by block and tackle, the end of the rope being attached to the foot of the hinged frame.

Timber Pyramids

The first scene of the pageant was in the days of the Indian mound builders, and the mounds built by this race were represented by structures forming sections of truncated pyramids (vertical on the rear side). These were of timber framing covered with painted canvas.

The largest of these, shown in the center of Fig. 1, was 32x35 ft. on the base, and 25 ft. high, to a top platform 12x16 ft. surmounted by a temple. The posts were 4x4 in., with inclined corner struts 2x10 in., and stubbing 2x4 in. In this largest structure an elevator was rigged for certain spectacular effects, and this was operated by block and tackle. After this part of the performance the mounds had to be removed from the scene, and for this purpose they were mounted on timber dollies or rollers. These structures had to be of ample strength to support a number of people, and to stand the vibration due to the performers moving about on the top and on the steps on the front slope.

To mask the entrance of the performers from each side of the stage there were wing sections of appropriate scenery, one of which appears between the two rear mounds in Fig. 1. These were large framed panels, supported by braces at the rear, and mounted on large casters with 4-in. wheels to enable the attendants to place and remove them readily.

Wood Bridge

For the service of the pageant a wood bridge having four spans of 15 ft. 6 in. was built across the lagoon, and

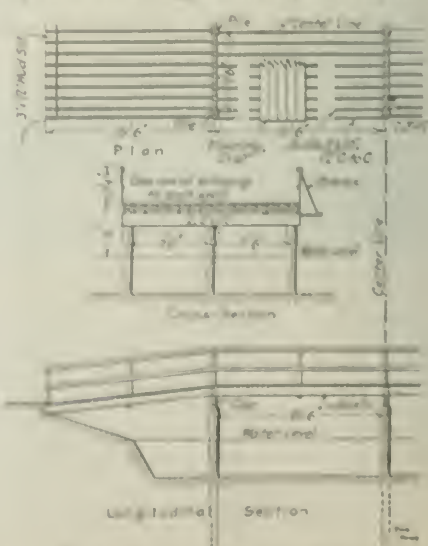

FIG. 4. TEMPORARY TIMBER BRIDGE

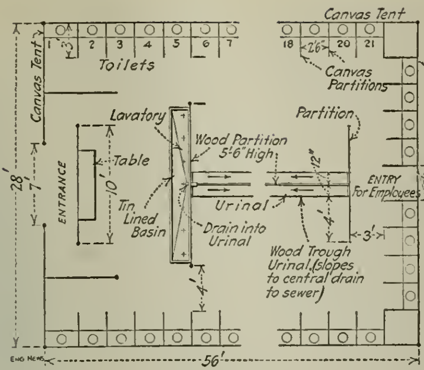

FIG. 5. TEMPORARY PUBLIC-COMFORT STATION IN TENT, ST. LOUIS PAGEANT

was designed for a live-load of 250 lb. per sq.ft. This bridge, Fig. 4, had three bents of three piles each, with caps composed of pairs of 3x12-in. planks. On these were the 2x10-in. joists, 12 in. c. to c., with a line of double bridging between them in the middle of each span. The shore ends of the joists rested on mudsills 3x12 in. The floor was of 2x10-in. planks, and uprights spiked to the outer joists carried the hand railing, the upright in the middle of the span having diagonal braces.

The bridge was built in 2½ days, at a cost of about $200. The materials used were as follows:

Piles (9)	15 ft. long
Floor beams and mud sills, 8 pieces, 3x12 in.	16 ft. long
Joists and flooring, 155 pieces, 2x10 in.	16 ft. long
Bridging, 10 pieces, 1x3 in.	16 ft. long
Hand railing, 28 pieces, 2x4 in.	16 ft. long
Nails, 20d	1 keg

PUBLIC-COMFORT STATIONS IN TENTS

Toilet accommodation for the performers and the crowds of spectators were provided in tents, a dry-pail system being used, as there were no sufficient sewer connections. The urinals, however, were connected to the park sewers. The pails were removed at night by the park department, and were emptied and cleaned at a city sewer about a mile from the site of the pageant.

There were two public-comfort stations (one for men and the other for women) in tents 28x56 ft., arranged as shown in Fig. 5. The arrangement of the women's tent was similar, but in the center were two additional rows of toilet rooms, set back to back, with a 3-ft. passageway between them for the use of the attendants.

For the performers there were four tents 11x21 ft., with a similar arrangement, except that the women's tents (two) had a single row of toilets in the center.

Temporary water mains were laid to serve a number of bubbling fountains and hydrants were provided for fire service.

The American River Irrigation District, to be formed under what is known as the Wright Irrigation District Act of California, has been recommended by a Citizens Investigating Committee headed by J. B. Wrangham, chairman, Fair Oaks, Calif. A report on the project has been made by Stephen E. Kieffer, Consulting Engineer, Mechanics Institute Building, San Francisco. The proposed district would have an area of 18,115 acres located between Sacramento and Folsom, on the north and west side of the American River. The source of water-supply would be the ditch of the existing North Fork Ditch Co. The system of this company includes 25 mi., to quote from Mr. Kieffer's report, "of well-constructed ditch and a system of pressure pipe lines. The ditch would be enlarged and cemented and the pipe lines rebuilt, enlarged and extended." The estimated cost of the "ultimate planned development" is placed by Mr. Kieffer at $687,000, or $37.90 per acre, but this does not include the purchase price of the North Fork Ditch Co. Excluding charges for water rights the estimated annual charge upon irrigated land for water tolls and taxes would be $2.65 in 1915, increasing to $4.59 in 1919, and then gradually increasing. The committee states in its report that adding the cost of water rights and physical properties, which, as we understand, it is proposed to purchase from the ditch company, the total cost of the project would be to $1,087,000, or $58.89 per acre. Taking everything into account, the annual charges for water tolls and taxes and for water rights would be $3.73 per acre in 1915, increasing to $5.11 in 1919. The reports of the committee named and of Mr. Kieffer, including an analysis of the Wright Irrigation District Act, were published as a supplement to "The Fair Oaks Citizen," of Fair Oaks, Calif., for Aug. 20, 1914. Mr. Kieffer informs us that the report was accepted by a mass meeting of the citizens of the district held on Sept. 5 and steps for the organization of the proposed district are to be taken.

Fire and Water Tests of a Metal-Lathe Wall*

A 2½-in. solid metal-lath wall of construction shown in the accompanying cut was erected in a fire-test house at Columbia University, New York City, and subjected to an average temperature of 1700° F., for 2½ hr., as measured by three thermo couples connected to a Le Chatlier pyrometer. At the end of this period a 1⅛-in. stream of cold water at hydrant pressure (25 to 30 lb.) was directed against the partition for 2½ min. Neither the fire nor the water did sufficient injury to the wall to destroy its stability or fire-resisting quality.

The partition wall tested was 14.5x9.5 ft. high, and the studding was of 1-in. channel-iron weighing 0.76 lb. per lin.ft. and set 12 in. c. to c. The lath was 24-gage expanded metal lath painted on both sides, and weighing 3¼ lb. per sq.yd. It was sewed to the studding with No. 18 annealed galvanized tie-wire.

The first, or scratch, coat of plastering was 1 part portland cement, $\frac{1}{10}$ hydrated lime and 2½ sand, by volume. About 1 lb. of long cattle hair per 1 cu.ft. of cement was used. Two similar coats, with the omission of the hair, were then applied; and finally a coat of 1:2½ mix was put on.

The heat developed a number of cracks in the exterior face of the wall within the first 10 min. of the test. No cracks were noted on the inside during the first 1½ hr., when four cracks averaging about 2 ft. in length appeared. After a total period of 2 hr. 40 min., the inner surface of the wall became crazed with innumerable hair cracks extending in all directions. The maximum opening was only $\frac{1}{16}$ in. deep.

The partition started to deflect inward almost immediately after the test was started; the maximum deflection was $4\frac{3}{16}$ in. After cooling the wall with water, the deflection was $2\frac{7}{16}$ in. The application of water washed away a large portion of the finish coat of plaster, and considerable of the second coat. No metal was exposed.

No fire, smoke or water penetrated the partition and after it had dried out, it was firm and gave a good ring when struck with a hammer.

*From a report of a fire and water test upon a fireproof partition, made at the Columbia Fire Testing Station, New York City, on July 17, for the Associated Metal Lath Manufacturers.

Methods and Equipment for Applying Lime Water at the Columbus Water-Purification Works

By Charles P. Hoover*

In the use of lime for water treatment at Columbus, Ohio, various methods for applying the lime water have been tried, and improved methods and apparatus have been adopted. This article, which is supplementary to one on "The Use of Lime in Water Purification," published by the present authors in ENGINEERING NEWS of [illegible] 1914, outlines earlier experiences and describes present methods and apparatus employed at Columbus.

It may be explained in passing that the water of the Scioto River is treated with lime, soda ash and sulphate of alumina to soften and purify it, and after the various chemicals have been given an opportunity to react the water is passed through mechanical filters. This article is concerned only with the methods and apparatus used in applying the lime.

Methods of Applying Lime Water

The following methods of applying lime to water have received considerable attention:

(1) Treating the water with a saturated solution of lime water (64 grains CaO per gal.).

(2) A continuous feed of standard strength solution of milk of lime.

(3) Adding weighed amounts of lime at definite intervals of time.

SATURATED LIME WATER—When the Columbus plant was first started it was thought advisable to apply lime to the water as saturated lime water, for the following reasons:

(1) Lime water being a true solution could be more readily applied in uniform quantities than milk of lime.

(2) The feasibility of thoroughly mixing raw water with milk of lime in large quantities was questioned. It was thought that the raw water and the milk of lime would not be adequately mixed, resulting in a marked loss in softening efficiency, owing to the fact that the suspended particles of lime (calcium oxide) would become coated with precipitated carbonate of calcium and magnesium hydrate, thereby lessening [illegible].

According to this theory, the plant was equipped with lime saturators and an attempt was made to apply the lime as saturated lime water. After being pumped into the [illegible] of the head house, the water was divided. One portion passed over a weir, milk of lime was added and it was then passed into the lime saturators, designed to make a saturated lime water carrying about 76 grains $Ca(OH)_2$ in solution and about 15 grains in suspension [illegible].

[illegible] and adjustable weirs were provided, regulating the flow of raw water to the saturators from a minimum of [illegible]% to a maximum of [illegible]%. More than [illegible] [illegible] was [illegible]. Considerable lime ([illegible]) was lost in the sludge which collected in the bottom of the saturators. Sludge taken from these deposits contained as much as 70% CaO, hence, after a short time, the attempt to make saturated lime water was abandoned.

STANDARD SOLUTION OF MILK OF LIME—Since abandoning the procedure of treating with saturated lime water, milk of lime has been added to the raw water, either at the entrance of the saturators which are now used as mixing tanks or at the entrance of the baffled mixing tanks. It is fed automatically in proportion to the quantity of water pumped. This is accomplished by means of an automatic chemical feed regulator.

The method of handling lime in bags was abandoned in February, 1913, and an entirely new equipment was installed for storing and handling the material. In this new method of procedure, as now practiced at the Columbus water-softening and purification plant, crushed lime is elevated into storage bins, and from the storage bins the lime drops into automatic weighing scales, definite amounts of lime being discharged from the scales into the slacking tanks at predetermined intervals of time. (The storage bins and weighing apparatus are described in some detail further on.) The slacked lime is discharged from the slacking tanks into the chemical solution tanks below, and milk of lime of required strength (3 or 4% solution) is made by the addition of water. The paddles installed for the purpose of keeping the milk of lime thoroughly stirred have proven inadequate, and jets of compressed air have been supplemented at three points near the bottom of each solution tank. Tests made upon portions at 15-minute intervals, from the time the solution tank first begins to discharge until it is empty, show that the solution varies in strength from about 2 or 3% each side of the mean.

ADDING WEIGHED AMOUNTS OF LIME AT DEFINITE INTERVALS OF TIME—At the St. Louis water-purification works, lime is weighed by automatic weighing scales into slacking tanks, and discharged from the slacking tanks directly into the water. This plan may very easily be adopted at Columbus by simply bypassing the present lime-solution tanks.

The advantages of this plan are:

(1) No chemical feed regulator is required other than the automatic weighing scales.

(2) No chemical solution tanks are needed, thus the paddles and air necessary to keep the milk of lime in good suspension may be dispensed with.

But in order for this plan to work out successfully it is necessary that the quantity of water to be treated with lime be delivered to the plant at a uniform rate.

PIPING MILK OF LIME—Much trouble was experienced at Columbus in transporting the lime milk from the orifice box to the point of application to the water. Heavy deposits of lime formed in the pipes and stopped them up. This was overcome by connecting an ejector into the pipes just below the chemical feed regulators.

HYDRATED VS. QUICKLIME—The work of sacking lime [illegible] proved to be a very disagreeable job, especially in hot weather, on account of the lime dust sticking on the sweaty hands and faces of the men. The sticking of lime dust often resulted in severe burns and sores. It was thought that the disagreeable feature attending the use of quicklime might be overcome by using hydrated lime in its place.

Several carload lots of hydrated lime packed in [illegible] valve-type paper bags were received and used. This material was easily stored because the bags were square and could be closely packed, and as the lime had its affinity for water satisfied there was no trouble from swelling and [illegible]

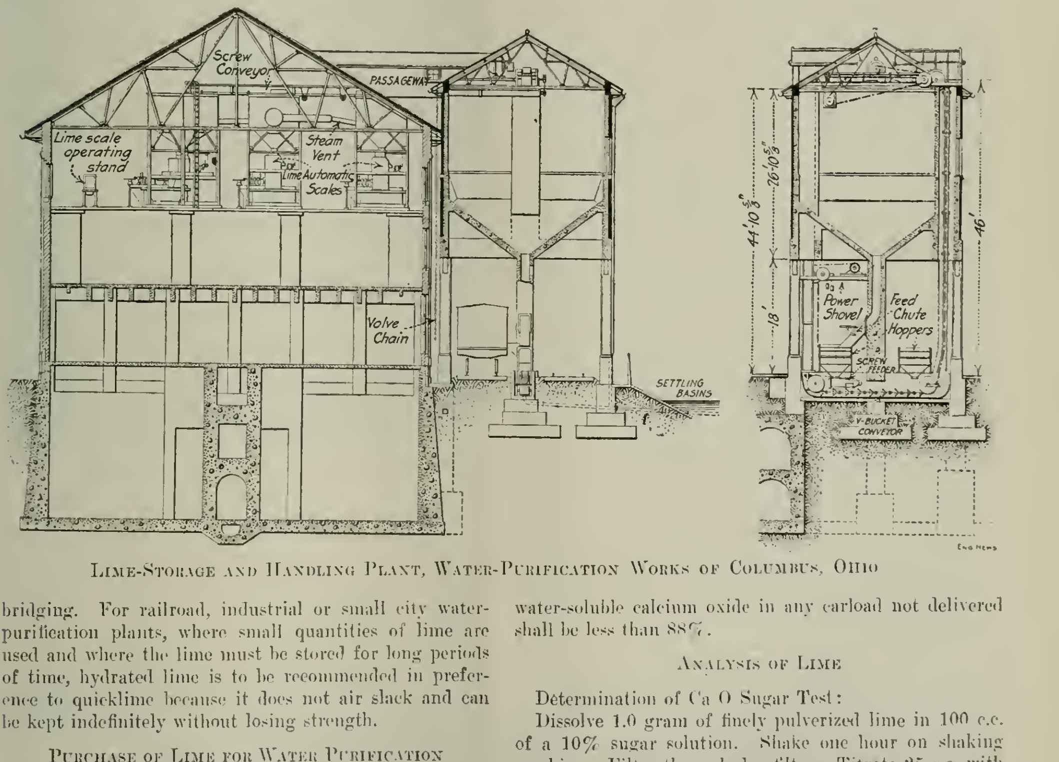
*[illegible] Water-Softening and Purification [illegible] Columbus, Ohio. [illegible]

bursting of bags. The material could be kept indefinitely without losing strength because it packs into a dense mass, rendering the penetration of carbon dioxide very difficult. However, it did not prove economical or satisfactory to handle, and its use was abandoned for the following reasons: Hydrated lime costs more than quicklime. If the hydrated lime is shipped to the plant where it is to be used the consumer must pay freight on a large per cent. of water, aproximately 30%. It is very difficult to apply hydrated lime to water on a large scale. One of the disagreeable features of using hydrated lime in large quantities is that it "flies" badly, scattering dust through the plant The dust gets into the eyes, noses and throats of the men handling it. Hydrated lime, according to Monfort, cannot be successfully fed through an orifice, and if fed into automatic scales there is trouble due to more frequent cleaning of the sedimentation basins.

In paying for lime the contractor should be paid a bonus when the calcium-oxide content of the lime exceeds the guarantee, and a penalty should be extracted when the percentage of the calcium oxide is below the guarantee.

Specifications for Lime Used at Columbus

For any carload of lime containing 88% of water-soluble calcium oxide, the city will pay to the contractor the price per ton stated in the proposal. It is hereby agreed that the city shall pay a bonus of 1½% of the contract price per ton for each 1%, by which the water-soluble calcium oxide in any carload lot delivered shall exceed 88%, and shall exact a penalty of 1½% of the contract price per ton for each one per cent. by which the



Lime-Storage and Handling Plant, Water-Purification Works of Columbus, Ohio

water-soluble calcium oxide in any carload not delivered shall be less than 88%.

bridging. For railroad, industrial or small city water-purification plants, where small quantities of lime are used and where the lime must be stored for long periods of time, hydrated lime is to be recommended in preference to quicklime because it does not air slack and can be kept indefinitely without losing strength.

Purchase of Lime for Water Purification

The value of lime for water-purification purposes depends upon its percentage of water-soluble calcium oxide. The reactions already given show that it is the calcium oxide in the lime that absorbs the carbonic acid in the water and precipitates the magnesium. The percentage of inert material, such as carbonate of lime, cinders, unburned and overburned lime, magnesium, alumina and silica, increase or decrease in the same proportion as the calcium-oxide content increases or decreases, and the presence of this inert material detracts from the value of the lime because it increases the bulk, thus increasing the cost of handling and storing it. The inert material being insoluble in water, causes trouble by clogging the slacking tanks and orifice boxes and necessitates

Analysis of Lime

Determination of Ca O Sugar Test:

Dissolve 1.0 gram of finely pulverized lime in 100 c.c. of a 10% sugar solution. Shake one hour on shaking machine. Filter through dry filter. Titrate 25 c.c. with N/10 H_2SO_4, using Phenolphthalein as indicator. The burette reading multiplied by 1.122 = % Cao. (The 10% sugar solution should be made with cool, freshly boiled distilled water.)

Lime-Storage Bins, Conveying and Weighing Apparatus

As has been explained, the lime used at the Columbus plant was at first handled and stored in canvas bags. Finding this unsatisfactory, the lime was bought in bulk in carload lots, bagged at the purification works and used shortly after bagging, the lime contractor varying his weekly deliveries to suit the demand as determined by the changes in the character of the water. Regulation of the

supply proving difficult, and the operations also proving troublesome and expensive, the writer and C. J. Clarke, engineer in the water-works department, were instructed to devise new means for handling the lime. Their plans and specifications were adopted, after having been checked by R. S. Jones, of Columbus, who suggested some changes. The storage-bin, conveying equipment and automatic weighing scales were described by the writer in the annual report of the Columbus Division of Water for 1913, from which the remainder of this article is reprinted.

STORAGE BIN—This consists (see sections of hopper and building) of a concrete hopper, 25½ ft. square, with bottom slopes of approximately 38 degrees with the horizontal, heavily reinforced to take the direct pull due to the weight of the lime and the horizontal thrust due to the bulging effect. The main weight is carried on four reinforced-concrete beams, supported in turn by eight columns with flared footings, which take bearings on the solid gravel under the track bed. The center column takes part of the load of the hopper and is cored inside with an 18-in. square opening used as a chute to reclaim lime from the storage bin and deliver it by means of the elevator and conveyor to the tanks in the headhouse.

The lime may be taken directly from the cars to the tanks without passing into the storage bin. The storage bin has a capacity of 220 tons of lime, or about 22 days' supply, which gives ample storage for any emergency.

CONVEYING EQUIPMENT—The conveying equipment consists of a continuous V-bucket conveyor and elevator with a capacity of 50 tons per hr., running in a concrete trough between the tracks and through chutes each side of the bin, so that it is inclosed throughout its entire length. The lime is discharged from this elevator into a 12-in. screw conveyor which extends into the roof of the head house and discharges into the top of three tanks which are supported on the third floor of the head house on angle columns and extend through the ceiling into the roof space above.

The V-bucket conveyor and the screw conveyor are operated by an [illegible] Westinghouse direct current, 220-volt motor, situated in the roof of the storage bin. The tanks are constructed of ¼-in. steel plate, are 8 ft. square, with hopper bottoms, and have a combined capacity of approximately [illegible] tons, or about two days' supply.

Lump lime, averaging about 2 in. in size, is fed from the tanks into automatic weighing scales, which automatically weighs the lime into the slacking tanks. The slaked lime discharges from the slacking tanks into the lime-solution tanks below. Milk lime, of required strength, is made by the addition of water. The milk of lime is kept well stirred by means of paddles and jets of compressed air and is measured into the water by a chemical feed apparatus. Later it is planned to pipe the slacked lime directly from the slacking tanks into the water, thus bypassing the lime-solution tanks and the chemical feed regulator.

The writer is indebted to W. N. Goodman for the following description of the automatic scales:

AUTOMATIC SCALES—The three automatic scales are [illegible]

charged is placed in the weight box, or the excess of weight over 75 lb. can be added by a sliding counterpoise working on the graduated lever.

The lime is fed to the weigh hopper of the scale down a sloping chute in which is placed a reciprocating plate feeder to keep the lime from blocking. This feeder is in action only while the scale is filling. It is motor-driven by an electric motor, and as soon as the scale has received its load the motor automatically stops.

After being fed down the inlet chute the lime passes through a gate of the undercut type. When the weigh hopper has received four-fifths of its load the gate partially closes, the last one-fifth being dribbled into the hopper. When the exact amount has been received into the hopper, the gate closes and is locked by a toggle mechanism. The scale hopper holds the load until it is time to discharge it.

The time of discharge of the three scales is governed by a very ingenious electric clock device specially designed for this job. The scales are connected electrically to the clock and so arranged that one, two or three scales may be discharged as desired merely by throwing in the corresponding switches. Supposing Scale No. 1 is required to discharge 100 lb. every minute, it is set to weigh exactly 100 lb. and a minute disk is placed on the clock face. At every one minute interval the clock movement closes a switch which is connected to the scale by means of a solenoid; this solenoid discharges the scale by allowing the weigh hopper door to open. After discharging the load the hopper door closes again and locks itself. In doing so it opens up the inlet gate and automatically starts another weighing, which will be discharged at the right time. The clock can be set to weigh any number of discharges, from 60 per hr. down to 1 per hr.

Each scale is equipped with an automatic stop-counter device, so that when a certain quantity of lime is required to be weighed into the slacking tank the counter is set to the number of drafts required, and when that quantity has been weighed the scale will stop automatically. The scales are very accurate, much more so than any hand-weighing methods.

In order to get rid of the steam arising from the water in the slacking tanks, pipes are connected to a suction fan, which draws nearly all the steam away from the scales. To prevent dust and steam from clogging the operating levers of the scales, all of the levers are placed outside of the scale proper, which is inclosed in a heavy cast-iron dust-proof casting. All of the pins in the scales are made of phosphor bronze and the bearings in which these pins work are bronze bushed, so there is no chance for corrosion to affect accurate and continuous work. The clock device is arranged in a dust-proof lock-up casing, with glass doors, thus preventing tampering.

UNLOADING LIME FROM CARS—A power shovel for unloading lime from cars into the hopper of the conveyor is located just under the storage bin and supported on the columns. It is operated by a separate 5-hp., 220-volt Westinghouse motor, and has unloaded a [illegible]-ton car in about three hours, two men being necessary to do the unloading. The total contract price for the bin and equipment complete was $17,[illegible]. Extras were $1303.

The new installation was put in service Feb. 5, 1913, and it has operated successfully from the start.

COST OF OPERATION—A cost system is kept at the plant and the cost of every job or operation is known. A comparison of the cost of unloading, sacking and handling chemicals during the year 1912, the year before the new equipment was installed, and the cost of handling chemicals during year 1913 is of interest.

In 1912, 5774 tons of chemicals were used and 28,[illegible] hr. of labor are charged against the handling of this material or 4 hr. and 54 min. for each ton handled.

In 1913, 7701 tons of chemical were used and [illegible] hr. of labor are charged, or 3 hr. and 23 min. per ton.

This represents a saving of 1 hr. and 31 min. on each ton of chemical handled. At the present time the labor cost of handling chemicals amounts to approximately [illegible] per hour, so that the saving of 1 hr. and 31 min. is equivalent to approximately [illegible] per ton.

Figured on this basis the saving effected during the year 1913 by the introduction of this new equipment amounted to $[illegible].

Methods of Construction of the Grand Mere Hydro-Electric Plant, Quebec

One of the largest hydro-electric plants in Canada is now nearing completion at Grand Mere, Quebec, 90 miles northeast of Montreal. At this point, the St. Maurice River which drains an area of some 17,000 sq.mi. lying

Fig. 1. The Rocky Island Which Gave Grand Mere Falls Its Name

north of the St. Lawrence, crosses a barrier of hard Laurentian rock and falls about 45 ft.

The Laurentide Co. has for years had in operation at this point one of the largest pulp and paper manufacturing plants in Canada, utilizing, however, only a part of the available power. Two years ago, the company determined to proceed with the work of power development at this point on a large scale, and plans for the work were prepared by Geo. F. Hardy, Consulting Engineer, 309 Broadway, New York. On Jan. 16, 1913, a contract for the construction of the entire work was made with the H. E. Talbott Co., Engineers and Contractors of Dayton, Ohio.

At Grand Mere Falls, the St. Maurice River is divided into two channels by a large island of hard rock covered with a heavy growth of trees.

On the western channel the original power plant and paper mill were constructed. In the project for utilizing the entire flow of the river, it was necessary to cut this rocky island down to water level to obtain a sufficient length of spillway for controlling the water level above the falls in the flood season.

It was a detached pinnacle of this island whose rugged profile gave Grand Mere its name, as may be understood by reference to Fig. 1, showing a winter view of the "Grandmother." While this ancient landmark had also to be removed in building the new power plant, the directors of the Laurentide Co. desired that it should be preserved, and the contractor was required to take it down piece by piece and reërect it on a pedestal near the company's office. The total mass moved represented five or six hundred tons of rock.

While the natural fall was about 45 ft., the dam now under construction will so raise the level of the water above the falls as to give a total head of 76 ft. The still water, navigable by motor boats, will extend about 75 miles upstream to La Tuque.

The advantage to the power plant of the great storage thus created for carrying peak loads will be obvious. It may be noted in addition, that the Provincial Government of Quebec has made plans for transforming a labyrinth of lakes on the upper reaches of the St. Maurice into great storage reservoirs, which will enable the spring floods to be impounded and released during low-water periods.

The designs for the hydro-electric plant at Grand Mere provide for the development of 180,000 hp. by nine turbine-generator units of 20,000 hp. each. These turbine-generators are to be located in a power house which will form a barrier across the west channel of the river.

Fig. 2. Beginning Work at Grand Mere Falls, July 20, 1913.
(Old paper mill at left. Upper coffer-dam completed on top of old paper-mill dam. Work started on coffer-dam across tail race.)

The east channel of the river is to be closed by a concrete spillway dam, which will extend across the island.

The construction work had to be carried out without interrupting the operation of the present power plant and paper mills located close to the west bank of the river. This was not wholly disadvantageous, however, since the large proportion of the river's flow diverted through the turbines of the present paper mill, made so much less water to be taken care of in construction.

To lay dry the power-house site, the water was shut off from above by a low coffer-dam on top of the paper company's old wooden crib dam. This was comparatively easy. Then a coffer-dam about 600 ft. long was carried across the tailrace in an average depth of some 20 ft. of water. This dam was made up of wooden cribs with 12x20-ft. pockets filled with stone, the outside covered with sheet piling and canvased to make it water-tight. The rock bottom on which this coffer-dam was placed was very irregular and was covered with a deep deposit of bark, logs, gravel and boulders, which had to be dredged out before sinking the cribs.

As stated above, the contract for the work was signed on Jan. 16, 1913. The early months of the year were spent by the contractor in getting his force and plant onto the ground and organized. The coffer-dams could not be built until after the spring floods in May, when the melting snow pours into the upper reaches of the river. Between that time and the latter part of August, however, the coffer-dams were completed and pumped out. By the end of December, the rock excavation had been completed over the whole power-house area, about 400x160 ft., and in the tailrace below the power-house area, as shown in the accompanying figure. The draft-tube forms had been placed and the concrete had been poured for the entire lower portion of the power house and the section of dam adjoining, bringing the structure to the elevation of the scroll case and above the normal level of water in the tailrace. The pumping plant and lower coffer-dam had also been removed.

Work on concrete laying could not be resumed in the spring till after the flood season in May. Fig. 5 shows the

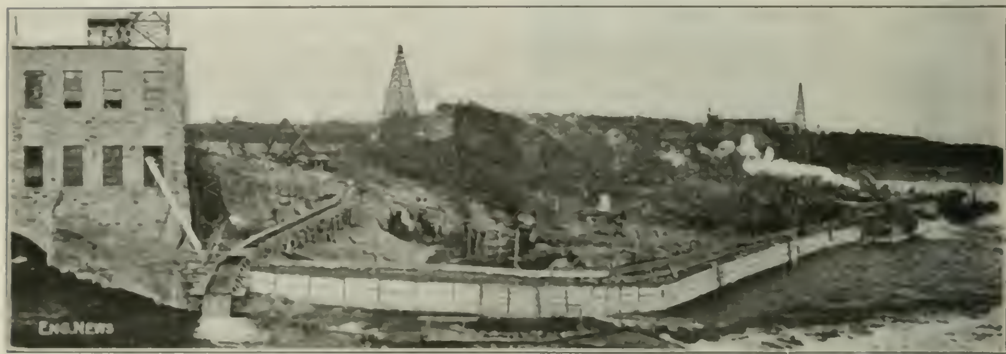


FIG. 3. TAIL RACE COFFER-DAM, COMPLETED AND PUMPED OUT, AUGUST 15, 1913

flood pouring over the power-house foundation on May 27, 1914. Fig. 6 shows the power-house foundation on June 11, after most of the flood had subsided.

Work was now pushed with the utmost rapidity. Hoisting towers and concrete distributing spouts were erected and the placing of forms and of reinforcement previously made ready and the pouring of concrete went on night and day. Fig. 7 is reproduced from a photograph of the power-house work taken on July 24. A month later, the steel frame of the power house was nearly completed and the concrete had been carried up to the floor level of the generator room, while the work of concreting the partitions between the gate chambers was far advanced. Besides the work on the west channel, the dam across the east channel had been completed for about half its length and most of the island had been excavated down to water level, the rock removed being used for concrete.

It will be of interest to note the plant, methods and organization by which the work has been carried forward with such rapidity. The accompanying general plan of the work, Fig. 8, will assist in making the operation clear.

In the first place, it is well to emphasize that the problem of chief magnitude on such a work is the problem of rapid and economical conveying and placing of material. The entire work involves the excavation of 110,000 cu.yd. of rock and 810,000 cu.yd. of earth, placing 170,000 cu.yd. of concrete with 1000 tons of reinforcing steel and erecting 3000 tons of structural steel. The lumber, cement and steel which have to be brought to the work aggregate over 2000 carloads.

FIG. 4. DRAFT TUBES COMPLETED AND ROCK EXCAVATION IN TAIL RACE IN PROGRESS, NOVEMBER, 1913

The river at the falls flows in a narrow gorge with steep banks, and available room on the west side was already occupied by the paper company's plant. Material had to be received and stored on the banks of the river therefore high above the site where it was to be finally used. The cableway system was adopted to transport the material from this point to its place in the works, and it is difficult to see how any other system could have compared with it for economy or speed.

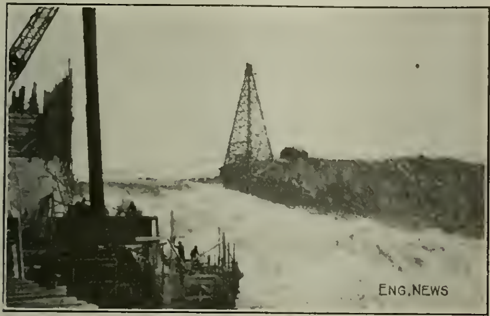

Fig. 5. Spring Flood Going over Completed Lower Section of Power House, May 27, 1914

Fig. 6. Lower Part of Power House after Partial Subsidence of Flood, June 11, 1914

(Inclines are the lower parts of the penstocks above the turbines.)

Sidings were built from the railway to the site on both sides of the river, one on the west side reached a sand deposit on the west bank below the falls from which sand for the work was obtained. The sand was loaded on railway cars by a clam-shell bucket handled by a locomotive crane. A clam-shell bucket and crane was also used to transfer the sand from the cars to storage bins, from which it is drawn for use as required.

On the immediate site of the work, the materials were hoisted and conveyed by four Lidgerwood cableways. One of 7 tons capacity and 1650-ft. span extends from the main concrete mixing plant over the power house and part of the dam, and is used chiefly for transporting concrete from the main mixing plant to the work. A smaller cableway of 3 tons capacity and 600-ft. span, on the west side of the river, carries materials for concrete to an auxiliary mixing plant on the roof of the paper-mill building on the west bank of the river close to the power-house site from which mixer the concrete is chuted where desired. Another 7-ton cableway of 1125-ft. span is stretched over the island. Skips of rock loaded by the excavating force on the island are carried on cars running on transverse tracks to a point beneath the cableway, and are then hoisted by the cableway, carried to the east bank and dumped on an inclined platform from which the rock slides into the crushers. A fourth cableway will handle concrete for the completion of the spillway over the east channel.

All but one of these cableways are operated by electric motors. Current for these and other motors on the work and for lighting the entire plant is supplied from the hydro-electric plant at Shawinigan Falls, four miles below on the St. Maurice River. The 50,000-volt current is received at Grand Mere in a transformer station where it is stepped down to 2210 volts by a bank of three 1000-kv.-a. transformers. Part of this 2240-volt current goes to a bank of three 100-kw. transformers which reduce it to 370 volts at which pressure it goes to a rotary converter for reduction to 600-volt direct-current for operting d.c. motors.

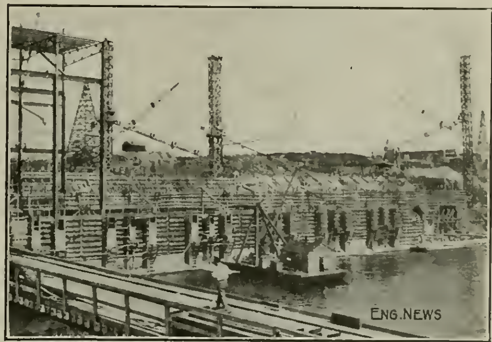

Fig. 7. Progress of Concreting and Steel Superstructure Erection, July 21, 1914

Another part goes to three 75-kw. transformers which deliver 450-volt current for a.c. motors. The current for lighting passes through a 25-kw. transformer and is delivered at 230-115 volts.

The concrete bucket used on the long span cableway is shown in Fig. 9. The bucket is dumped by letting the two overlapping hinged leaves which form the bottom of the bucket swing apart. These leaves are held closed by the tension on the ropes by which the bucket is traversed on the cable, and by slacking on these ropes the cableway operator can dump the bucket at any point.

This system gives very rapid operation, and the bucket empties itself clean. With the bucket traversing a distance of 1100 ft., 187 buckets of 2.4 cu.yd. each were poured in a ten-hour shift.

For distributing concrete in the power-house construction, extensive use is made of hoisting towers with chutes and gates, as may be seen in the accompanying figures. Small electric trolley hopper cars are used for carrying the concrete from the hopper into which the cableway deposits it to the foot of the hoisting towers. Portable mixers are used on parts of the work not easily reached by the cableways. During the month of July about 21,000 cu.yd. of concrete were placed in the work.

In order that the rate of progress of the work might be carefully watched, a large diagram was plotted at the outset with lines showing the expected rate of progress on ex-

eration, concrete laying, steel erection, and other principal items of work. This diagram is posted on the wall of the main office and upon it is plotted daily the amount of work accomplished. By comparison of the lines of expected and of actual progress, it is seen at a glance whether the work is proceeding faster or slower than is necessary to reach completion at the time originally planned. Daily reports are also filed, showing the output of each principal piece of plant, bucket of concrete handled, skips of rock transported, cars of sand delivered, etc.; also the hours of time during each of the machines was shut down, with the reason why the shutdown was necessary.

The main stone-crushing plant, to which the stone ex[illegible]

concrete was carried up, the forms were ready for setting.

Besides the work on the dam and power-house construction, a large tract of land next the river bank above the dam had to be raised some 12 to 15 ft. to bring it above high-water level when the dam is completed. This tract is used by the paper company for storing its year's supply of pulp-wood. It may be explained that the wood used for pulp is floated down the St. Maurice River from various lumbering operations on the head waters. Most of this wood comes down the river during the season of high water in the spring, and is cut into 2-ft. lengths, barked and put into storage to be used as needed. Two lofty steel towers, 180 ft. high, carry by light suspension members, a latticed truss, 600 ft. long. There is also a head tower 90 ft. high and an inclined truss 600 ft. long. These trusses carry an endless-chain conveyor, which transports the barked pieces of pulp wood and drops them on the storage pile.

This structure was erected last winter by the Talbot Co., which also raised the level of the wood-storage yard around these towers, bringing in for that purpose some 200,000 cu.yd. of earth on dump cars loaded by steam shovel.

The contractors have had, at times, a force of some 1100 men on the work, and the care of this force was as important a feature in securing rapid and efficient work as the provision of efficient machinery. Nearly all the foremen and even some of the workmen have been employed more or less continuously by the contracting company on various construction jobs since 18[illegible].

As is usual on large construction operations, the working force is made up of a mixture of many nationalities, mostly brought in from outside. The local French Canadians were little used in construction work of this sort and comparatively few were employed. A medical service was maintained on the work and gave a careful physical examination to every applicant for employment. A considerable number, found to be infected with dangerous or infectious diseases, were rejected and only those were accepted who were found physically fit for their jobs. The physicians had also to care for those hurt by accident or attacked by disease.

The water of the St. Maurice River is polluted by drainage from settlements above, and cases of typhoid in the locality are common. The entire working force, therefore, was supplied with water carried from large springs in the vicinity. To reduce the risk of accident to water boys

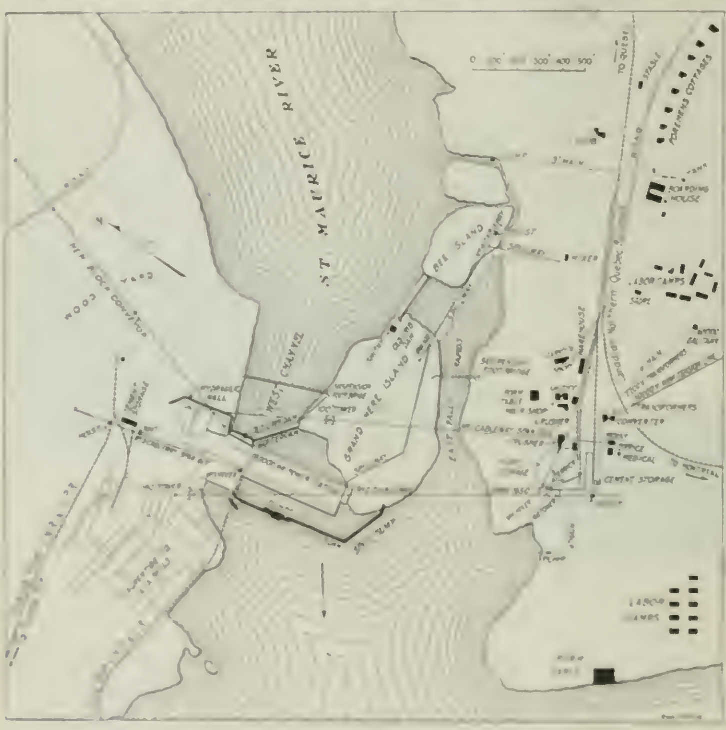

FIG. 3. GENERAL PLAN OF WORKS FOR CONSTRUCTION, GRAND MERE HYDRO-ELECTRIC PLANT

[illegible] from the island is delivered, crushed, in a large gyratory crusher, with a small [illegible] crusher taking care of [illegible] pieces rejected by the screen below the main crusher. Belt conveyors are used for carrying the crushed stone and also for the bags of cement from the cement storehouse (75,000 bbl. capacity) to the mixer. A conveyor is operated at the sand and gravel pit for taking cobbles and stones rejected by the screens through which the gravel is passed.

A carpenter shop, with band-saw, [illegible] and other woodworking tools, was installed to carry out the form work; and to facilitate the laying out of the large and complicated forms necessary for the draft tubes, scroll cases, etc., a large [illegible] form table was built outdoors. The form work, of course, was done in advance so that as fast as the

Fig. 9. Bottom Dumping Bucket for Carrying Concrete

on the power-house work, the spring water was piped to several drinking fountains.

There being no suitable housing accommodations in the village of Grand Mere for the working force, a workmen's camp was built on the east side of the river. Fig. 10 shows a street in a section of this camp for the foreign workmen. About 40 of these bunk houses were built, and a system of discipline was put in force to keep the camps in sanitary condition, occupants of the camps who did not keep their houses clean or who did not use the sanitary closets provided for them, being fined.

For the foremen and English-speaking workmen, a boarding house was built for those without families and a row of neat cottages was erected which were rented to married men. Adjoining the boarding house was erected

Fig. 10. Workmen's Camp at Grand Mere Falls

a bath house with showers and tubs for the free use of all employees. A club house was also built and equipped with pool tables, cigar stand, reading room and a barber shop. A nominal charge of 50c. per month was made for all club privileges.

These various provisions were effective in attracting to and retaining on the work an efficient force of contented employees.

In the organization of the H. E. Talbott Co., by which this work has been carried forward, H. E. Talbott, Jr., is general manager, and has resided at Grand Mere in general charge of all operations.

The progress made on the work this season has been so rapid that the entire plant would probably have been substantially completed by Jan. 1. The sudden financial stringency due to the European war, however, has made necessary a temporary curtailment of work, and, therefore, the date of completion is uncertain.

Snow Removal by Melting with Artificial Heat

By S. Whinery*

The opinion is quite general among engineers and others that, while theoretically it should be possible to melt snow on the streets by artificial heat at a reasonable cost, the method is impracticable and uneconomical in actual practice. Such experiments as have been made seem to confirm this conclusion. But the thoughtful enquirer is likely to reason that where a process appears to be practicable and economical in theory, failure to secure satisfactory results in practice may be due to a lack of knowledge or skill in applying it, and that the whole subject may be worth further investigation. The fact that, in burning, 1 lb. of coal gives off sufficient heat to melt from 70 to 90 lb. of snow, looks attractive at first thought to one who is not familiar with the difficulties of converting heat into useful work.

Snow removal in our Northern cities is one of the important municipal problems that has not yet been satisfactorily solved, though it has attracted much attention and has been the subject of no little unintelligent inventive skill. Many schemes and devices for disposing of snow by melting have been proposed and a number of them tried, only to prove failures because the basic scientific principles involved and their practical application were unknown or disregarded by the inventors.

There is not much available literature on the subject, and it may be worth while to review the scientific and practical elements of the problem, which are not so obstruse and complicated as those who have not investigated them are likely to imagine. The purpose of this article is to do this briefly, using for illustration a project for melting snow by the application to it of water, taken from the fire-hydrants, heated to a temperature just below the boiling point in an ordinary steam boiler and applied to the snow on the street by means of a hose and nozzle.

Assume that a standard 60-hp. portable boiler is used; i.e., a boiler capable of evaporating 30 lb. of water per hp. per hr., from a feed-water temperature of 100° F. to steam at a gage pressure of 70 lb., equivalent to about $29\frac{1}{2}$ lb. from a feed-water temperature of 50° F. The quantity of water evaporated in an 8-hr. day would be $29.5 \times 60 \times 8 = 14{,}160$ lb. To convert 1 lb. of water into steam under the conditions named, requires, we know, the absorption of about 1165 B.t.u. and the quantity of heat necessary to so convert 14,160 lb. of water is

$$14{,}160 \times 1165 = 16{,}496{,}400 \text{ } B.t.u.$$

The quantity of heat required to melt 1 lb. of snow from a temperature of 20° F. is:

	B.t.u.
To raise the temperature to 32°	12
Heat absorbed in fusion	142
Total	154

*Consulting Engineer, 95 Liberty St., New York City.

If the snow weighs 8½ lb. per cu.ft., the net quantity of heat required to melt 1 cu.ft. of snow would be:

$$151 \times 8\tfrac{1}{2} = 1283 \text{ B.t.u.}$$

But a part of the heat contained in the hot water would be lost in passing through the discharge hose, and in its application to the snow. If we assume that only two-thirds of the heat leaving the boiler would be made actually available for melting snow then the gross quantity of heat necessary to melt 1 cu.ft. of snow would be 1925 B.t.u., and the 8-hr. product of heat from the boiler should melt:

$$\frac{16,496,400}{1925} = 8569 \text{ cu.ft.} = 317 \text{ cu.yd. of snow}$$

To heat 1 lb. of water from 50° F. (the assumed temperature of the hydrant water) up to a temperature of 210° requires 210° − 50° = 160 B.t.u., and since the boiler is capable of developing 16,496,400 B.t.u. per 8-hr. day, the quantity of water so heated would be:

$$\frac{16,496,400}{160} = 103,102 \text{ lb.} = 12,363 \text{ gal.}$$

What would be the cost?

We may safely estimate that in a portable locomotive-type boiler of 60 hp. capacity, 1 lb. of anthracite coal would evaporate 6 lb. of water, and as the evaporating capacity of the boiler is 14,160 lb. per 8-hr. day, the quantity of coal required would be:

$$\frac{14,160}{6} = 2360 \text{ lb.} = 1.18 \text{ tons}$$

The complete plant necessary would be the portable boiler equipped with a gasoline engine to propel it on the street, sufficient hose to connect the boiler to a fire-hydrant, and a short discharge hose and nozzle.

As the pressure would be that in the water mains only, a cheap second-hand boiler could be used, and condemned fire hose would answer the purpose. The cost of the plant would probably not exceed:

One second-hand 60-hp. portable boiler	$[illegible]
Hose, nozzle and connections	[illegible]
Gasoline engine attached to boiler truck	[illegible]
Total	$[illegible]
The yearly charges on the plant would be:	
Interest, depreciation and repairs, say 15%	[illegible]
Storage [illegible]	[illegible]
Total	[illegible]
If we assume that the plant would be used [illegible]	
[illegible]	[illegible]
The total operating expenses per day would be about:	
Plant expense	$[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
Total	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
Total per cu. yd.	[illegible]

The cost of hydrant water used is not charged in the estimate; in cities like New York, having an abundant gravity supply during the winter season this item may be neglected.

The above statements and figures seem to be conservative on the side of safety, and if so, the results ought to be attainable in practice. The figures seem sufficiently promising to warrant a fair trial of the project under working conditions.

We have in the above figured on melting all the snow on the street. It is probable, however, that more or less unmelted, or partly melted snow would be carried into the sewers with the current of water, thus tending to reduce the cost.

Recent experience in New York City seems to favor the method of disposing of snow by collecting and forcing it into the sewer-inlets and manholes by the use of a jet of cold hydrant water. By the hot-water method, no handling of the snow would be necessary. It would be melted as it lies on the street, and the resulting water would flow into the sewer inlets. There would probably be no question of the capacity of the sewers to handle all the water produced.

It is not intended to here discuss the probable merits or demerits of artificial snow melting, nor the practical difficulties and objections to be encountered. The purpose is only to outline the technical problems involved, for the use of practical men or inventors who may wish to give the matter further consideration.

The hot-water project was taken for illustration not only because it includes most of the technical elements involved, but because water is a good absorbent and conveyor of heat, and by its rapid penetration into the snow should transmit its heat to the snow with comparatively little loss. The plant used for illustration is crude, for it is to be remembered that in steam boilers only from 50 to 80% of the heat yielded by the fuel is actually taken up by the water. It is quite possible that a more efficient type of heater for the purpose could be devised.

At first thought, it would seem that a project for the application of the heat from the coal directly to the snow would be more economical and less complicated, but as this seems to involve the application of the heat to the surface only of the snow, the heat losses would be much greater than from the penetrating hot water.

Concrete Steps and Retaining Wall

A recent feature of park construction work at St. Louis is a long flight of steps on the slope of Government Hill, in Forest Park. It is about 115 ft. long, with a total rise of 35 ft., the steps being interrupted by two platforms. It was designed originally as a monolithic structure throughout, but Nelson Cunliff, Superintendent of Construction of the Park Department, thought that this would result in unsightly cracks and that continuous expansion and contraction movements might result in the entire structure shifting downhill.

The design was therefore modified by putting an expansion joint through each platform, and designing each section as a beam with three pier supports. This is shown by the longitudinal section in Fig. 1. The middle pier serves as anchor, so that expansion and contraction movements take place in both directions from it. There is no longitudinal joint, but the steps are divided into two sections by a central [illegible] space. The steps are of rather unusual shape, 19½-in. tread and only 4-in. rise, so that it will be easy to wheel baby carriages up and down the steps. Each step has a pitch of ½ in.

The reinforcement in the beam along each side of the steps consisted of four [illegible] longitudinal bars at the bottom, three [illegible] of these being bent up to come to the top of the beam at the piers, as shown in Fig. 2.

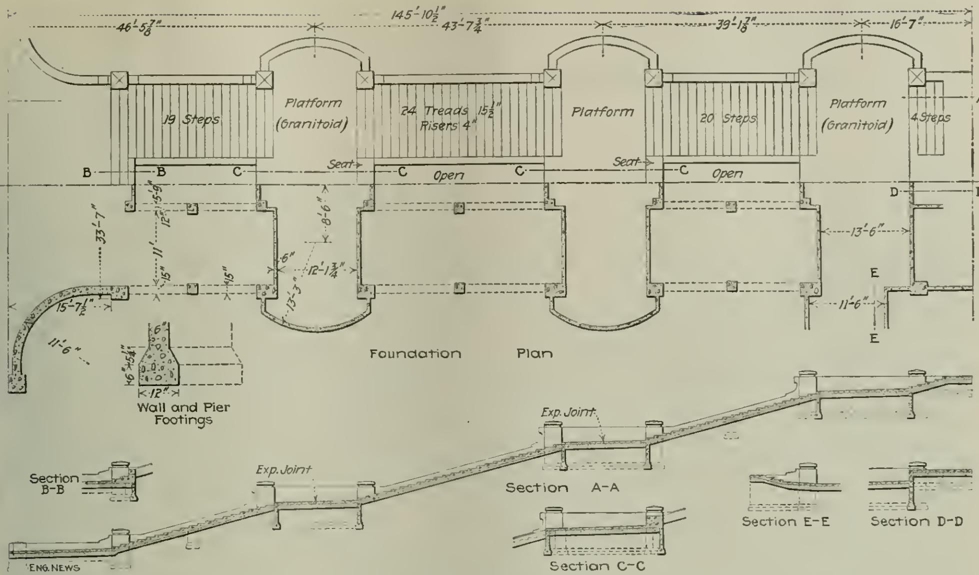

FIG. 1. PLAN AND CROSS-SECTION OF CONCRETE STAIRWAY ON THE SLOPE OF GOVERNMENT HILL IN FOREST PARK, ST. LOUIS, MO.

The structure is divided into sections by transverse expansion joints, and each section is anchored in position by a transverse pier at the middle.

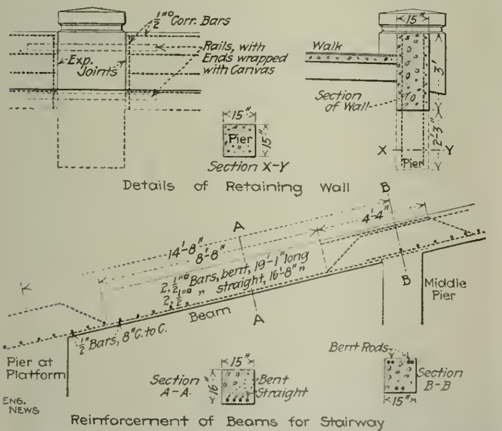

FIG. 2. DETAILS OF LOW RETAINING WALL AND THE REINFORCEMENT OF THE BEAMS OF THE STAIRWAY

Across the bottom bars were laid ½-in. transverse bars spaced 8 in. c. to c. Over the transverse bars were laid longitudinal bars 2 ft. c. to c. to prevent surface cracking. All bars were embedded at least 1 in. in the concrete.

The concrete is made with 1½-in. stone, the mixture being 1:2:4, and a granolithic surface is given to the steps. Wood forms were used. The construction was done by the park department force.

From the top platform of the flight of steps a concrete walk, at *E*, Fig. 1, will extend along the top of the slope of the hill in front of a pavilion. This will be supported by a retaining wall, which forms also a low parapet and has piers at intervals of 9 ft. 9 in. and 10 ft. 6 in. The wall is 13 in. thick and 3 ft. deep, or 5 ft. 3 in. deep at the piers. In front of the entrance to the building the walk is widened, and there the wall is made 5 ft. deep (7 ft. 3 in. at the piers). At each third pier (30 ft. c. to c.) the wall has an expansion joint on each side of the pier, made as shown in Fig. 2. In the pier are embedded old rails with the ends projecting to be built into the wall, these ends being wrapped with canvas to form a slip joint.

A Panama Canal Veteran Dredge Retired—The seagoing suction dredge "Culebra" has been retired from service, moored alongside the wharf at Paraiso, Panama, and dismantled. The retirement of the "Culebra" follows the practical completion of the work it is best suited to do, in the Pacific entrance and at the lake level. Its sister ship, the "Caribbean," now at work in the Atlantic entrance, will be able, it is thought, to handle the maintenance work of removing silt, in both entrances. The remainder of the heavy work in the Pacific entrance will be done by ladder, dipper and pipeline suction dredges. Construction work in the Atlantic entrance was completed in December, 1913, and subsequent work has been confined to the removal of silt.

The "Culebra" was built by the Maryland Steel Co., and sailed from its yards at Sparrows Point on Oct. 9, 1907, for Balboa, by way of the Strait of Magellan. The vessel arrived at Balboa on Dec. 28, and was placed in commission on Jan. 21, 1908. It worked in the Pacific entrance channel and in the slips alongside the wharves at the Pacific terminus until Jan. 20, 1914, when it was transferred to the Gatun Lake level and put at work removing gravel washed into the canal channel near Gamboa by the Chagres River. It was transferred to the dry dock at Mount Hope for overhauling early in June, and on June 14, was returned to Balboa, where it was engaged alongside the steel pier and in the entrance channel until the time of its retirement. The "Culebra's" output up to July 1, 1914, amounted to very nearly 19,000,000 cu.yd. The yearly output varied from 1,785,166 cu.yd. in 1912-'13, when it was out of commission 70 days, to 3,960,153 cu.yd. in 1908-'09, with 21 days out of commission. —"Canal Record," Sept. 2, 1914.

The Calaveras Dam, California, the Highest Earth Dam

By A. J. Cleary*

SYNOPSIS—The highest earth dam yet on record is the Necaxa No. 2 at Necaxa, Mexico, which has a finished height of 192 ft. The Calaveras Dam, now under construction, is to be 240 ft. high. It is to retain the waters of a new reservoir for the Spring Valley Water Co. of San Francisco.

San Francisco's rapid growth has created a demand for a more adequate water-supply. The construction of the Hetch Hetchy System, recently begun by the municipality, will require some eight years to complete. Meanwhile, the Spring Valley Water Co., which now supplies practically the entire city, is increasing its resources by the erection of the largest earth dam ever built. The completion of this structure will add to the company's system a reservoir with a storage capacity of 53,000 million gallons. This reservoir site is located in the wide level valley of Calaveras Creek, Alameda County, 30 miles southeast of San Francisco.

The watershed tributary to the reservoir extends southerly from the dam site for a distance of 25 miles, and has an area of 98.3 sq.mi. By the construction of a diverting dam on Upper Alameda Creek and a short tunnel through an intervening ridge, 33.3 sq.mi. additional may be included in the catchment area. The mountains that form the boundary of the drainage basin are precipitous, yielding a large percentage of the rainfall as available runoff. The elevation of the highest peak is 1200 and the lowest ground elevation in the reservoir is 560 ft. above sea level. The slopes of the entire watershed are partly thickly wooded, the ground elsewhere [illegible], except in the valley proper, fit only for grazing. There are few [illegible] in

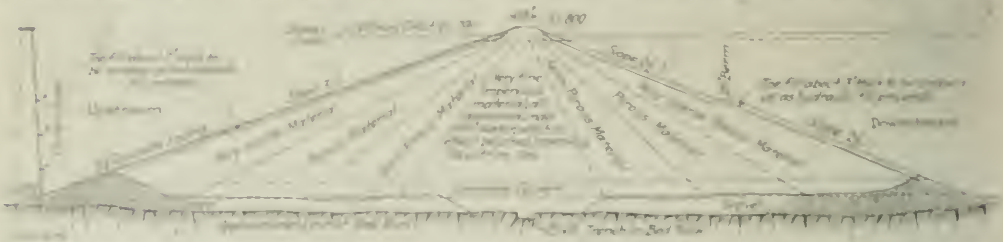

Fig. 1. Drainage of Calaveras Reservoir [illegible] San Francisco, Calif.

the drainage area not owned or controlled by the Spring Valley Water Co., and the water is thus insured from contamination.

Precipitation is principally in the form of rain, but occasionally snow [illegible] the upper reaches. This varies considerably from year to year, 27.7 in. being the normal seasonal rainfall for a period of 37 years. The maximum for one season was 47.1 in. or 70% above the normal, and the minimum 14.2 or about 51% of the normal.

After very extensive explorations, consisting of shafts, borings, tunnels and stripping over a considerable length of the outlet gorge of Calaveras Valley and the study of plans of various types of dam, the present site was finally chosen as the best for the type of dam it was decided to build, by reason of the quantity of material required, the location of borrow pits, and the position and character of bedrock. The type chosen was that of an earth dam with slope dimensions. The method of construction adopted was the hydraulic-fill method.

Design

Calaveras dam, as now being erected, will have a maximum height of 240 ft. above bedrock. In sectional thickness at the base it [illegible] ft., and at the top will be 25 ft., while the crest will be 1200 ft. in length. No core wall will be separately constructed, but great care is being taken in handling the sluicing material so that only fine, impervious clay will be deposited in the center, flanked on either side with porous material grading from sandy material next to the clay to heavy coarse gravel near the faces. On the upstream side the 3 to 1 slope will be

*Assistant City Engineer, San Francisco, Calif.

Fig. 2. Upstream View of Calaveras Dam Site, Showing Culvert to Be Afterward Covered

faced with concrete as a protection from scouring wave action. The downstream face will have a slope of $2\frac{1}{2}$ to 1, with a 20-ft. berm 100 ft. vertically below the crest.

A trapezoidal spillway of ample capacity will be constructed 10 ft. below the crest of the dam. Additional drainage is provided by means of a concrete culvert which rests on bedrock for its entire length beneath the dam. This has a 15-ft. drop between the toe and heel of the dam, and a net sectional area equivalent to a 20-ft. diameter circle.

Connected to the outlet culvert by a circular concrete tunnel is a reinforced-concrete gate tower of interesting design. It is founded on bedrock adjacent to the upstream end of the culvert, and will be 229 ft. in height above the rock foundation. The shell is 4 ft. thick at the base and 1 ft. at the top, with an inside diameter decreasing from 20 ft. to 10 ft. The concrete foundation is octagonal in shape, 50 ft. in diameter, 9 ft. thick and heavily reinforced. It is of the "open" type, with outlet pipe, gate valves and stairway on the interior. A sluice gate on the outside admits water to the valves. Being located in a district generally subject to seismic disturbances, the tower has been designed especially to withstand severe earthquake shock, and the assumptions and stress analysis are of much interest.

Fig. 3. Laying culvert.

Fig. 4. Turning Arch.

Figs. 3-4. Culvert under Construction

Construction

Like most Western streams, the Calaveras is of a torrential nature, varying from a few second-feet in summer to a raging torrent in winter and to provide for handling the waters of any floods that might occur while the dam was being erected, the 20-ft. culvert which will later contain the outlet pipes, was first constructed on the underlying bedrock. For this, a suitable foundation was prepared, with a $1\frac{1}{4}$-yd. steam shovel and hand work. Gravel for the concrete was conveyed by Fresno scrapers and a drag-line scraper from the gravel deposits in the creek channel 2000 ft. below the dam to an elevated platform. There it was washed down an inclined chute into hoppers, all silt and soluble material thus being removed. After the washing process, the aggregate in the bins below the hoppers was a clean mixture of graded sand and gravel, in which the voids averaged from 12 to 15%. From the bins, gravel was conveyed to three concrete mixers in 1-yd. cars. A 1 to 6 mixture was used throughout the structure, all joints being reinforced. A portable tower with elevator skip and hopper shown in Fig. [illegible], was used to place the concrete in part of the [illegible] of the culvert. In the central portion of the dam, five large concrete collars extending into the [illegible] and bedrock for a distance of about 10 ft. were built [illegible] the culvert. These are shown in Fig. 4. The purpose of these collars is to interrupt any tendency to seepage along the surface of the culvert.

Material to be incorporated into the dam is sluiced from borrow pits down an open channel having grades varying from 3% to 5%, to an 8x8-ft. concrete-lined sump. Two monitors similar to those used in placer mining, each having a discharge that can be fitted with nozzles varying in diameter from 1 to 5 in., loosen and wash the material from the borrow pits. These are operated at a discharge rate of 7 sec.-ft. with a nozzle pressure of from 80 lb. to 120 lb. per sq. in. (For very soft material a series of $2\frac{1}{2}$-in. hose jets are used instead of

Fig. 3. Giant Monitor Starting Material from Borrow Pit; Calaveras Dam

monitors.) The clay content of the aggregate at the borrow pit varies from 10% to 30%, with the remainder gravel and sand. In the open channel near the sump is a screen by which all boulders larger than 5 in. in diameter are removed. Water is supplied to the monitors by two [illegible] 10-in. pumps, operated at a speed of [illegible] r.p.m. by 200-hp. electric motors. The consistency of the mixture arriving at the sump is usually about 20% solids and 80% water. At the sump this is additionally diluted when necessary, an average of about 15% material in suspension being carried to the dam.

From the sump the mixture is raised to the dam by two 10-in. [illegible] pumps, which are driven by 300-hp. motors at such a speed that the velocity of the mixture in the

discharge pipes will be from 10 to 12 sec.-ft., according to the character of the sluiced material. It is essential to secure at least this velocity in order that no heavy gravel will deposit in the pipes. To insure a steady flow at this speed a booster pump is necessary when the material is being deposited at portions of the dam most remote from the sump. As the distance to borrow pits and the height of the dam increases, other booster pumps will be added. Slip-joint riveted-steel pipe, 14 in. in diameter, No. 16 gage, is used for the discharge line. To distribute the material properly and to raise the pipe line as the height of the dam increases, it is necessary frequently to disconnect and rejoin the pipe lengths. That the pipe may stand up under the ramming necessary with each change, a tip of No. 12 gage pipe 18 in. long was riveted to each end of each joint of pipe. This simple expedient has proved very satisfactory.

Fig. 6. Depositing Hydraulic Fill

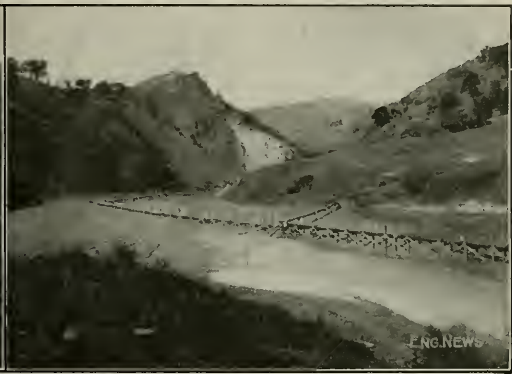

Fig. 7. The Sluiced Material in Place

Fig. 8. Collars on the Culvert under the Calaveras Dam

The sluiced material is discharged at the upper and lower faces of the dam and allowed to run on natural grades toward the center of the dam, where a pool of still water is constantly kept at the desired elevation. All porous material is deposited on the slopes approaching the pool, but only clay enters that portion of the dam covered by the central pool. By natural selection the porous material gradually changes from large rocks and boulders at the face of the dam to fine sand at the edge of the central pool. By regulating the elevation of the water in the pool the limits of the clay core are readily regulated. No water is wasted during the process, as the drainage from the center is conveyed through a 22-in. pipe back to the sump and thus used repeatedly.

Current for construction operations is supplied by the Pacific Gas & Electric Co. at 60,000 volts. This is transformed on the work to 2200 volts.

For the hydraulicking process fifteen men are required in each shift—one on each of the two monitors and one helper for both of these; three to operate the pumps; two to keep the 5-in. screens free from boulders; two to move the discharge pipes; one blacksmith; one electrician and three general helpers. Scraper teams are employed in smoothing the slopes of the dam and carrying up small levees along each face to divert the sluiced material toward the center of the dam. A steam shovel was used to excavate a central area 150 ft. wide to bedrock along the longitudinal center line of the dam. Directly under the crest line and through this central area, a cutoff trench has been excavated in bedrock. Over 3,000,000 cu. yd. of fill will be placed by the hydraulic process.

The concrete culvert to pass flood waters was taxed to its capacity on Jan. 1, 1914, 40 days after its completion. At this time Calaveras Creek changed from a small stream to a raging torrent, following a downpour of about 4 in. in 24 hr. over most of the tributary catchment area. Water rose in the pond above the dam to a height of 9 ft. above the roof of the entrance to the culvert, making it necessary to remove a short stretch of the culvert roof during the flood. It is estimated that 6000 sec.-ft. of water passed through the culvert for a period of 10 hr. By rapid work at the levee no damage was done by this flood. Subsequently several similar floods were passed through the culvert all without mishap.

All the construction is being done by day's work. The only contracts on the job are those for hauling material, supplies and equipment, and for boarding the men.

Design and construction of the dam are under the direction of F. C. Herrmann, Chief Engineer of the Spring Valley Water Co., and Wm. Mulholland, consulting engineer. T. W. Espy is Construction Engineer in direct charge of the work.

Contract Hydraulic Dredging for United States Government

In addition to the extensive dredging plant operated under the direction of the Engineer Dept., U. S. Army, a great amount of dredging is done by contract. The contract dredging for 1913 is shown in the accompanying tabulation compiled from the official report of the Chief of Engineers. As a rule, the major portion of this class of dredging is done in coast harbors along the Atlantic and Pacific Oceans and the Gulf of Mexico; an exception is the hydraulic dredging in the Saginaw River, Mich. The table is arranged by districts, alphabetically.

Dust Used Instead of Cement; Packed in Cement Bags—Defective concrete said to exist in a piece of public work in Los Angeles, Calif., is explained in a novel and [illegible] manner. What was thought to be cement was only dust! And this dust was packed in cement bags, came from a cement mill, and had been used accidentally, in good faith, by the contractors. A local newspaper gives the facts as follows:

Early yesterday the board of public works learned that the [illegible] with the concrete was caused by the accidental use of dust instead of cement in [illegible] the [illegible]. The [illegible] [illegible] that [illegible] [illegible] [illegible] the [illegible] [illegible] the [illegible] [illegible] the dust in [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] cement. This dust is used [illegible] [illegible] [illegible] [illegible] [illegible].

The board of public works accordingly [illegible] [illegible] that in future [illegible] [illegible] [illegible] [illegible] [illegible] for this purpose must be packed in sacks of a different appearance from those used for cement sacks.

Further news is to the effect that the board has ordered all cement and sand to be tested before use instead of afterward.

Editorials

Clams and Hope on the New Haven

In these times of business storm and stress, it is well worthy of record when one finds in a railway financial report a note of hope and optimism. Still more remarkable is it when such a thing is found in a report issued by the New Haven Co. It is surely of interest to repeat, therefore, from the report of the net corporate income of the New York, New Haven & Hartford R.R. for the month of July, just made public, the following twang of a cheerful lyre:

An interesting incident in New England commerce is the discovery of a very large deposit of clams between Martha's Vineyard and Nantucket. These are being moved in large quantities, principally to the New York markets, and the deposit appears to be large enough to insure a business for several years at least.

If the Stock Exchange were only open, this news ought to be worth a two-point rise in New Haven stock. If the retiring clam can aid in hoisting the New Haven out of the financial mire, and at the same time reduce the high cost of living in the metropolis by adding a durable article of diet to its food supply, the tale of its achievements may well be spread abroad. Perhaps some member of the talented literary staff who served under the former New Haven regime, writing "Prayers from the Hills" and other masterpieces, might celebrate the achievements of this gentle shellfish in lyric song.

The one disquieting note in the above quotation is the suggestion that this colony of clams is being treated like a mineral vein, and that in a few years is likely to be worked out. It is to be hoped that the compiler of this financial report has made some mistake and merely used the language to which he was accustomed in connection with copper, or iron, or coal mines in some previous railroad service. To exhaust a deposit of clams on the Rhode Island coast would be a calamity not lightly to be borne. Not even the financial exigencies of the New Haven Co. could justify such extremes of exploitation. The public will earnestly hope that so long as the New Haven Railroad continues to run, the deposits of Rhode Island clams will not be exhausted.

Injuries from Nails

To step on the point of a nail causes a direct loss of money. Somebody has to pay for the resulting injury, which is often a serious one. Unfortunately, the man who leaves the nail sticking up is seldom the one to step on it. But in the long run, if A steps on the nail that B left, and B steps on C's nail, C on A's, or otherwise around the circle of events, the situation is much the same as if every man that left a projecting nail point where somebody could step on it or catch on it was likely to suffer the injury himself. This is a clear argument for more care in dealing with projecting nails.

Two concerns state that injuries from nails form 3 to 6% of their total casualties, according to George Gilmore, Chief Engineer of the Travelers Insurance Co. "The Travelers' Standard" in an article on the nail hazard points out further that clinching a nail may make it more dangerous than the straight projecting point, if the clinching is not thorough. A nail point bent over so that it is nearly flat on the face of the board but yet clear of it a few sixteenths of an inch may catch the foot or hand to worse effect than an unclinched point, while at the same time it seems safe and thus invites the accident. The safe clinch shows the point is buried in the wood.

Under the workmen's compensation law now in force in many states, injuries to workmen from projecting nails may easily transform the profit on a contract into loss.

A Series of Papers on the New York Rapid Transit Railway Construction

We begin the publication in this issue of one of the most important and valuable contributions to engineering literature that Engineering News has ever had the pleasure of laying before its readers. We refer to the articles on the New York Rapid Transit Ry. extensions by Fred Lavis. Mr. Lavis' high reputation as an expert in connection with railway and tunnel construction is well known to many of our readers. He has made a special study of the New York subway construction in all its phases, and is to present the results of this study to the profession through our columns in a series of articles. Each of these will take up some special part of the work, so that each article will be complete in itself, and the entire series will make a complete technical account of the greatest piece of engineering work, figured by total expenditure, that has been undertaken in the world, almost without exception.

This series of papers will be of value not merely to engineers engaged in city rapid-transit subway construction in the future, for there is no doubt that other large cities will adopt this system of rapid transit to a great extent during the next quarter century. They will be of value also to engineers and contractors engaged in a great variety of construction work.

Take, for example, the underpinning of buildings affected by deep excavations, a class of work that has to be done at times in almost every city of the country. It is safe to say that nowhere in the world has building underpinning been carried out on such an enormous scale and under such difficult conditions as has been the case on the subway construction. The same thing may be said of deep tunneling under navigable rivers, of deep trenching through city streets, of provision for gas pipes and water mains, electric wires, and other underground street furniture in connection with large street excavations, of the transport of excavated material in crowded city streets, and of a number of other important primary operations in connection with the New York subway construction.

It must be remembered, moreover, that the engineering problems in connection with the New York Rapid Transit Ry. system, including the design of the completed

structure and the methods of construction, have been thoroughly studied by the largest staff of engineers, probably, that has ever been brought together in connection with any great public work. Speaking broadly, therefore, it may be fairly presumed that the New York rapid transit railway construction represents as good work as the engineering profession of the present day is capable of producing, while the methods adopted by the contractors on the various sections can safely be assumed to typify the best construction practice at the present day.

It may readily be understood that the difficult task of the author of these articles was to judge what to omit as well as what to include. The rigid limitations as to the space which could be spared in the crowded columns of ENGINEERING NEWS for the description of even so noted a work made it necessary to select only the features of greatest technical importance.

In describing a work of such magnitude, spread over such a wide area and involving so many features of difficulty and unusual practice at various points, it would have been easier to have made a description four times as voluminous as the present series of articles. The critical reader who follows these articles in detail will perceive that what has been presented in them are the technical facts of greatest interest and usefulness to the working engineer, while preserving enough of the general features to be interesting to the general reader.

A word of appreciation and acknowledgment is also proper here to the numerous members of the engineering staff of the Public Service Commission who have courteously aided Mr. Lavis in his work of collecting this information, as well as to the contractors and their engineers on the various sections, who have likewise extended to him much valuable aid.

Broken Rails and Derailment Accidents

In commenting on the causes of railway derailments in our issue of Aug. 13, we reviewed the statistics given in the accident bulletin of the Interstate Commerce Commission for the last quarter of 1913. It showed that only 128 derailments occurred in the three months on railways in the United States which were traced to broken rails. At this rate the total in a year would be 512.

A well known railway engineer, writing us to comment on these statistics, states that on his own road alone with about 1500 miles of track, about 500 broken rails occur per annum. There are, he estimates, judging from his own experience, at least 100 cases of broken rails to one derailment caused thereby. At this rate the actual number of rail breakages in a year for the mileage of the United States would be in the neighborhood of 45,000. Actually the number is likely three times as great.

The explanation of the seeming discrepancy is that the Interstate Commerce Commission's statistics of accidents include only those accidents which are reported to it, and its rules require the reporting only of accidents which either cause loss of life or serious injury, or which do damage to property exceeding a certain minimum amount. There are probably somewhere from three to four to a dozen derailments which cause no damage of consequence to every derailment which is serious.

Our correspondent makes the further point, however, that the deductions in the latter part of our editorial as to the general character of the rails now in service were not warranted. As to that, there may be two opinions. The statistics which we quoted certainly indicated that the danger from broken rails is not the appalling menace to the safety of railroad travel that might be supposed from some of the published matter on the subject of rail breakage. It is entirely true, on the other hand, that the great number of rail breakages in comparison with the derailments due to broken rails make statistics of the latter an unsafe basis for forming conclusions as to the character of the rails in service.

Inspecting Injured Bridges After Train Wrecks

An unusual bridge wreck on the Wabash R.R., at Attica, Ind., on Apr. 5 last, has just been reported upon by the Interstate Commerce Commission. As our readers will recall, this accident was described by Prof. Albert Smith of Purdue University, in our issue of Apr. 16. A derailed freight car struck the end post of a Pratt truss bridge, partially shattering it and bending it 6 in. out of line. It still had strength enough, however, so that the bridge stood up without collapsing. The engineer of the freight train pulled the front portion of the train to a siding and then came back, ran his locomotive onto the bridge, pushed the derailed car across it, and the car was then thrown down the bank to clear the tracks for a fast passenger train which had been held up. That train was then allowed to come over the bridge at a speed of not more than 3 or 4 miles an hour, and under its weight the bridge collapsed.

The technical features in connection with the stresses in the injured end post were reviewed in our issues of Apr. 16 and 23. The feature of chief interest in the Interstate Commerce Commission Inspector's report is the attempt to fix the responsibility for permitting trains to pass onto the bridge span in its dangerous condition.

It is clearly evident that none of the trainmen or trackmen at the site of the wreck had any idea that the injury to the bridge's end post, which was, of course, in plain sight to everyone, was a matter involving any serious danger. In fact, the whole matter of clearing up the freight wreck and moving cars and locomotives over the bridge was handled by the company train crew with the aid of a wrecking crew from Lafayette. The only man representing the Maintenance-of-Way Department, higher than a section foreman, was a track supervisor, who said frankly in his examination by the Inspector that he did not know much about such bridges and that he did not talk over the condition of the bridge with anyone except the section foreman. He said the bridge looked all right to him.

The only man who seemed to have any idea that the bridge had received serious injury and should have expert examination before trains were allowed to go upon it was the telegraph operator at the station nearest the bridge. He was, in fact, directed by the train dispatcher after the wreck occurred, to go to the bridge and see what damage had been done, and after inspecting he wired the dispatcher that the end post had been knocked out of line and that a bridge man should be summoned. The dispatcher consulted with the chief dispatcher, and they decided to have a bridge man go to the site of the wreck, but the only one they could secure was the track supervisor above referred to. The fatal mistake of relying

on the judgment of a track supervisor as to the safety of an important bridge structure under such conditions was very shortly demonstrated.

It is not to be expected, of course, that the ordinary train crew, or track foremen or supervisors would be competent to pass expert judgment upon the strength of an injured bridge. The important thing is that these men should not rely on their own judgment in cases of doubt.

The possibility of just such an accident as this on the Wabash exists on many another railway. It would seem well to add to the rules for trainmen and foremen of wrecking crews some rule reading somewhat as follows:

If any car or locomotive is derailed on a bridge or runs onto a bridge after derailment, examine the structure carefully, and if any parts of it other than the rails, ties, and guard timbers, have been struck and injured, report conditions fully to train dispatcher, who will notify Bridge Department and secure authorization therefrom before permitting any locomotive or car to cross the bridge.

The Responsibility for River and Harbor Appropriations

As briefly reported in our last week's issue, the U. S. Senate, on Sept. 22, passed the shortest river and harbor appropriation bill on record, and in doing so established a precedent which may possibly bring about a sweeping reform in the method of conducting our public works.

The bill simply provides a lump sum of $20,000,000 to be expended on the preservation and maintenance of river and harbor works already completed, and the prosecution of other river and harbor works already authorized by Congress. The entire responsibility for the expenditure of this appropriation and its distribution among the different works is placed upon the Corps of Engineers and their official head, the Secretary of War. In the apportionment of the money to various projects, the engineers are merely directed to favor those which are most desirable in the interest of commerce and navigation and which can be most economically and advantageously carried on.

It is seldom indeed that such sound common sense and businesslike procedure characterizes a piece of Congressional legislation. It is fair to say that the Senate passed this model river and harbor bill not by any means because of statesmanlike ambition to effect a reform in legislative procedure, but because the bill appeared to be a last resort if any appropriation for rivers and harbors was to be made at this session.

As already recorded in these columns, the bill as it was originally reported to the Senate from the Committee on Commerce carried appropriations of over $57,000,000 and was substantially the House Bill, with numerous changes and additions to suit the ideas of various Senators as to what should be provided for expenditure in the different States and districts.

The unanswerable criticism of this bill made by Senator Burton of Ohio, ably assisted by a number of other Senators, showed so fully the criminal wastefulness of the measure that the Senate eventually awoke to the fact that the enactment of the bill as originally reported would be political suicide. To revise the law, however, and include only meritorious appropriations meant that the amended measure would incur the hostility of every Senator whose pet appropriation was eliminated. The only way out of the difficulty, therefore, appeared to be for the Senate to abandon all responsibility for the apportionment of the money to the different localities and place that responsibility where in our opinion it properly belongs—with the engineer officers in charge of the work.

It still remains to be determined, of course, whether the House of Representatives will consent, like the Senate, to abrogate its powers heretofore exercised. That there will be violent protest against this is not to be doubted; but those who protest are likely to consider also that if they do not accept the Senate bill, there is little chance that any river and harbor appropriation bill of any sort can be passed at this session. There seems good ground for hoping, therefore, that the House will finally determine to accept the Senate bill with such grace as it may; and that the country may witness the remarkable spectacle of Congress providing a lump sum appropriation to be spent on public works, not for the purpose of enabling the Congressman from this or that or the other district to retain his seat in the House, but purely for the benefit of commerce and navigation.

It is understood, of course, that this handing over of responsibility by Congress is only temporary and also that it is not complete, since the responsibility of the engineers is confined to distributing the appropriation among the projects already authorized by Congress. Distinguished Senators and their colleagues in the House are, of course, firm in their intention to retain the say as to what new works shall be taken up; and they doubtless intend next year to resume their old plan of parcelling out the money for maintenance to each different item of work.

Notwithstanding this, a most important precedent has been established and it seems not too much to hope that in the light of this precedent public opinion may yet compel Congress to relinquish the responsibilities that do not properly belong to it at all and allow the public works of the country to be planned by experts with regard solely to their merits and usefulness.

It may be argued, of course, that the Corps of Engineers is fitted to pass on technical questions only and is incompetent to pass upon the complicated matters of commerce and economics involved in the decision as to whether or not a particular navigation improvement is worthy of being undertaken in view of its cost and its promise of commercial importance.

We may admit, for the sake of argument, that the Army Engineers are not infallible judges in these matters; but experience has demonstrated that Congress is not only still farther from the ideal in this respect but that as a matter of fact it does not attempt to judge. A large proportion of the projects to which it allots appropriations are only ostensibly for the benefit of navigation. Their real purpose is to secure the expenditure of money in a particular Congressional district. Surely the time is past when the waste of government funds in this way can be successfully defended. In fact, a large proportion of the Congressmen who take part in this annual pork-barrel distribution frankly condemn the system and accept it merely because it is a part of an established political custom which they deem themselves powerless to change.

It should not be overlooked, either, that this long established practice of distributing river and harbor appropriations among different Congressmen practically destroys the possibility of any intelligent systematic effort to improve our systems of inland navigation on a sound

and well considered engineering plan. It has been frequently pointed out to the public by the Inland Waterway Commission and other official bodies during the last few years that what is needed most of all in our river and harbor work is systematic and intelligent planning, so that the work may be concentrated where it will be of real public benefit instead of frittering away appropriations on unrelated projects and doling out the money for important works over such long periods of time that the whole scheme is obsolete before it is completed.

If Congress a dozen years ago, for example, had had the wisdom to place the entire work of navigation improvement in the hands of an able commission appointed by the President, made up largely of expert engineers of the highest standing and had provided for the use of that commission an annual sum no greater than has been expended on river and harbor works during that time, such a body would have been able to concentrate expenditures on works of real commercial value. By this time there might have been completed some of the large and important works that really promise enough benefit to navigation to be worth their cost.

And it is worth while, in connection with the above discussion, to point out that the principle involved is really far broader than the matter of river and harbor appropriations. There would be a vast improvement in legislative procedure and an immense public benefit if Congress would relinquish its long-established habit of framing appropriation bills to provide specific sums for each specific object, even going down so far as to fix the salaries of individual employees which the bill provides for. Such work does not belong at all to the legislative department of government. So far as Congress undertakes it, it does so to the neglect of other and far greater responsibilities.

Furthermore, this distribution of appropriations is actually not the voice of Congress at all, and often not even of the subcommittees of Congress, but is carried out by some clerical assistant to whose work a perfunctory approval is given. It would be vastly better to wipe out this absurdity altogether and provide in all cases lump-sum appropriations for general purposes, leaving to the executive officers in charge the apportionment and distribution of the appropriation in the manner which will be most to the public interest.

While the river and harbor bill which passed the Senate on Sept. 22 is a long step in this direction, it would be too much of an approach to millennial perfection to hope that any such principle will be carried into effect in the general conduct of our National legislation.

Letters to the Editor

Bridge Rerailing Frogs

Sir—I have noticed on p. 408 of your issue of Aug. 20, a reference to rerailing frogs, placed in the inner guard rails on the approach to a bridge, to eliminate danger by catching derailed wheels and guiding them back on the rails. Will you kindly inform me where I can obtain a sketch and description of this device?

F. GAMBLE, Chief Engineer,
Department of Railways, B. C.

Victoria, B. C., Canada, Sept. 2, 1914.

[Inquiry of a large number of frog and switch companies shows that five make or are prepared to make rerailing frogs. Three of these refer to the Childs-Latimer frog (the patents on which expired long ago); the Weir Frog Co., Cincinnati, Ohio, the Morden Frog & Crossing Works, Chicago, and the American Frog & Switch Co., Hamilton, Ohio. The Pennsylvania Steel Co. has made rerailing frogs to the designs of the Pittsburgh & Lake Erie R.R., and the Pettibone, Mulliken Co., of Chicago, has made them to the designs of the Morgan's Louisiana & Texas R.R. The Southern Pacific Ry. also has a design of its own.—Editor.]

Still More about Teredo-Proof Piles of Australian Woods

Sir—The letter in your issue of May 21, entitled "More about Teredo-proof Wood Piles," states that turpentine and ironbark are identical. Actually, they are far different both in appearance and strength.

Ironbark is practically never driven with the bark on while turpentine always is, and the bark is its protection. The latter timber is not very much used here as we have other borers which attack it. For temporary use, or in fenders, we often use swamp mahogany with bark on; but the regularly accepted pile (where not exposed to fretting) is ironbark (Eucalyptus creba by preference) sheathed with muntz metal.

Ironbark is one of the strongest and most durable timbers known. I have sample ties of it as sound as a bell after 45 years, and the average life of such a tie is at least 25 years.

W. PAGAN,
Recently Chief Engineer, Queensland Rys.

Brisbane, Australia.

On the Necessity (?) for Heavier Pavement Foundations

Sir—In ENGINEERING NEWS of July 23, 1914, p. 176, there appears an article on concrete foundations for pavements, in which the experience of the English engineers does not seem to be duplicated here.

In the operation of removing many thousand square yards of streets in New York I have had occasion to examine carefully the old concrete foundations. In many cases these were made with Rosendale (natural) cement. I have yet to see any evidence of crushing of the concrete foundation from excessive loads.

The foundations on some streets did not exceed 4 in., and averaged 6 in., and, while being removed, came up in large cakes 3 to 4 ft. wide, requiring several blows from

sledges to break the cakes. Cracks found in the concrete plainly seemed to be due to the settlement of the earth foundation, as the distance between the cracks was considerable.

Where cave-ins occur it is often found that the concrete foundation apparently had for some time been spanning a hole 3 to 4 ft. across and finally gave way when the span became too great. A cavity as large as 30x12 ft. has been discovered by a hole about a foot square finally being broken in by a truck. The concrete here was only 6 in., the usual thickness.

Much of the area paved with asphalt blocks in New York City has a foundation of only 4½ in. thick, as the ½-in. mortar bed cannot properly be considered concrete foundation. In the Borough of Manhattan the standard thickness of concrete foundation is now 6 in., increased occasionally where required over bad material.

Unless provision is to be made for spanning such large cavities as are mentioned above, it would appear that the present thickness of 6 in. of 1 : 3 : 6 concrete of the quality now being laid is quite sufficient.

R. A. MacGregor.

2428 Lorillard Pl., New York City, Sept. 8, 1914.

Need of a Home Export Manager for South American Trade

Sir—One important point is apparently overlooked in the present movement toward developing better American business relations and trade with the countries of South America—that is, the need of an Export Manager in the home office, who has been trained in those countries and appreciates their needs.

The obstacle that presents itself is that the United States is not prepared to meet the conditions and requirements of the South American trade. In fact, American firms, except a very few, know nothing about these requirements; but doggedly insist upon the foreign trade accepting what the American firms presume in their ignorance to offer them.

The fact has been that the representative, engineer, contractor or merchant of the South cannot obtain what he wants when he places his order in the United States. Cabled orders are not given due notice, and it is not uncommon after giving an explicit order for timed delivery, followed up by cables, to find on the ship on which the goods are expected, a letter proposing to send something different than ordered, under the excuse that the purchaser was ignorant of what he wanted, whereas in fact the ignorance was on the part of the American firm.

Troubles in packing and labeling are met in ordering steel, mill work and almost every constructive material, whereas orders to Europe will bring the article just as ordered without delay or question on the set time and with the advantages of low freight rates in European bottoms. The high American shipping rates in American colonies such as Porto Rico were partly offset by the former high tariff, but even there the Europeans met the American prices C. I. F. in spite of the American customs duty. This condition must be attributed to the ignorance on part of the Americans at home and the knowledge on the part of Europeans of the requirements of the South American trade. The manufacturers of the United States are just awakening to the necessity of adjusting themselves to the requirements of this trade.

The banking system is being extended by large banking houses, and there is no doubt but what the American banker will meet the demands as he sees the value of the business. The Canadian banks are there in full strength, have studied the requirements and are pushing themselves in wherever there is an opening.

The American steamship companies now have their opportunity while the war is on to get fully into the field. By the time that European ships come again into the field, the steamship companies may win a subsidy from the government; or if not, they can at least take advantage of the situation now and foreign bottoms can be used again after the war to carry American goods.

The manufacturers and supply people in the States, however, are complaining about the man in the field. They fail to see that they need an experienced Export Manager at home to understand the orders from the representative in the field and see that the orders are properly handled. The American representative resident in the foreign country soon learns to conform to the new condition by necessity; but his hands are tied if he is not understood in the home office.

American supply houses require Export Managers who have graduated through years of experience in the field. They should be drawn from men who have been trained in South American countries and probably have been promoted to Managers in their fields. The Export Manager at home should be the next step; but the supply house has failed to see the necessity of that important position.

Frederick O. Lewis.

Aug. 31, 1914.

NOTES AND QUERIES

Notes and Queries—"Subscriber" is informed that anonymous communications cannot receive attention from the editors.

Girard Point Elevator—The following corrections are to be noted in the article by S. H. Ingberg in "Engineering News," Sept. 17, 1914. On p. 573, fifth paragraph, is the statement "Each band is made up of two lengths lapping 3½ in." etc. This should read 3½ ft. In Section AA, Fig. 4, p. 575, the lower first floor should be 7 in. instead of the 4 in. shown.

The Code of Ethics of the American Society of Civil Engineers has been adopted by a letter ballot vote of 1997 to 107. This code of ethics was printed in "Engineering News" of Apr. 30, 1914, previous to its discussion at the annual convention of the Society at Baltimore, Md. It is reprinted below, together with the result of the canvass of ballots:

It shall be considered unprofessional and inconsistent with honorable and dignified bearing for any member of the American Society of Civil Engineers:

(1) To act for his clients in professional matters otherwise than as a faithful agent or trustee, or to accept any remuneration other than his stated charges for services rendered his clients.

(2) To attempt to injure falsely or maliciously, directly or indirectly, the professional reputation, prospects or business of another engineer.

(3) To attempt to supplant another engineer after definite steps have been taken toward his employment.

(4) To compete with another engineer for employment on the basis of professional charges, by reducing his usual charges and in this manner attempting to underbid after being informed of the charges named by another.

(5) To review the work of another engineer for the same client, except with the knowledge or consent of such engineer, or unless the connection of such engineer with the work has been terminated.

(6) To advertise in self-laudatory language, or in any other manner derogatory to the dignity of the profession.

Pavement Records to Determine an Economical Policy in Repairs and Reconstruction

The Bureau of Highways of Philadelphia, Penna., of which William H. Connell is Chief, has devised and put into operation a system of pavement records which is designed to furnish not only a complete history of each city block of street pavement, but the data upon which to determine the proper policy to pursue with regard to continuing repairs to a street, repaving it, or changing the kind of pavement for one more suitable to the prevailing conditions. In other words, the information contained on these cards can be used to determine the economical life of the existing pavement and the type of

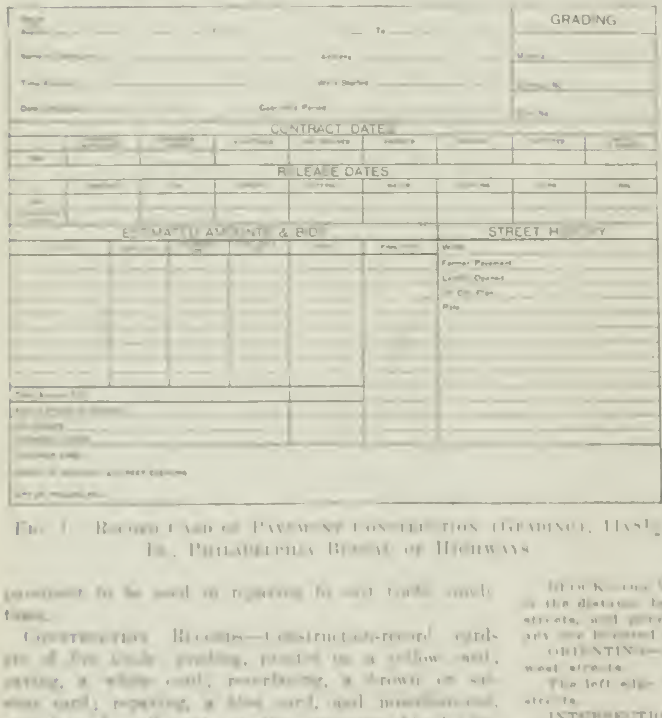

FIG. 1. RECORD CARD OF PAVEMENT CONSTRUCTION (GRADING), HASTINGS, PHILADELPHIA BUREAU OF HIGHWAYS

pavement to be used in repaving [illegible] traffic conditions.

CONSTRUCTION RECORDS—Construction-record cards are of five kinds: grading, printed on a yellow card; paving, a white card; resurfacing, a brown or salmon card; repaving, a blue card; and miscellaneous, a pink card. All cards are the same size, [illegible] in., and identically the same except in color and filing title. Fig. 1 shows the face of one of these cards, and Fig. 2 the reverse side of one.

It is readily seen by an examination of these reproductions, that [illegible] all the [illegible] information in regard to construction of the pavement [illegible] and [illegible]. The reverse of the cards, Fig. 2, shows the method of [illegible] the [illegible] plan, so that the progress of the work may be followed in the office. The record plan and following [illegible] are for [illegible] of [illegible] [illegible]. [illegible] to [illegible] these cards [illegible] [illegible] as cost data records, and [illegible] of the efficiency of the various contractors.

MAINTENANCE RECORDS—These cards [illegible] [illegible] the history of the [illegible] portion of each block and street intersection, together with the maintenance data of pavements laid since Jan. 1, 1912. The reverse side of each card is used for a stereotyped sketch of the block or street intersection, and, where practicable, shows the approximate location of each patch or section repaired. The cards for blocks of pavements are white, and for street intersections are green.

Many of the streets in the older portions of the city are narrow and are paved with asphalt on a broken-stone base. They are subjected to very heavy traffic which is concentrated largely on the shoulders, because of the street-railway track, and patching is done in the same places every year. Chestnut St. and Walnut St., between the Delaware and Schuylkill Rivers, are examples of this kind of street. The plotting of the patching done on these streets show that patching is in the same places each year, and brings out the high cost of maintenance required and serves as a powerful argument for replacing the old paving with a new one on a suitable base.

Another matter which these cards will control is the cost of restoration of the pavement over cuts made by plumbers and others having permission to open the streets. The data thus obtained will be used as a basis for obtaining equitable rates to be charged in cases of this kind.

The accompanying directions to engineers of the Bureau of Highways explain more fully the use of the street-maintenance record cards, which bid fair to become a most essential part of the Bureau's records.

DIRECTIONS FOR MAKING SKETCHES ON CARDS FOR HIGHWAY RECORDS

STREET—A street is a highway [illegible] for vehicular traffic, as defined in Street Cleaning Specifications, and the [illegible] will be found in the street-cleaning reports of the highway district [illegible].

BLOCK—One block will be shown on one card. One block is the distance between adjacent curb lines of the boundary streets, and generally includes the house numbers between [illegible] [illegible] numbers.

ORIENTING—The top of the card is north for all east and west streets.

The left edge of the card is north for all north and south streets.

INTERSECTIONS—Intersection cards [illegible] will be made out for all intersections of streets which are [illegible] [illegible] and for intersections of [illegible] streets which are [illegible] [illegible] boundary streets with block boundary streets and with [illegible]. The intersections of the small streets with the [illegible] streets and of the small streets with each other will not be shown on intersection cards.

BLOCK AREA—The block area will include the area [illegible] within the limits shown on the card, after deducting the areas of any intersections which may be shown on [illegible] other cards and any portion not paved. Generally the block area will be measured between the curb lines of the block and the adjacent [illegible] lines of the streets at each end of the block.

[illegible]—When a street is [illegible] to the property line at the intersections of streets which are not graded or paved, the [illegible] intersections outside of the curb lines shall be [illegible] to the block area.

[illegible] care must be exercised to avoid any duplication of [illegible] [illegible] or of the areas of the several kinds of paving [illegible] on the block [illegible].

[illegible] of the street [illegible] shown on the card which is [illegible] [illegible] or where for any other reason

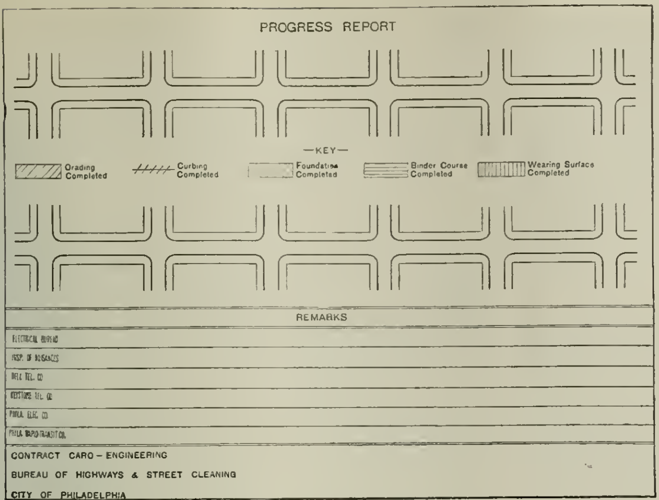

Fig. 2. Record Card of Pavement Construction (Paving, Reverse Side), 11x8½ In., Philadelphia, Bureau of Highways

is not to be included in the block area shall be plainly marked and with directions for reference if necessary.

Block areas will include areas comprised between the extensions of the curb lines and the radius corners.

LETTERING, ETC.—The name of the street and of the boundary streets shall be printed in CAPITALS. The remainder of the card above "Maintenance Data" on one side and above "Remarks" on the other shall be printed in script. As far as possible the space between the curbs shall be reserved for future entries and only street and curb widths and street grades shall be entered between curbs at this time, and such entries shall be made as small as possible. Grades shall be shown by the percentage of fall per foot, and the direction of the fall by an arrow point at the word "Grades." (Lengths of property lines between adjacent streets shall be noted on the footway opposite and in small figures.) The block length comprising the distance between the adjacent curb lines of the end streets shall be entered in its place below the lower property line.

If the block length of the upper side of the block is different from the lower block length, it shall be so entered above the upper property line. If both property lines are the same, the lower entry will be sufficient. All property lines and block lengths shall be to the nearest tenth of a foot. Street, curb and footway widths shall be entered according to the city survey plans.

INTERSECTING STREETS—All intersecting streets shall be drawn to scale, showing footways, roadways and radius of corner. The footway and roadway widths shall be entered at the right end of the card under "Remarks," one entry on each line, and shall be marked by letters, as "A," "B," etc., referring to similar code letters on the sketch

The space back of the house lines shall be kept for the future sketching of house and property lines. The space after "Square Yards" shall be kept free for the entry of the areas of the several pavements comprising the block area.

DIAGONAL STREETS—Owing to the difference of the longitudinal and transverse scales of these sketches, as printed on the cards, the direction of the diagonal streets will be shown by lines drawn through the corners of the property lines when plotted to the horizontal scale on the sketch. This applies to both intersecting streets and end streets.

ANGULAR AND CURVED STREETS—All angular, curved and other irregular streets and straight streets intersected by diagonal streets running in two or more different directions, shall be plotted on the special blank cards and to such scale as will best fill the card. The roadway and footway widths to be exaggerated as on the printed form when possible.

INTERSECTION CARDS—The highway intersection record cards (green) shall be filled out in the same manner as the highway block record cards. Special and irregular intersection cards will be used for all intersections which are not rectangular.

When plotting offset intersections where the line of one street is offset, the intersection will be located in the straight street opposite that portion of the offset street which divides the through street at the point where the numbering changes.

HOUSE AND PROPERTY LINES—House and property lines shall be plotted on the highway block cards so that the distance from the block corner to the nearest property line of the property so plotted, or the distance between the adjacent property lines of the properties so plotted shall not extend 100 ft. The frontage of the plotted properties and the distance of the property lines from block corners or from each other will not be plotted.

RECTANGULAR INTERSECTION CARDS—The upper edge of the highway intersection cards will be north; not true north, but the north used when plotting the streets between the intersections.

A Tar Macadam Pavement was laid on Margate Pier, London, England, as far back as 1820, or very shortly after the introduction of gas lighting. More than that, it was constructed by the "penetration method." This method of treatment was recommended for macadam roads by a correspondent of the "Mechanics' Magazine" in 1824.

Soil Loading Test for Foundation Design, Michigan Central Detroit Terminal

Difficult foundation conditions at the site of the Michigan Central Terminal, Detroit, in dense blue clay subsoil 100 ft. deep, led to extensive tests of piles and of direct soil footings. On the results of these tests was based the design of the remarkable reinforced-concrete mat footing already described*. While the tests were made 2½ years ago, their results have not been published. The

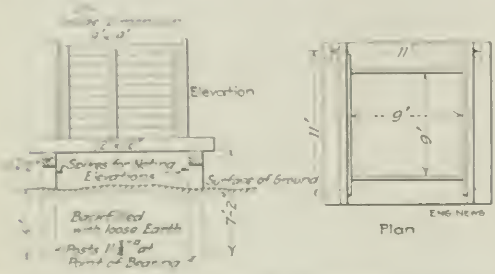

FIG. 1. TEST AND LOADING ARRANGEMENT FOR FOUR-POST SOIL TEST

following summary of the methods and results is abstracted from a copy of the official record.

FOUR-POST BOX TEST

Four vertical 12x12-in. posts, Fig. 1, were set in holes or narrow pits about 5 ft. deep, arranged in a square 11 ft. on a side. On the posts was built a platform supporting a square box. *The pits were backfilled with loose earth around the posts;* this evidently tended to maintain the original soil surcharge at the level of post bottom, and acted to prevent any direct squeezing out of the soil under the loading posts, such as might occur if there were a free surface nearby.

For the loading, the bin or box was filled with sand, carefully dumping the sand in the middle of the box and distributing it evenly to keep the load symmetrical. The posts were a little scant of 12 in. on a side, but the units of loading were adjusted to give integral values of load per square foot of bearing area.

COLD-WEATHER SETTLEMENT—Loading was begun Nov. 14, 1911, and continued until Jan. 25, 1912. Levels were taken daily to determine the settlements. The highest loading was 4 tons per sq.ft., which was reached Nov. 28, and remained unchanged from that date to the end of the test, two months.

The settlement of the posts during the period of increasing load was quite regular. Also during the following month, December, practically no movement took place under the 4-ton loading. But beginning with Jan. 2, 1912, in a time of zero weather, settlement recommenced and continued, with no letup, at a very uniform rate, until the end of the test period. The settlement during these three weeks was somewhat greater than the total settlement up to Jan. 2. The final settlement averaged 0.088 ft. for the two northerly posts and 0.059 ft. for the other two.

Evidently the load of 4 tons per sq.ft. exceeded the

*See "Engineering News," [illegible]

bearing power of the soil under particular conditions of moisture and temperature, or under variable conditions.

SINGLE-POST PLATFORM TEST

A second test, using a single-post platform, was carried to only two-thirds as high a loading, namely, 5500 lb. per sq.ft. Its special purpose was to verify the observations under low loadings. The post, 12x12 in., was set in a pit 5 ft. deep, backfilled with loose, dry dirt. Load was applied by I-beams and pieces of rail laid on top of the post, 2 ft. above ground level. Loading began Nov. 15, 1911, and the full load of 5500 lb. per sq.ft. was reached Dec. 15. The settlements were normal until after Jan. 2, 1912, at which time the settlement was about 0.02 ft. On Jan. 3, more rapid settlement began, and by Jan. 25, the end of the test period, the settlement had increased by 50%, to a total of 0.030 ft.

SILL TEST IN WELL

A third test was made in a well 19 ft. deep, on a bearing plate 2x2 ft., giving 4 sq.ft. bearing area. The well was *not backfilled.* The well and the arrangement for getting a measurement of the depression are sketched in Fig. 3. The load was run up to a maximum value of 6000 lb. per sq.ft. The test was begun practically at the same time as the preceding tests, but continued much longer, until Apr. 1, 1912, or 4½ months.

The load of 6000 lb. per sq.ft. was reached by Nov. 28, and the settlements up to this time and for four days following were normal. Between Dec. 2 and 4, a sudden settlement of 0.026 ft. occurred. There was no further settlement for 26 days. But beginning on Dec. 30, new settlement was noted, and as the curve in Fig. 3 shows, it increased steadily and rapidly, with no indication that the load came to a final bearing, even up to the end of the test on Apr. 1. The final settlement was

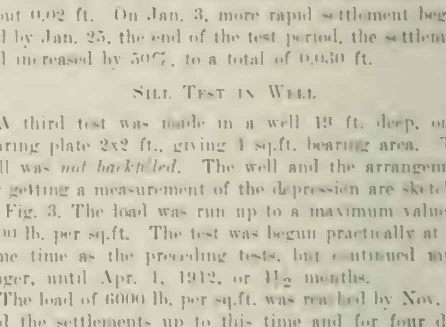

FIG. 2. SINGLE-POST TEST FOR CHECK ON EFFECT OF LOW LOADING

over 0.300 ft., and at this time the load was beginning to tip. This stopped the test in fact, as on Apr. 2 the load tipped against the wall of the well.

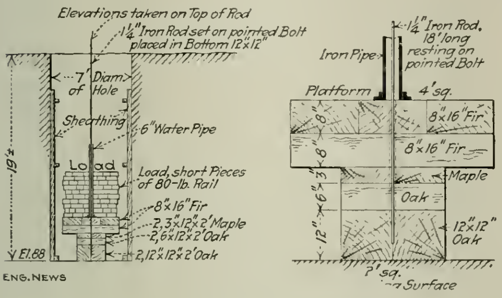
An important difference between the first two tests and the third (besides the absence of backfill in the latter) is that the former were open to the weather, while the well was covered by a wooden shed, and a drain trench was built around the well about 2 ft. distant to divert the surface water. In spite of this, the general phenomena of the settlement were the same as in the other tests. Water was not kept away from the loaded area

entirely, for at the end of the test there were 3 in. of water in the well.

The result of the test of the 2-ft. square sill in the well are shown in Fig. 3 by a curve, plotted on time as a base and settlements as downward ordinates. The temperature curve is plotted below, to show the influence of cold weather on the progress of this test.

Pier Test

A much larger bearing area and different conditions of loaded surface were tested by means of a pier test,



Test Arrangement for Sill Test

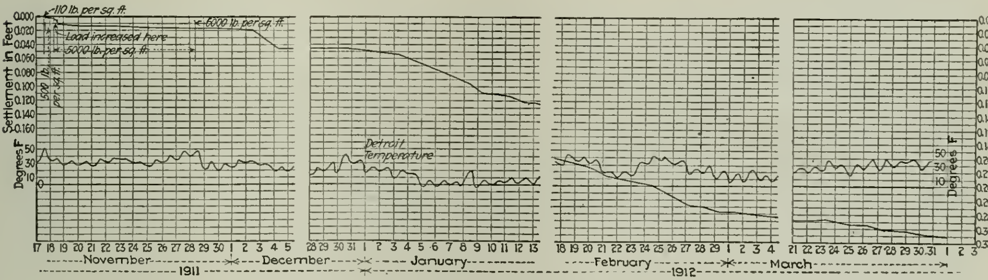
within the bearing capacity of the soil; whereas the preceding test showed that under somewhat different loading conditions a loading only 500 lb. higher exceeded the capacity of the soil and produced continuous settlement.

Use of the Data

It had been assumed in advance of the test that a load not greatly exceeding 2 tons per sq.ft. ought to be safe for the clay in question, and it was known that a satisfactory foundation could be designed within this loading. The results of the test were interpreted as confirming the belief that 2 tons per sq.ft. was safe.

Pile-Loading Tests

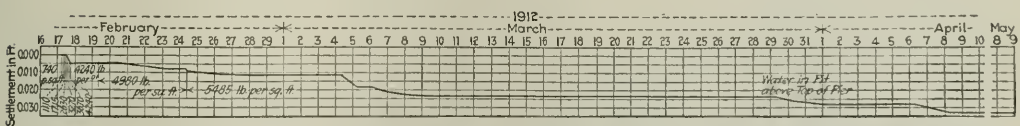
Simultaneous with the soil tests, test piles of various kinds were put down and loaded. In all, there were 36 such piles, comprising wooden piles and four kinds of concrete pile. At the start, it was decided that 20 tons safe loading per pile would probably justify the use of piles for the foundation. But the tests did not support the belief that 20 tons loading would be safe; on the contrary, all but two or three individual piles had what might be called their yield-point at or below 10 tons. On this showing, and the proof (by the soil-loading tests) that direct footings with 2 tons per sq.ft. would be safe, the direct footings were adopted; and, on the



Curves of Settlement and Temperature, for Sill Test

Fig. 3. Sill Test in Well

(Soil, blue clay just moist enough to be molded in the hand. Bottom of well carefully leveled. No indication of soil cracking or sliding in completed well; sheeting placed as precaution. Load, 1-ft. lengths of 80-lb. rail. Bottom of well, El. 88, Detroit datum.)



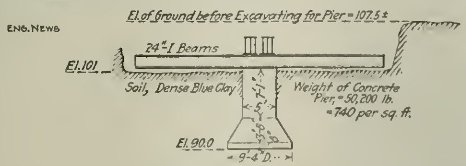


Fig. 4. Pier Test, and Settlement Curve

(Soil, dense blue clay.)

Fig. 4, begun in February, 1912, and continued until May. Here the loading was carried up to 5500 lb. per sq.ft., and while the settlement started and stopped somewhat irregularly at different times, the final result was a practically stable condition. It was concluded that this load, on a pier completely imbedded in the earth, was idea of Geo. H. Webb, Chief Engineer, and Olaf Hoff, called in consultation, the reinforced-concrete mat was used under the footings to equalize conditions.

The pile tests, also, showed very great variations between different piles, whether of the same or different types. No conclusions were drawn as to the advantage of one type over another.

Drainage Construction on United States Reclamation Service Projects to Dec. 31, 1913, had cost a total of $1,339,404 and it was estimated that by the close of 1914 the total outlay for this purpose would be about $2,500,000.

A Bridge Wrecked by a Derailed Passenger Train

A passenger train on the Baltimore & Ohio R.R. broke down a steel bridge at Woodlyn, Penn., near Philadelphia, on Saturday, Sept. 19, as was briefly noted in our last issue. This unusual accident is shown in the two views herewith, from photographs taken by the Philadelphia *Public Ledger*.

F. L. Stuart, Chief Engineer of the B. & O. System, describes the collapse of the bridge as being caused by damage to the end-post by the derailed train:

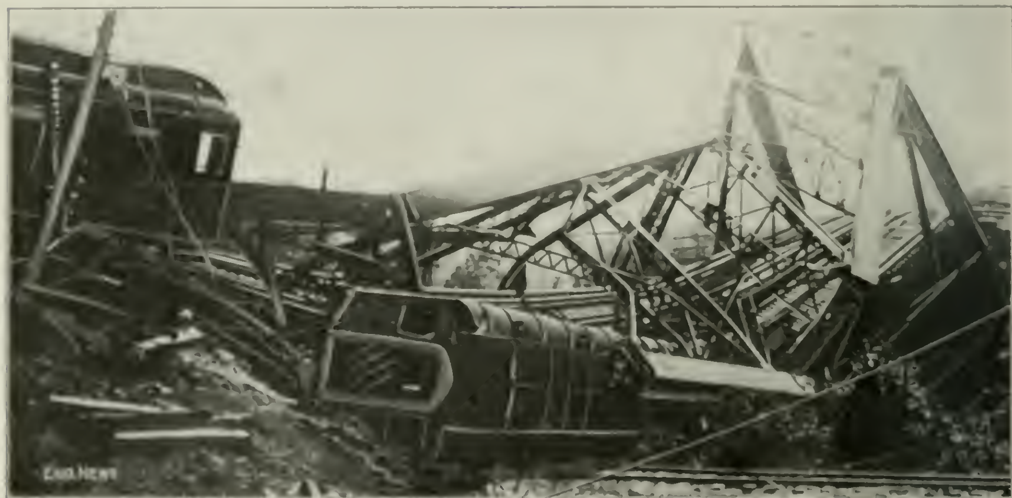
The train was westbound, and was derailed a few hundred feet east of the bridge, due to a broken axle in the forward truck of the tender on the north or right-hand side of the train. The engine and the first few cars passed over the structure, but apparently the first sleeping-car rammed the east end-post of the north truss, and damaged it to such an extent that the span collapsed in a gradual manner. After the wreck, the end-post was found broken in two.

Two of the floor-beam hangers and some of the other members of the structure were broken, but apparently the primary cause of the failure was the destruction of the end-post. There was no damage to the floor system proper which would have caused the collapse of the span.

The bridge is a double-track through span of Warren web with verticals; 163 ft. long c. to c. pins, six panels; trusses 34 ft. deep c. to c., and spaced $28\frac{1}{2}$ ft. apart. The floor has four stringers, i.e., two per track 7 ft. apart. The portals are open webbed trusswork; the remnants of the east portal may be seen indistinctly in Fig. 2.

Failure of Falsework under 12th Street Viaduct, St. Louis, Mo.

Later advices from St. Louis report that the partial failure of the 12th St. Viaduct noted on p. 661 of last week's issue, was not a collapse of the span during the removal of the forms, but a failure of some wooden falsework timbers during the laying of the concrete.



WRECK OF 163-FT. TRUSS BRIDGE BY A DERAILED TRAIN ON THE B. & O. R.R. AT WOODLYN, PENN.

(Both views are from the east end of the bridge. The right-hand or north end-post was broken, presumably by being struck by the first sleeping-car of the train.)

The 12th St. Viaduct consists of a number of deck-span units of reinforced concrete girder-and-slab construction, varying in span from 28 to 54 ft., which together make up a bridge structure 80 ft. wide and [illegible] ft. long, between abutments. The west half of spans 16 and 17, each [illegible] ft. long, and extending between expansion joints, were poured from each end simultaneously on Sept. 17. Span 16, the north span, extended over two through tracks of the Missouri & Pacific Ry., on which there is very heavy traffic. The newer por-

tion of the centering for both spans consisted of a 33-ft. span of old 24-in. 100-lb. steel I-beams, supported by 8-in. timber posts with 8x8-in. caps, and resting on grilled mud sills, the arrangement being such that two I-beams with two posts receive the weight of a concrete stringer and its slab portion. These posts were so braced that the ratio of slenderness amounted to about 15. They were intended to be proportioned for a load of from 800 to 1000 lb. per sq.in. A similar construction had been used successfully on all that part of the bridge which had already been built.

The pouring of the concrete was completed about 8 p.m., and the levels for the top of a coping along the west side of the bridge had been run, and the settlement was measured and found to be about 2 in. This coping is capped by a 3½-in. finishing surfacing, which is put on after the settlement has taken place. This was being put on at 8:20 p.m., when the centering collapsed under the west 20 ft. of the span 16—that is, the span over the railroad tracks—and the wet concrete fell to the tracks below, carrying five men, including the city's engineer and an inspector for the city, the superintendent for the contractor, and two concrete laborers. Two outside stringers, together with their slab portions, dropped the 30 ft. to the tracks below, leaving the inner three stringers and their slab portions in place. The men were more or less seriously injured, but are now recovering. The accident occurred immediately after the passage of a switching engine under the span.

The condition of the wreckage indicated that the failure of the wooden columns was probably the cardinal factor in the collapse. These posts should have been strong enough to take the loading, but some of them were spliced out of three pieces, and in addition possibly had insufficient lateral bracing. The accident may have been brought about by a variety of causes, such as the overloading of some of the posts by unequal settlement, the improper placing or fastening of slabs where some of the 8x8-in. posts were spliced, the unsymmetrical placing of the footings or sills for the posts with reference to the posts, the lack of square bearing on the spliced posts, etc.

A railway wrecking crew cleared up the débris in six hours. The cost of the accident to the contractor, including the removal of the débris and the reconstructing of the collapsed portion, will probably amount to about $2000.

※

A Temporary Bulkhead at Seabright—The citizens of Seabright have raised funds for the erection of a temporary bulkhead to replace in part the one demolished by the terrific ocean storms of Dec. 25-26 and Jan. 3-4. Jesse A. Howland is repairing the jetty in front of the Octagon Hotel property, and building a bulkhead 550 ft. long. Thomas J. Scully has a bill before Congress to build a breakwater at Seabright; but its passage is doubtful at the present time

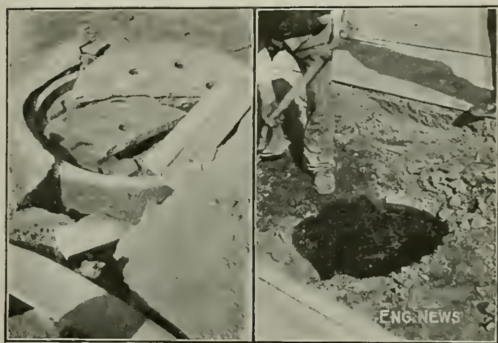
※

Studies of Mine Caving and Surface Support—Following the studies of mine-caving conditions and surface subsidence at Scranton, Penn., and the more general study of the mine-cave problem by the Pennsylvania State Anthracite Mine Cave Commission, further work will be done in this field by the U. S. Bureau of Mines in coöperation with the U. S. Geological Survey. Mining engineers and geologists of these two bureaus will make detailed studies of the extensive open-cut and underground mining operations of western New Mexico. Earth pressures and surface subsidence as related to geological formation and mining efficiency, and as affected by the mine equipment, will be studied. Charles Enzian, mining engineer, under the direction of Chief Mining Engineer George S. Rice, will represent the Bureau of Mines in the investigation.

Recent New York City Sewer Explosion

The accompanying views from photographs taken the morning following the sewer explosion in East 42nd St., New York City, described on p. 661 of Engineering News of Sept. 24, give some conception of the violence of the explosion.

Tests of the sewer air made in the same sewer subsequent to the explosion, by the Division of Combustibles of the New York City Fire Department, revealed very appreciable quantities of gasoline vapor. By search it was determined that certain garages were allowing considerable quantities of gasoline and oil to find a way into the sewer.



Manholes on New York Sewer after Explosion of Sept. 22

Notes from Engineering Schools

University of Pittsburgh—The School of Engineering will give evening graduate courses for men who hold a B. S. degree. This has been arranged to accommodate a large number of engineers in this district who desire to undertake further study but cannot devote any of the working hours to it. Courses will be offered in the mechanical, civil and electrical fields generally; among the special subjects are mentioned sanitation, concrete construction and railway mechanical work. Prominent engineers in the district will coöperate.

Ohio State University—A short course in industrial arts and science has been arranged for those who have been unable to take a regular technical course but who need preparation for advanced positions and added responsibilities. The studies will require two years, from about Sept. 15 to June 15. The entrance requirements are ability to read, write and compute; if an applicant is under 21 years of age, he should have had two years' practical experience in manufacturing. During the first year, the subjects covered are mathematics, drawing and shopwork; in the second year are given mathematics, drawing, mechanism, physics, materials, shopwork. Men proficient in any studies scheduled may substitute others.

A Department of Agricultural Engineering has been established. At first, instruction will largely be confined to building construction and management of machinery.

NEWS NOTES

Mt. Lassen's 18th Eruption Since May occurred on Sept. 21. [illegible] from the explosion which opened a new crater was felt at Macomber Flat, 3 mi. distant. The volcano now has four craters.

Heavy Blasts Brought down Plaster Ceilings in the Royal Victoria Hospital, Montreal, Que., recently. The hospital authorities have applied for an injunction restraining the contractors from blasting in the immediate vicinity of the institution. The work is in connection with the leveling of McGill campus. The ground was partly rock.

A Cylinder of Hydrochloric Acid Was Broken Open in the Jersey City station of the Erie R.R. and Hudson Tubes, during the rush hour, on the morning of Sept. 24. A steel-cylinder tank about 4 ft. long slipped and fell while being loaded on a car by employees of the Wells-Fargo Co., and the top of the tank was broken off. The accident occurred about 15 ft. from the stairways leading to the underground ticket office of the Hudson & Manhattan Tube Ry. The fumes were drawn into the long tunnel leading to the tracks of the Hudson Tubes. In 15 minutes, 25 persons had been overcome by the liberated gas, and many others were more or less affected.

A Break in a 48-In. Force Main at Cincinnati, Ohio, was noted in our issue of Sept. 24, 1914. At our request, J. A. Hiller, General Superintendent of Water-Works, Cincinnati, Ohio, has sent us the following note on the break:

The break was in a 48-in. pump main, wherein the pressure was about 185 lb. The break was about 4 ft. around the hub of the pipe, and extended about 10 ft. toward the spigot end. The pipe thickness was 2 in., was of even thickness throughout, and showed no flaw or defect. The main was laid in a stratified formation, and there was no settlement or movement of the pipe in any direction. The main has been subjected to the same pressure many times since its construction seven years ago. A check valve at the top of the hill closed, thus conserving the water in the tanks and in the mains above. This main was the only supply to a very large territory, and during the time repairs were being made a large number of people were without water. The break was repaired and pumping resumed in 44 hr.

A Partial Failure of the Stark Lyman Building in Cedar Rapids, Iowa, occurred in November last while the building was in process of construction. Full accounts of the failure were published in "Engineering News" at the time and it will be remembered that there was some controversy as to whether the failure was due to the designs on which the structure was erected or to the freezing weather that prevailed previous to the collapse while concrete was being placed. We are informed that the building has now been completed according to the original plans. Before undertaking to reconstruct the portion of the building which failed an official test was made of the standing part of the building which had been built before freezing weather, and the designs for the structure were submitted to several engineers [illegible]. On the approval of these engineers the reconstruction was carried out according to the original plans.

A City University for Cleveland, Ohio, is being studied by [illegible] [illegible] of the Cleveland [illegible] [illegible] The [illegible] the possible amalgamation of [illegible] University, Case School of Applied Science, and the Cleveland School of Art, as well as the city health, charity, welfare and [illegible] departments.

The Panama-Pacific Exposition Will Not Be Postponed, [illegible]

[illegible]

The Records for Placing Concrete Masonry [illegible]

of masonry of all kinds placed in the dam was 84,450 cu.yd., of this 1310 cu.yd. was placed by a second shift—deducting this the record for the month on a one-shift basis is as follows:

Number of working days (8 hr.)	$26\frac{1}{2}$ days
Total masonry placed in dam, all kinds	83140 cu.yd.
Average amount of masonry per day	3137 cu.yd.
Best day's work	3772 cu.yd.

The dam is now completed to Elev. 3[illegible] in one section, 314 in eight sections and 286 in seven sections. The top of the dam is Elev. 370. Seventy-six per cent. of the masonry is now completed.

This month's work will probably stand as the record on this structure, as the cross-section of the dam in the upper portions is so much smaller than below that it will not be possible to maintain the recent rate of progress.

During the five months, April to August, inclusive, 348,830 cu.yd. of masonry were placed in 128 working days, or a daily average of 2725 cu.yd.

An Exhibition of Street-Cleaning Appliances will be held in New York City, from Nov. 23 to 28, by the Department of Street Cleaning of New York City, according to a notice just sent out to manufacturers by Commissioner J. T. Fetherston (Municipal Building, Borough of Manhattan, New York City). The exhibit will be at Department Stable "A," 17th St. and Ave. C, Borough of Manhattan. Manufacturers and others are invited to show either working apparatus or models, illustrations of various sorts or other material. It is hoped that the exhibition will attract manufacturers and inventors from all over the country. Commissioner Fetherston's statement regarding the purpose, nature and object of the exhibit is as follows:

The purpose of this exhibition is threefold: (1) To show the people of the City of New York the types of equipment now in service. (2) To give manufacturers of modern street-cleaning apparatus an opportunity of exhibiting their various appliances, not only to the citizens of New York, but also to officials of surrounding communities who will be invited to attend. (3) To provide an opportunity for practical tests or demonstrations of street-cleaning appliances under such conditions as will be acceptable to the city and manufacturers.

The street-cleaning apparatus proposed for exhibition will cover all sorts of brooms, brushes, sweeping machines, flushing machines and other equipment or appliances used in cleaning streets and removing snow; garbage, ash and rubbish cans or receptacles used by householders; carts, wagons, motor trucks or other vehicles used for collecting garbage, ashes, rubbish and street sweepings; conveyances for transporting refuse by water or by rail; methods used for the disposal of garbage, ashes, rubbish and street sweepings, including garbage-reduction works, garbage crematories, incinerators, destructors, etc.

The City of New York is considering the adoption of improved methods and appliances for street cleaning, refuse storage, refuse collection and refuse disposal. An appropriation amounting to $1[illegible],000 has been made for the purchase of apparatus to be installed in a "Model District" of the Borough of Manhattan. The object of the exhibit will be to give every manufacturer or inventor an opportunity of bringing to the attention of the city officials their various appliances, likewise providing a chance for examining and testing these appliances during the period while the exhibit is being held. The city cannot guarantee expenses nor sales of apparatus, nor can it assume any responsibility further than the care of the equipment while stored at the city stable. All expenses and risks in connection with the exhibit must be borne by the exhibitors.

PERSONALS

Mr. S. L. Schoonmaker, of New York City, has been elected Chairman of the Board of Directors of the American Locomotive Co.

Mr. W. H. [illegible] has been appointed Assistant Engineer of the Chicago, Burlington & Quincy R.R., with office at St. Joseph, Mo., succeeding Mr. E. H. [illegible]

Mr. J. A. [illegible], of [illegible], Me., has been appointed County [illegible] and [illegible] County Highway Engineer of [illegible] County, Me., succeeding Mr. A. M. [illegible], who has resigned to engage in the contracting business.

Mr. Alfred C. [illegible], recently Architectural Engineer, Department of Buildings, Milwaukee, Wis., has been appointed Engineer of Construction of the new State [illegible] House buildings at North Milwaukee, Wis.

Mr. M. T. [illegible], Engineer with the [illegible] Railroad Commission, has been appointed [illegible] Inspector of [illegible] Division of Valuation, Interstate Commerce Commission, Southern District, with headquarters at Chattanooga, Tenn.

Mr. Thomas F. [illegible], a public school teacher of Long Island City, N. Y., has been appointed [illegible] Commissioner

of the Department of Water Supply, Gas and Electricity, for the Borough of Queens, New York City, at a salary of $4000 per annum.

Mr. Andrew W. Woodman, M. Am. Soc. C. E., Consulting Engineer, of Chicago, Ill., has been elected President of the Joliet Bridge & Iron Works, Joliet, Ill. Mr. Raymond Morrison has been elected Vice-President and Mr. Ernest Rollinson, Secretary.

Maj. C. O. Sherrill, Corps of Engineers, U. S. A., has been relieved of duty as Engineer in Charge of the Fourth District of the Mississippi River and the New Orleans Harbor improvement and will sail on Nov. 5 to take charge of fortification construction at Manila, P. I.

Mr. Augustus Griffin, Assoc. M. Am. Soc. C. E., Superintendent of Irrigation, U. S. Reclamation Service, Truckee-Carson Project, Fallon, Nev., has resigned to accept the position of Chief Engineer and Superintendent of the South San Joaquin Irrigation District, with offices at Manteca, Calif.

Mr. Alfred C. Callen, recently Assistant Manager and Draftsman of the Pottstown Machine Co., Pottstown, Penn., has been appointed Instructor in mining engineering at the University of Illinois. Mr. Callen is a graduate of Lehigh University, class of 1909, and was an instructor there until 1911.

Mr. A. H. Ayers, Assoc. M. Am. Soc. C. E., Superintendent of Construction, U. S. Reclamation Service, Great Falls, Mont., has been promoted to be Engineer on the Sun River Project at Fort Shaw, Mont. Mr. Ayers was formerly Division Engineer of the irrigation project of the Southern Alberta Land Co., Alberta, Canada.

Mr. Frank M. Patterson, for 27 years with the engineering department of the Chicago, Burlington & Qunicy R.R., has been appointed Field Engineer, Division of Valuation, Interstate Commerce Commission, Central district, with headquarters at Chicago, Ill. He was recently Engineer of the Missouri district of the C. B. & Q. R.R.

Mr. John Williams Davis, Assoc. Am. Inst. E. E., has been appointed Instructor in electrical engineering at the University of Illinois. Mr. Davis is a graduate in mechanical engineering of Cornell University, class of 1910, and has been an instructor in electrical engineering at Vanderbilt University and Leland Stanford, Jr., University.

Mr. F. R. Schanck, for several years in charge of the mechanical and engineering parts of the power and irrigation work on Indian Reservations for the United States Indian Service, has been promoted to be Assistant Chief Engineer of the Indian Service. He will have charge of the same branches of engineering, but his headquarters have been moved from Los Angeles, Calif., to Washington, D. C.

Mr. Horatio S. McDewell, Jr. Am. Soc. M. E., for the past year Assistant to Prof. L. S. Marks, of Harvard University, in his work as Editor-in-Chief of a new Mechanical Engineers' Handbook, has been appointed Instructor in mechanical engineering at the University of Illinois. Mr. McDewell is a mechanical engineering graduate of Harvard University, class of 1907. From 1908 to 1913 he was with the Allis-Chalmers Co., Milwaukee, Wis., first as an apprentice, and finally as Gas Engine Erecting Engineer.

Mr. F. L. Stuart, M. Am. Soc. C. E., Chief Engineer of the Baltimore & Ohio R.R., has been appointed by Mayor John Purroy Mitchel of New York City, a member of the advisory committee on port development at New York. Messrs. Ralph Peters, President of the Long Island R.R. and P. J. Flynn, Vice-President of the Delaware, Lackawanna & Western R. R., have also been named as members of the committee. The New York City Department of Docks and Ferries intends to work out a comprehensive plan for enlarging the shipping facilities of the harbor, and the coöperation of the large railway systems is sought.

Mr. Charles A. Ellis, Assoc. M. Am. Soc. C. E., former Resident Engineer, Dominion Bridge Co., Winnipeg, Man., has been appointed Assistant Professor of civil engineering at the University of Illinois. Prof. Ellis graduated from Wesleyan University, Middletown, Conn., in 1900. For a year he was Assistant City Engineer of Middletown, and for seven years Structural Engineer with the American Bridge Co. at Berlin, Conn., New York City and Ambridge, Penn. He was Assistant Professor of structural engineering at the University of Michigan from 1907 to 1912, and since then has been with the Dominion Bridge Co. of Canada.

Mr. H. C. Grant, former Superintendent of the Canadian Pacific Ry. at Brownville Jc., Maine, and recently Assistant General Superintendent of the Atlantic division at St. Johns, N. S., has been promoted to be General Superintendent of the Atlantic division, succeeding Mr. William Downie, who has retired after a service with Canadian Pacific Ry. extending over 27 years. Mr. Grout is a graduate of the engineering staff of the railway. He was in the construction and maintenance-of-way departments from 1898 to 1910, rising from the position of Rodman to that of Assistant Division Engineer at Toronto, Ont. Since 1910 he has been in the operating department.

Mr. Edwin Frank, Jr. Am. Soc. M. E., recently a draftsman in the centrifugal pump department of the Allis-Chalmers Co., Milwaukee, Wis., has been appointed Instructor in mechanical engineering at the University of Illinois. He graduated in mechanical engineering at the Massachusetts Institute of Technology in 1906, served a two years' apprenticeship with the Allis-Chalmers Co., Milwaukee, Wis., and then spent two years in Germany, where he was Draftsman and Engineer in the centrifugal, pump and steam departments of the Maffei-Schwartskopff Werke, of Berlin, at the same time attending the Konigliche Technische Hochschule zu Aachen. Since 1911 he has been with the centrifugal pump department of the Allis-Chalmers Co.

The Department of Architecture of the University of Illinois announces the following new appointments to the faculty: Mr. William D. Foster has been appointed Instructor in architectural design. He is a graduate of the Massachusetts Institute of Technology, class of 1911, and since June, 1913, has been Head Draftsman for Lour & Bollenbacher, Chicago, Ill. Mr. Ralph S. Fanning has been appointed Instructor in architectural design. He graduated from Cornell University in 1912 and for the past year has been a designer with F. J. Hughes & Co., Dayton, Ohio. Mr. William M. Stanton, a 1913 graduate of the University of Pennsylvania, has been appointed Instructor in architecture; and Mr. William S. Wolfe, a 1913 graduate of the University of Illinois, has been appointed Instructor in architectural engineering.

OBITUARY

Joseph F. Weekes, a retired Consulting Engineer, of Salem, Mass., died Sept. 20, aged 77 years.

John G. Haun, Supervisor of Bridges and Buildings of the Virginia & Southwestern Ry., of Bristol, Tenn., was killed, Sept. 14, when the motor car in which he was traveling was derailed in crossing a trestle.

John B. Carter, President of the Carter Construction Co. and the John B. Carter Co., New York City, died Sept. 10, at his home in that city, from nephritis. He is survived by a widow, a daughter and a son, John B. Carter, Jr. Mr. Carter was born Jan. 4, 1861, at Louisville, Ky. His father, Van Buren Carter, who was a newspaper man, died when the son was 18 months of age. His infancy was spent in Harrodsburg, Ky., where he received a common-school education. At the age of 15 years, he entered the employ of Tabler, Rosser & Co. as commissary clerk, and he remained with them several years. His next employment was with Mason, Hogue & Co., with whom he remained until he was 22 years of age, when he received a subcontract from that firm. His rise in the construction world was steady. It was a habit in his early career, which he followed to the time of his death, to remain personally upon any work which he undertook, or to be in constant touch with it. Some of his most noted achievements were the extension of the Bangor & Aroostook Ry., in Aroostook County, Maine; the construction of the Washington County R.R., along the east coast of Maine; an extensive system of government highways in Porto Rico; the construction of the Green Tree Tunnel and work for the Wabash R.R. entrance into Pittsburgh; the Indianapolis Southern R.R. from Indianapolis to Switz City, Ind.; the organization and construction of the Lake Erie & Pittsburgh Ry. from Cleveland to Ravenna, Ohio, which he sold to the New York Central and Pennsylvania systems; the Burlington extension from Herrin to Metropolis, Ill. The Western Maryland extension from Cumberland, Md., to Connellsville, Penn., will stand as an enduring monument to his genius and energy and capacity for the rapid accomplishment of gigantic undertakings, as this work involved the construction of 87 miles of very heavy work and included the removal of 6,000,000 cu.yd. of excavation, nearly all of which was rock; the construction of five tunnels and very heavy concrete masonry for bridges. The work necessitated the use of 47 steam shovels, and was completed in the record time of 15 months. Mr. Carter lived on this work, and the strain which resulted from the constant efforts to beat all previous records wrecked his health. Three weeks before his death he secured the contracts for the construction of the Mill Creek Joint District Sewer in St. Louis, at a price of $3,200,000. He left an estate in excess of $3,000,000 [Contributed by S. F. Cohen, Carter Construction Co.]

Henry Harbinson Sinclair, M. Am. Inst. E. E., whose death, on Sept. 1, was noted in these columns of Sept. 10, was a pioneer in long-distance electric power transmission. Mr. Sinclair was born in Brooklyn, N. Y., Dec. 22, 18[illegible]. He was educated in the public schools and academies of that city. When 1[illegible] years of age, he went to sea for three years, and in 18[illegible] entered Cornell University. Later he was engaged in the [illegible] business for several years in New York, following which he studied law at Columbia University. During [illegible] legal experience, his health failed, and he went to [illegible], Calif., in 1887, where he finally recovered. In 18[illegible], Mr. Sinclair, as one of the organizers of the Southern California Power Co., undertook the development of power in Santa Ana Cañon, near Redlands, and its transmission to Los Angeles, a distance of 83 miles, at 33,000 volts. The voltage and distance proposed were twice as great as in any long-distance line then existing or contemplated. Foremost electrical authorities refused indorsement, and thus his undertaking was heroic, both technically and financially. However, he succeeded in obtaining capital, and work was begun. During construction, the company's property was purchased by the Edison Electric Co., of Los Angeles, and the entire system (the largest hydro-electric project of its time) was made a success, under the management of Mr. Sinclair and superintendence of Mr. O. H. Ensign, now Chief Electrical Engineer of the U. S. Reclamation Service. During this period, under Mr. Sinclair's management, the Mill Creek Plant with 1960-ft. head, was built. This was for many years the highest head in the world. Under the active supervision of Mr. Sinclair, the Edison Electric Co. installed on its system the first oil-break switches, revolving field generators, 12,000-volt generators, high potential measuring instruments, steel towers and steam turbines ever brought west of Chicago. After the completion of the Kern River plant of the Edison Electric Co., Mr. Sinclair maintained a consulting engineering office in Los Angeles until 1909, when he went to San Francisco to assume management of the Great Western Power Co., which position he occupied for [illegible]. During that time the company carried on the construction of two monumental dams and developed an extensive power market. After severing his connection with Great Western Power Co., although because of failing health an [illegible] rest seemed imperative, his many interests in [illegible] and Lower California necessitated his maintaining an office in Los Angeles until 1911. During this time, under his management, the industrial city of Torrance was built, [illegible] another example of his wonderful executive ability.

Dec. 9-12. Convention at Richmond, Va. Secy., C. A. Prosser, 140 W. 42d St., New York City.

SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS.
Dec. 10-11. Annual meeting at New York City. Secy., D. H. Cox, 29 W. 39th St., New York City.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.
Dec. 2[illegible]-30. Annual meeting at Madison, Wis. Secy., F. M. White, Madison, Wis.

American Institute of Architects—The 1914 convention will be held in Washington, D. C., Dec. 2-4. The Secretary is D. Knickerbacker Boyd, Washington, D. C.

American Civic Association—The annual convention will be held in Washington, D. C., Dec. 2-4. The Secretary is Richard D. Watrous, 913 Union Trust Bldg., Washington, D. C.

National Society for the Promotion of Industrial Education—The annual convention will be held at Richmond, Va., Dec. 9-12. The Secretary is C. A. Prosser, 140 West 42d St., New York City.

American Society of Refrigerating Engineers—The annual meeting will be held in the Engineering Societies' Building, New York City, Nov. 30-Dec. 1. The Secretary is W. H. Ross, 1[illegible] Nassau St., New York City.

American Association for the Advancement of Science—The next convocation-week meeting will be held in Philadelphia, Penn., Dec. 28 to Jan. 2 under the presidency of Dr. Chas. Wm. Eliott. The Secretary is L. O. Howard, Smithsonian Institution, Washington, D. C.

Society of Naval Architects and Marine Engineers—The next annual meeting of the society will be held Dec. 10-11, at the Engineering Societies' Building, New York City. The usual banquet will be held at the Waldorf-Astoria on Dec. 11. The Secretary is D. H. Cox, 29 West 39th St., New York City.

National Conservation Congress—The secretary of the National Conservation Congress states that the 6th annual convention, which was to have been held at New Orleans, Nov. [illegible] will [illegible] on account of the war conditions [illegible]. The Secretary is Thomas R. [illegible], Washington, D. C.

American Public Health Association—In connection with the [illegible] annual meeting [illegible] Nov. 30 to Dec. 5, in Jacksonville, Fla., a [illegible] Health [illegible] will be held [illegible] Jacksonville, Fla. [illegible] will be [illegible].

Electric Vehicle Association of America—The program for the [illegible] annual convention has [illegible]. Among the items [illegible] are the following: [illegible] F. Walker; "Design and Performance of [illegible] Motors," [illegible]; "The [illegible]"; "[illegible] Development of the [illegible] Vehicle Industry," [illegible]; "The Motor Truck in [illegible]," [illegible]. The general office of the Association is at [illegible] West [illegible] St., New York City.

American Railway Bridge and Building Association—The [illegible] annual convention will be held in Los Angeles, Oct. 2[illegible] [illegible] with [illegible]. The following are the committees which will report and their chairmen: [illegible] C. E. Smith; [illegible] and Side [illegible]; [illegible] O. F. [illegible] M. [illegible] Cunningham; [illegible] Knowles; [illegible] F. L. [illegible]; Heating, Lighting and Ventilating [illegible] W. M. [illegible] G. E. [illegible]. The [illegible] will be held on Thursday evening, Oct. 22. The Secretary is [illegible] N. Waller St., Chicago, Ill.

VOLUME 72 OCTOBER 8, 1914 NUMBER 15

Building Bridge Substructures on the Grand Trunk Pacific Ry.

By W. C. Ruegnitz*

One of the most interesting features of construction on the Pacific Coast section of the new transcontinental line of the Grand Trunk Pacific Ry. is the bridge foundation work along the Fraser River between Tete Jaune Cache and Fort George, in British Columbia. For 185 miles between these points the railway follows the Fraser River through several ranges of mountains, the distance by river being 300 miles. The country is wild and rugged, and inhabited mainly by Indians and trappers.

In the summer the melting glaciers and snow turn the streams into deep, swift rivers, and because of the scour and swift current exceptionally good foundations are required. Temporary bridges could not be maintained over the larger and more dangerous rivers, and it was necessary to complete the substructures in advance of track in order to allow the quick erection of the superstructure when tracklaying reached the various bridge sites.

There are ten permanent bridges, from 2658 ft. in length to single-girder spans, and the three longest bridges cross the Fraser River. The substructure work of these bridges was commenced by some small individual contracts, but it was soon evident that it could not be carried on satisfactorily or with the necessary speed. In July, 1912, the contract for all the bridge substructure work from Tete Jaune Cache westward for some 450 miles or to within about 200 miles of Prince Rupert (the Pacific terminal) was awarded to the Bates & Rogers Construction Co., of Chicago. The writer was superintendent of construction for this company on the division between Tete Jaune Cache and Fort George, and work on this division was completed in May, 1914.

Fig. 1. Taking Construction Material and Supplies Down the Fraser River on Scows

Supplies and Camps

To complete the difficult foundations in the short time allotted and under the conditions described, necessitated very careful preparation. Markets for labor, plant and material were far away. Men were often shipped from Montreal and Boston, a trip of 10 to 14 days. Cement and steel from eastern Canada and Pennsylvania, requiring a lake and rail shipment, were often weeks in getting to destination. The base of supplies was at Tete Jaune Cache, at the end of the track. Here it was necessary to assemble all requirements to be freighted to the bridge sites.

The nature of the country was such that wagon roads were impossible, and the only means of delivering material was by boat or scow on the Fraser River, which is navigable only during the high-water period. Actual construction had to be carried on during the low-water period, which begins usually in October or November and

*Superintendent, Bates & Rogers Construction Co. (of Chicago), Prince George, B. C., Canada.

[illegible] until April or May. Thus the high-water period was a time of preparation. Camps had to be established quickly, and plant, supplies and material had to be transferred and stored at the various sites. The smaller details had to be carefully worked out in advance, as [illegible] would be without freight communication during [illegible] of the construction period.

[illegible] telephone system serving all the camps provided a wonderful help, although the line was not as good as the ordinary party line of the rural settlements. Most of the camps were located in heavily wooded districts, and fuel for all uses was cut during the summer months. Foundation piling and round timbers for construction purposes were cut in the fall and delivered to the sites

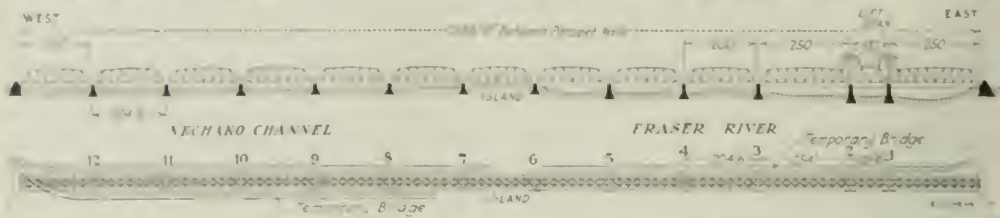

FIG. 2. BRIDGE AT THE FOURTH CROSSING OF THE FRASER RIVER, GRAND TRUNK PACIFIC RY.

[illegible] steamers of the usual river type were built to handle the freight but they could not begin to deliver all the enormous tonnage. Hence hundreds of scows 36 to 40 ft. long, 12 to 14 ft. wide, and carrying 12 to 25 tons each were floated to the jobs. They were handled by sweeps at both ends, each sweep being manned by two men. In the more dangerous cañons and rapids, pilots and extra men were put on to assist the regular crews, but even with this protection entire cargoes were frequently lost. The average mileage per day for a scow was 50 miles, while one would frequently make 70 miles. Their progress was augmented by the swift currents and the long summer days of the North. Fig. 1 shows the character of this transportation.

Nearly all cement was delivered by scows that were from 5 to 10 days on the way. False bottoms, covered with straw to absorb the moisture, served as a floor to [illegible] the cement. The sides and [illegible] of the barge were also protected [illegible] while the top was covered with a heavy [illegible] Rise boards were provided to protect the cargo from the [illegible] the river. [illegible] the cement [illegible] on the job it was [illegible].

The camps presented exceptional requirements. Ample storage room was necessary to accommodate the material and supplies that had to be delivered in advance of construction. Preparation for the long cold winter had to be made, and bunkhouses of logs well "banked" were used when lumber could not be easily procured. Sanitary conditions had to meet the requirements of the British Columbia Government. During the fall, when it was impossible to deliver fresh meat from the [illegible] supplies, [illegible] the [illegible] construction with [illegible].

When navigation was closed, the only means of [illegible] the camps was by [illegible]. [illegible] During the winter months dog teams [illegible] and sleighs [illegible] when the ice permitted. A

by water before ice closed the river. Square timbers were hewed on the job, there being many expert broad-axe men available.

SUBSTRUCTURE OF THE FRASER RIVER BRIDGE

All the bridges presented special difficulties but the largest and most interesting is that at Fourth Crossing, one mile east of the old Hudson's Bay Co. Post known as Fort George. It is just below the confluence of the Fraser and Nechaco Rivers. Here the line crosses an island, with the deep-water channel, known as the Fraser, on the east side, while the Nechaco, an overflow channel during high water, is on the west side. The length of the bridge is 2658 ft. As shown in Fig. 2, there are ten spans of 200 ft. and two of 250 ft., one at either end of the 100-ft. lift span. The base-of-rail elevation at pier No. 1 is 1867 above sea level, and the elevation of the river bed

FIG. 3. STAGES OF WORK ON THE PIERS FOR THE FOURTH CROSSING BRIDGE, FRASER RIVER

[illegible] 1871. High-water level is assumed as 1838 and the low water as 1822.

The west [illegible] of the island was selected by the contractors for their camp, accommodating 400 men. This was [illegible] purposes. The buildings were frame

buildings covered with prepared roofing. The storehouses for cement and material were large frame buildings covered with heavy oiled tarpaulins or "tarps," an exceptionally fine canvas made in Scotland. Tarps that had protected the cement on the river trip were used to cover the buildings. An auxiliary camp to accommodate 100 men was established on the east bank, on account of the great danger in taking laborers across the main channel during the ice floes before the contractors temporary bridge was completed. This proved very fortunate, for in the spring, when the ice took out all temporary structures, the work on the east bank was carried on without interruption.

A complete day and night organization was maintained for the entire work, each pier having a complete plant layout as well as an individual crew. A night and day foreman for each pier worked together, shifting their crews every two weeks. Each foreman reported to the general foreman, there being one general foreman for each shift. The general foremen reported to the superintendent in charge, who was located on the work. Fig. 3 shows the condition of work in December, 1913, and April, 1914.

Construction Work

The substructure consists of 12 concrete piers and two abutments, all resting on pile foundations, as shown. The deepest foundations are at piers Nos. 1 and 2, which were carried 25 ft. below low water, requiring 40-ft. steel sheeting. An ice jam which raised the water several feet above the top of the sheeting delayed all operations for several days. Careful soundings were taken before the work was started and showed a gravel bed with an underlying strata of very stiff sandy clay with layers of quicksand. The depth of gravel varied at different pier sites.

An exhaustive study of the individual pier and abutment sites was made by the contractors, and coffer-dams were designed both as to kind and strength to suit the local conditions. Three types of coffer-dams were used; crib, steel sheeting and a single row of Wakefield wood sheeting. The size of coffer-dams was designed to allow ample room for the necessary coffer-dam piles, bracing and timbers. The braces were spaced in order to allow of dredging with grab buckets and to permit the placing of pumping equipment.

Actual work on the shore was commenced in September, 1913, on the east abutment and pier No. 6, the only units then accessible. The temporary bridge from which all work was directed was started at this time and carried out as far as navigation laws permitted. Later, when floating ice stopped navigation, it was found a very difficult task to drive the remainder of the bridge and it was not until January that it was entirely completed. The river, with a current of 4½ to 5 m.p.h. and filled with ice, presented a formidable obstacle not only against the temporary bridge but it seriously hindered the placing of the coffer-dams.

The general program of construction for each pier was as follows:

1. Open dredging was carried down as far as possible.

2. The coffer-dams were then built. The crib coffer-dams were built and sunk in the ordinary way. For the steel coffer-dams, wood piles spaced about 8 ft. c. to c. were driven around the space to be inclosed; these were carefully lined up and two sets of timbers 4 ft. apart bolted on the inside piles (above the water) to act as guides for the steel sheeting. In Fig. 4 is shown a complete set of the steel sheeting in place and ready to be driven. Three or four complete sets of waling and bracing were then sunk into position and set as deep as possible. The steel sheeting was then set inside the guide timbers and around the waling, care being taken to get a locked dam. After closure the steel was driven the full depth required, usually 6 ft. below the elevation required for the bottom of the foundation.

3. Excavation inside the coffer-dam was continued with dredges (Fig. 5), teeth being used on clam-shell buckets when clay was encountered. The waling and bracing was sunk as the excavation proceeded. The excavation was usually carried 1 to 2 ft. below the bottom

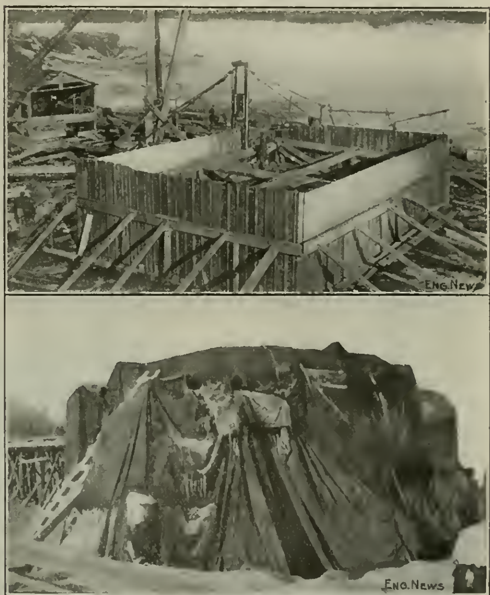

Fig. 4. Substructure Work on the Fourth Crossing Bridge

(Top view, steel sheeting for coffer-dam erected in place and ready to be driven. Bottom view, completed form and concrete pier incased with canvas, inside of which are steam pipes. (Temperature, 50° below zero.)

elevation required, in order to allow for swell caused by driving the foundation piles.

4. When excavation was completed, the foundation piles were driven and cut off under water at the elevation required by means of a saw (Fig. 5). The penetration of this piling usually averaged over 20 ft. below cutoff. The driving was very hard.

5. Concrete was then placed under water by means of bottom-dump buckets, using a 1 : 2 : 4 mixture. The amount of sealing used was carefully figured to prevent floating or "blow-in." The sealing was allowed to set from two to six days, depending upon the depth of water and temperature.

6. When the concrete was properly set the coffer-dam was pumped out. As the water was lowered, the bracing was examined and strengthened or repaired if necessary.

EXAMPLE OF CONTRACTOR'S WEEKLY PROGRESS REPORT ON BRIDGE SUBSTRUCTURE WORK
FRASER RIVER BRIDGE

The results in all cases showed exceptionally good ma[illegible]

(7) Forms were built (Fig. 3) and the pier concreted, using 1:3:5 mixture. The necessary precautions being taken (as described later) to protect it against [illegible]

CONCRETE WORK

For the Fraser [illegible], two concrete plants were used, one on the island and one on the east bank. Gravel was [illegible] at each pier; the only material to be loaded being cement.

To prevent freezing, the gravel was heated as mentioned above. Water was also heated, the mixed concrete coming to the forms very warm. The forms were entirely covered by heavy oiled canvas tarps, these extending from the top of the coffer-dams to the top of the forms, completely enclosing the pier, as shown in Fig. 3. Between the forms and canvas covering, fires were kept in small stoves, or steam heat was furnished in radiators built on

FIG. 3. WORK ON THE PIERS OF THE FRASER CROSSING BRIDGE, FRASER RIVER; GRAND TRUNK PACIFIC RY.

[illegible]

[illegible]

[illegible]

The forms had to be well built and braced with more than ordinary care before placing concrete, because the canvas covering did not leave an opportunity to examine the forms to determine if they were being kept in line.

Progress Records

The weekly progress report used by the contractor was a white print 28 in. long showing an elevation and plan of the bridge (on which the concrete progress was marked) and a profile of the river bed on which the progress of cotfer-dams and pile foundations was marked. On the print was a table for the excavation, cotfer-dam, piling and concrete at each pier, the table being filled in each week. The accompanying table gives one of these weekly reports of work of the main channel of the Fraser River for the Fourth Crossing bridge, shown in Fig. 2. In addition to this, a monthly report was made for each pier or abutment, showing the progress, materials used, etc., and the condition of the work. These graphic reports were made up at the superintendent's office and forwarded to the main office of the contractors, in Chicago.

Concrete Retaining-Wall for Flood Protection at Schenectady

A low concrete retaining-wall more than a mile in length was completed Sept. 1 by the General Electric Co., at Schenectady, N. Y., to protect its works from freshets in the Mohawk River. The property of the company is located a few hundred feet south of this winding river and adjacent bottom lands. Between the river road upon which the plant buildings front and the river channels, is the Erie Canal.

Previous to the spring of 1914, the banks of the canal prevented overflow into the works. The towpath of the canal is 6 ft. higher than the floor level of the works and permits a rise of 23 ft. of the Mohawk River before water can overflow the top of the canal and flood the plant.

This stage was exceeded in March, 1914, when the towpath of the Erie Canal was overflowed, closing navigation. Fortunately, at this juncture the ice gorges in the river broke, preventing a general inundation of the works. Water overflowed many of the principal streets in the lower sections of Schenectady, to a depth of 2 to 5 ft. The normal flow of the river in this vicinity is from 5000 to 7000 cu.ft. per sec.; but in the spring of 1913, reached 105,000 to 110,000 sec.-ft.

*Information furnished by General Electric Co.

Utilizing the Mohawk River for the Barge Canal made it necessary to create a pool 11 miles long with a dam 30 ft. high at Visschers Ferry, 3 mi. below Schenectady. This raised the general water level about 2 ft., which accounts largely for the high stage this year. Engineers of the General Electric Co., last January investigated the situation and recommended raising the present heelpath masonry walls of the Erie Canal about 3 ft. and increasing the height of the old dike extending around the southwest end of the company's property.

Work started on July 13 and was completed in six weeks by a gang of 25 men. The new flood-protection wall extends west from the Washington Ave. bridge to the earth dike. It is 5400 ft. long and about 2 ft. 6 in. high. It is 24 in. thick at the base and 14 in. at the top. It is dovetailed to the rubble-concrete canal wall. Thirty tie-rods of $1\frac{1}{4}$-in. steel 24 ft. long embedded in concrete and anchored to concrete deadmen, backbrace the heelpath wall to the embankment, where the old wall was out of plumb. Blaw steel forms were employed and all material was transported and mixed on scows. The wall contains more than 1000 cu.yd. of concrete.

A short section of the wall 225 ft. long will be run on the heelpath of the canal, starting just east of the Washington Ave. bridge and extending to a point where it can be directed across along the side of the illuminating laboratory, onto and abutting the New York Central railway embankment.

The work was done under the direction of Carl G. Hulth, Engineer and Superintendent of Grounds and Buildings for the company, and Chas. H. Benedict, Assistant Superintendent for the Eastern Division of the State Department of Public Works.

A Highway Crossing Signal now in use on the Lehigh Valley R.R. and other lines comprises a disk, lamp and gong in its indications. The signal is of the banjo type, with circular box mounted on a post as in an old form of automatic block signal. The signal is held at the "clear" position by magnetic attraction, but when the control circuit is broken by the approach of a train the magnet coils are demagnetized and the mechanism goes to the "stop" position by gravity, showing a large red disk at the larger opening in the box and bringing a red glass opposite the lamp opening. The gong is housed at the lower end of the banjo box. One design of the signal shows indications in both directions, so that only one signal is required for the crossing. This crossing signal is a development of the old Hall automatic block type.

Low Concrete Retaining Wall on Heelpath of Erie Canal

Experimental Levees with Concrete Paving and Sheet-Pile Cutoff, Mississippi River

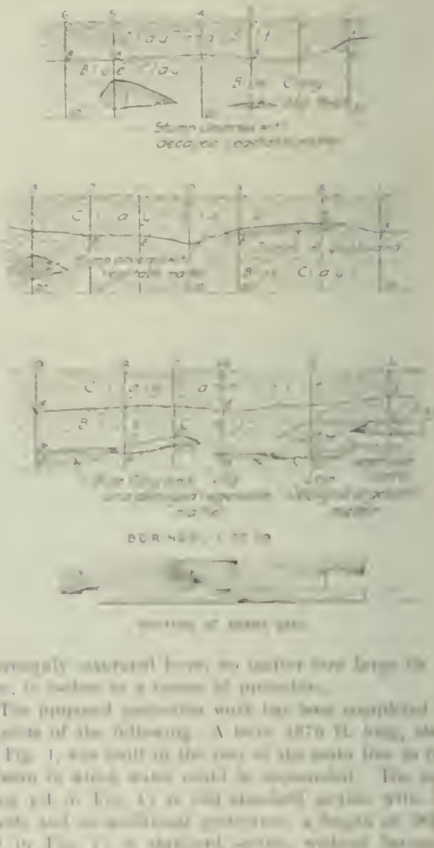
By C. O. SHERRILL*

The years 1912 and 1913 were characterized by the greatest floods ever known on the Mississippi River, and efforts of the United States Government and the local engineers to hold these floods between the levees are well known to all. These efforts, in effect, were directed against 2,200,000 cu.ft. per sec. of water flowing down the river between levees constructed to grade for 1,750,000 cu.ft. per sec. As a result, all the levees were strained to the utmost and many proved unsafe, or sloughed and had to be reinforced.

It was found that in certain classes of soil excessive seepage and sand boils occurred, even in the most carefully built levees. To determine the effectiveness of various types of protection, the Fourth District, Mississippi River Commission, undertook certain experimental work, described below, with a view to determining whether a standard-section levee protected with granite concrete, [illegible] and with interlocking sheet piling, extending 20 to 30 ft. deep, on the land or the flood side, will decrease the percolation of water through the levee so as to keep it dry for the long period of highest flood, usually 30 to 60 days.

FIG. 1. EXPERIMENTAL LEVEE WITH PAVE PROTECTION AND PILE CUTOFF AT UPPER LATTERMAN, MISSISSIPPI RIVER

The writer undertook these experiments with the idea that the protection of levees in this way would add greatly to the resistance of the water passing through the levee, due to the necessity of its passing over the longer path around the bottom of the sheet piling and upward toward the surface against gravity and frictional resistance of the soil, and that for the period during which levees are subjected to the pressure of flood water this increased resistance to percolation would probably delay the rise of the seepage plane sufficiently to allow the levee to remain dry until the danger was passed. It has been thoroughly demonstrated, however, that a dry levee of any size practicable to build is a safe levee, and that any



thoroughly saturated levee, no matter how large its section, is liable to a failure of protection.

The proposed protection work has been completed and consists of the following: A levee 1870 ft. long, shown in Fig. 1, was built in the rear of the main line to form a basin in which water could be impounded. The upper wing [illegible] is a standard section with [illegible] and no additional protection; a length of [illegible] ft. [illegible] is standard section without [illegible], and has [illegible] concrete slabs for flow protection and 20-ft. sheet-pile protection; the remainder [illegible] has a [illegible] crown, and slopes of 1 on 3, with a [illegible] granite face protection and 29-ft. wood interlocking sheet piles.

A length of [illegible] ft. [illegible] has concrete and interlocking steel-pile protection, placed at the expense of the Lackawanna Steel Company to test their new [illegible] steel interlocking piling. [illegible] ft. of steel piling, [illegible] lb. per sq.ft., was of Lackawanna beam type [illegible], driven 20 ft. deep. This piling proved easy to drive, as there was no tendency for the piles to twist, either at top or bottom, due to the construction

*Major, Corps of Engineers, U. S. A.; District Engineer, Fourth District, Mississippi River Commission, New Orleans, La.

FIGS. 2-5. VIEWS OF EXPERIMENTAL LEVEE BEFORE FILLING

(Fig. 2. General view of basin. Fig. 3. Small section levee, one on two slopes, 5-ft. crown, 2-in. Gunite face protection, wood sheet piles. ("C" in Fig. 1.) Fig. 4. Levee with one on three slopes, 8-ft. crown, 4-in. concrete slab protection. ("B" in Fig. 1.) Fig. 5. Standard Levee, 8-ft. crown, one on three slopes and 20-ft. banquette. No protection. ("A" in Fig. 1.)

Practically all the piles were driven full 20-ft. penetration with an average of 20 blows per double pile. A drop hammer weighing 2350 lb., with a fall of 12 ft., was used.

There had been previously used by the Fourth District office various types of wood piles for levee protection, including Wakefield, dovetail-interlock, spline and groove, and tongue and groove, but none of these can compare with the standard interlocking type, patented by Alexandria Lumber Co., Alexandria, La., and shown in Fig. 1, as to ease of driving and water-tightness. The steel piling gives a good interlock, but on account of its light section was difficult to drive in the hard soil found at Fairfield; and it costs considerably more than wood. The Lackawanna Steel Co., however, is experimenting further with this piling, and it is believed that with a properly designed steam hammer and driving cap it can be satisfactorily driven in the hard soil at this locality. The writer saw some of it driven with success at the Lackawanna plant in comparatively soft ground. There is some doubt whether it will last for any great length of time unless made of special nonrusting composition.

Upon the surface of the protected portions of the levee was placed either ordinary concrete (1:3:5) 4 in. thick, or gunite, 2 in. thick. The gunite was placed on a levee of small sections, namely: 5-ft. crown, with slopes 1 on 2, to give it as severe a test as possible in comparison with the ordinary concrete. The 4-in. monolithic concrete was placed on a levee having 8-ft. crown and slopes 1 on 3. The largest section levee, which is the standard Mississippi River Commission type, was left unprotected in order to have a direct comparison between this levee's efficiency and that of the smaller protected sections.

Gunite was placed on the levee in several different

FIG. 6. SECTION OF THE INTERLOCKING WOOD PILING COVERED WITH CONCRETE

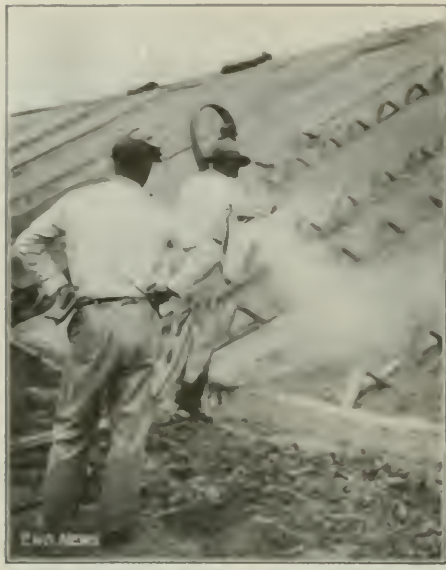


Fig. 7. Placing Gunite on Face

Fig. 8. Gunite in Place

Figs. 7-8. Gunite Protection of Levee Face

ways: (a) Directly on the levee itself; (b) on the levee with light reinforcement; (c) on gravel spread on the levee with reinforcement on the top; (d) on gravel with no reinforcement. In each case, the top of the sheet piling was covered for one foot down with gunite reinforced by light wire mesh. The last method named, that is, gravel with no reinforcement, having proved most satisfactory, it was adopted for the bulk of the work. The gravel was spread 2 in. thick on the levee and was then treated with gunite to cement it in place. This was found to give a dense concrete practically impervious to water, as was shown by a basin constructed by this effort.

Fig. 9. Top of Gunite Slab

Fig. 10. Bottom of Gunite Slab

This basin was hopper shaped, 4 ft. square at the top, 2 ft. square at the bottom and 2 ft. deep, and was constructed with a 2-in. layer of gravel treated with gunite. After this gunite had set, the basin was removed from its earth form, and being placed on timber supports and filled with water, it was tested as to percolation, with the result that it was found to be practically water-tight after a week's test. This mixture consisted of one part cement to 3 of sand and 3 of gravel.

After experiments in placing the gunite by the various methods mentioned above had been made, it was found that the products secured by spreading a layer of 2-in. gravel ranging from ½ to 2 in. in diameter and treating with very wet gunite of one part cement and three parts sand gave an impervious dense mixture 2 to 3 in. thick at a cost of about 33⅓% less than the ordinary 1:3:5 concrete mixture 4 in. thick.

Four sets of test wells, four wells in each set (Fig. 1), were driven and lined with porous terra cotta pipe, in order to determine the rate and amount of rise of the plane of percolation of water through the levee under the head caused by the filled basin. On account of the saturation of the levee by heavy rains previous to the filling, it was found that water in the wells driven through the center of the levee rose about 12 ft. above the natural ground surface before any water was pumped into the basin. It is proposed to continue the test during the dry fall months, in order to definitely measure the effect of protection work on the surface of percolation as compared with that in the unprotected portions.

The U. S. dredge "The Ram" pumped the basin full of water up to 41.8 ft., Cairo datum, 0.6 ft. below the 1912 high water, between July 18 and 25. On July 27, a slough occurred 80 ft. long at its base which took out 3 ft. of the crown at the point marked X (Fig. 1). It had been the intention to raise the water about 1½ ft. higher, but due to this dangerous slough of the old main levee, which threatened to cause a crevasse toward the river, the pumping was discontinued. At this time, the landside of the threatened main levee was blanketed with earth and the entire length of this main levee between the ends of the experimental levee was thoroughly drained on the river side to carry off the seepage as fast as possible, in order that a crevasse might not occur in this levee before the experimental sections should have had a thorough test.

On Aug. 5-6, the water was further raised to 0.4 ft. above the 1912 high water. Two days later a slough occurred at Y (Fig. 1), taking out 1½ ft. of the crown, and but for prompt protective work a crevasse would have occurred on this date.

The first seepage in the new experimental levee began July 23, in the standard full section unprotected levee near its junction with the main levee and has continued increasing to date. The second seepage began July 29 at the landside toe of the levee at Station 3693 behind the concrete-protected levee. The third seepage began Aug. 8 on the landside slope opposite Station 3690 + 60, about 15 ft. up from the toe. The seepage at these two places covers small areas about 6 to 8 ft. in diameter and of small amount. No seepage whatever has occurred in the small section levee itself or in the fields behind the small section levee protected with interlocking sheet piling and 2-in. gunite facing. The basin has been filled with water more than a month at this time, which is a considerably longer period than the levees are usually subjected to the strain of the highest water of the Mississippi River floods, as the extreme height is reached gradually and the water at once begins to subside. The behavior of the protected sections as compared with those unprotected indicates the superiority of protected levees of small section over the larger standard sections of earth alone.

The old main levee, although subjected to a much lower head, and though having a larger section than the protected portions, began to seep throughout its entire length shortly after the basin was filled and continued to grow worse from that time onward. The new standard section has also shown considerable seepage in its upper portion; the concrete-protected levee has seeped at only two small places. The smaller section gunite and sheet-pile protected levee has shown no seepage. The levee itself and the fields in the rear remain dry. The two seepage areas behind the concrete protection can probably be explained by the fact that in driving the sheet piling two logs, buried from 10 to 15 ft., were struck by the piles, which were badly shattered and probably did not make a tight cutoff wall at those points. It is also possible that the seepage at these points was caused by cracking of the concrete, due to the excessive subsidence of the levee where extensive slides had previously occurred and had been replaced in the construction of the levee. In localities where levees are subjected to wave-wash or where the land on which to build the levee is expensive the protection is especially valuable.

Tables have been compiled showing that for heights over 16 ft. the smaller levee with gunite and interlocking wood sheet piling with 10-ft. penetration costs less than the standard large unprotected levee. For the heights up to 16 ft., the standard small levee costs more than the large unprotected one.

Payment for Construction Charges of Irrigation Projects carried out by the Reclamation Service will hereafter be distributed over a period of twenty years, instead of ten years, as heretofore. This change is the result of a recent Act of Congress. Under the act, 5% of the construction charges against any land owner will be paid as an initial installment, and the remainder due will be paid in 15 annual installments, but the first of the 15 installments will not be due until Dec. 1 of the fifth calendar year after the initial installment. The first five of the 15 installments will be at the rate of 5% of the construction charge, and the last ten at the rate of 7%. The change in the period allowed for payment will apply to land owners under existing projects, so far as balances due are concerned; but such balances would be payable in 20 instead of 15 annual installments, the first four installments at the rate of 2% per annum, the next two installments at 4%, and the next 14 at 6% of the total construction charges unpaid when the law goes into effect. The act also prohibits any increase in the construction charges after these have once been established, except on agreement between the Secretary of the Interior and a majority of the land owners affected. The Act further provides for "an operation and maintenance charge based upon the total cost of operation and maintenance of the project, or each separate unit thereof and such charge shall be made for each acre-foot of water delivered; but each acre of irrigable land, whether irrigated or not, shall be charged the minimum operation and maintenance charge based upon the charge for delivery of not less than one acre-foot of water." The Act authorizes the Secretary of the Interior to make general rules and regulations regarding the use of water in any project, and also authorizes him to "require the reclamation for agricultural purposes and the cultivation of one-fourth the irrigable area under each water-right application or entry within three full irrigation seasons after the filing of water right application or entry, and the reclamation for agricultural purposes and the cultivation of one-half the irrigable area within five full irrigation seasons after the filing of the water-right application or entry."

Tests of a Deep-Well Irrigation Pumping Plant

By Geo. S. Knapp*

While most of western Kansas consists of semiarid plains having an altitude of 2000 to 3000 ft., it has an almost unlimited supply of underground water suitable for irrigation. At a depth of 10 to 60 ft. in the Arkansas Valley, and 80 to 150 ft. on the uplands, is a water-bearing gravel extending to a depth of several hundred feet. The gravel is coarse so that the water flows to the wells very rapidly. Most of the wells furnish 2000 to 3000 gal. per min., and will supply this amount continuously without any apparent decrease in the supply.

The richness of the land and of the climate, combined with the cheapness of the land and the abundance of water, have led homeseekers and capitalists to buy up these lands and convert the great ranches of a decade ago into productive fields. The United States Sugar & Land Co. has about 5000 acres, nearly all irrigated by pumping and used for growing sugar beets and alfalfa. The company is constructing a large electric power plant to supply power to the farmers for pumping.

The field of irrigation by pumping from deep wells is a comparatively new one, and is yet in the experimental stage. The question of economical pumping is a large one and the development of efficient machinery to handle large quantities of water at the high heads will go far toward solving the problem.

There are at the present time three distinct types of pumping plants: (1) the plunger pump operated by a windmill; (2) the common horizontal centrifugal pump used where large quantities of water are required and the head is not too great; (3) the deep-well turbine centrifugal pump. The chief advantage of the windmill plant is the low cost of operation. But in order to make use of the power whenever the wind is blowing, and to have a ready supply of water whenever it is desired to irrigate, a large and ofttimes expensive reservoir must be built. To get a sufficient supply of water, several wells may be put down around the reservoir and a windmill erected over each. It is not uncommon to see five to ten windmills pumping into one reservoir.

With the horizontal centrifugal pump, it is possible to pump water enough to irrigate directly from the pump, the plant being run only while irrigating. This saves the expense of a reservoir and eliminates the loss of water by seepage and evaporation from the reservoir. The pump is placed usually in a pit about 10 ft. below the surface to reduce the suction head, and is driven by a belt from above. With this type of plant, it is usually better to put down several small wells rather than one large one, and pipe all to one pump. Near Garden City, Kan., is a plant of this kind with five wells about 50 ft. apart, connected to one pump driven by an oil tractor. This plant has a capacity of 3000 gal. per min.

The deep-well pumping plant differs from the others principally in the type of pump used. The pump (consisting of several stages) is placed near the bottom of the well and is supported entirely by the piping, as shown in Fig. 1. The driving shaft is vertical and is enclosed in a protecting pipe inside of the discharge pipe, which serves the double purpose of protecting it and keeping it in alignment. A thrust bearing in the head carries the weight of the shaft and the revolving parts. The entire weight of the pump is carried by the head, which rests on the well casing. The pump is driven either by an engine (with a quarter-twist belt) or by a direct-connected motor.

For the purpose of investigating the success of pumping, the cost of equipment, the duty of water, and the methods of applying it, a pumping plant of this last type has been installed near Garden City, Kan., to irrigate 80 to 160 acres, and is operated by the cooperation of the U. S. Department of Agriculture and the Division of Agriculture of the Kansas State Agricultural College. In the spring of 1913, the writer spent three months at the plant and during that time made a number of tests.

*Superintendent, Experiment Station, Kansas State Agricultural College, Garden City, Kan.

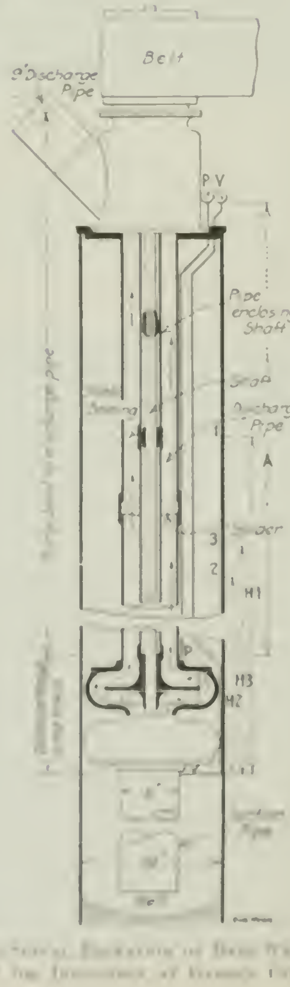

Fig. 1. Sectional Elevation of Deep-Well Pumping Plant for Irrigation at Garden City, Kan.

Description of the Plant

The well is 24 in. diameter, 100 ft. deep, cased with No. 8 steel (U. S. gage). The lower 30 ft. of this is a perforated strainer. A log of the well shows 47 ft. soil, 7 ft.

soft limestone, 6 ft. gravel, 2 ft. sandstone, 35 ft. No. 8 sand, 30 ft. No. 9 sand, 16 ft. No. 10 sand, balance fine sand and soft limestone. The water stands at 71 ft. in the well when the pump is not in operation, and draws down to about 110 ft. when supplying 650 gal. per min.

A two-stage pump with 8-in. suction and 9-in. discharge, has its shaft belted to a fuel-oil engine. The pump bowls are 120 ft. below the surface. Below this is 40 ft. of wrought-iron suction pipe without foot valve or strainer, this pipe being for the purpose of keeping the well free from sand. The shaft and moving parts of the pump are carried on a ball thrust-bearing in the pump head. The protecting pipe incloses babbited bearings placed 6 ft. apart to keep the shaft in alignment, and this pipe in turn is supported at 20-ft. intervals by spiders fastened in the couplings of the discharge pipe. The shaft is lubricated by the overflow from the main bearing at the top flowing down around the shaft. The discharge from the pump is into a concrete weir box, shown in Fig. 2, from which the water flows over a Cippoletti weir (with 24-in. crest) to the ditches.

The oil engine is horizontal, single cylinder 16x24 in., single-acting, throttle governed, and rated at 75 hp. It operates on fuel oil of about 39° Baumé and about 17,-200 B.t.u. per lb. The fuel is pumped by the engine from a 10,000-gal. supply tank outside of the building and passes through coils in the exhaust pipe which heat it nearly to the boiling point before entering the carburetor. To facilitate starting, a 60-gal. tank is provided for gasoline which is used until the engine becomes warm enough to vaporize the distillate. Three-way cocks on the engine make possible an instantaneous change from one fuel to another. An additional fuel tank is provided for measuring the fuel during a test. Compressed air for starting is stored at 150 lb. pressure in two tanks having a capacity each of 4 cu.ft. of compressed air. These are charged by a small compressor driven by the engine.

The engine is housed by a concrete building, and the pump and belt way by a frame structure covered with corrugated steel. The large fuel tank is of steel and is set in a concrete-lined pit and covered with a shingled roof. A derrick over the well to assist in pulling the pump, and a few necessary tools complete the equipment of the plant. The cost of the plant is as follows:

Engine, complete on foundation		$1705
Pump, complete in well		764
Well:		
Drilling well and setting pit and strainer	$1136	
90 ft. of 24-in. strainer	900	
90 ft. of 24-in. steel pit	315	
Hauling supplies, etc.	382	
Total cost of well		2733
Building		446
Storage tank		202
Belt, weir box, labor, etc.		375
Grand total		$6225

Tests

A number of tests were made during the summer, but many of them either did not give results of any value or were not continued enough to warrant publishing the results. Several attempts were made to obtain curves of the pump, since its efficiency was low and the curves would have been of considerable value in studying the causes of the low efficiency. Nothing of any value was obtained, however, because of the limited range through which the conditions could be varied. The head could not be reduced below about 80 ft. and as there was no means of regulating it, it increased in proportion to the quantity of water pumped, due to the lowering of the water in the well. The pump speed also could not be varied, as the speed of the engine could not be changed more than about 5% above or below normal, and there was not power enough to admit of putting smaller pulleys on the pump to get higher speeds.

The two tests in the accompanying table best show the operation of the plant. The first represents the ordinary working conditions, and in the second, the conditions are improved somewhat. After the first test the valves on the engine were carefully ground and timed, and the piston rings (which were leaking badly) were turned and fitted. This resulted in such an increase in

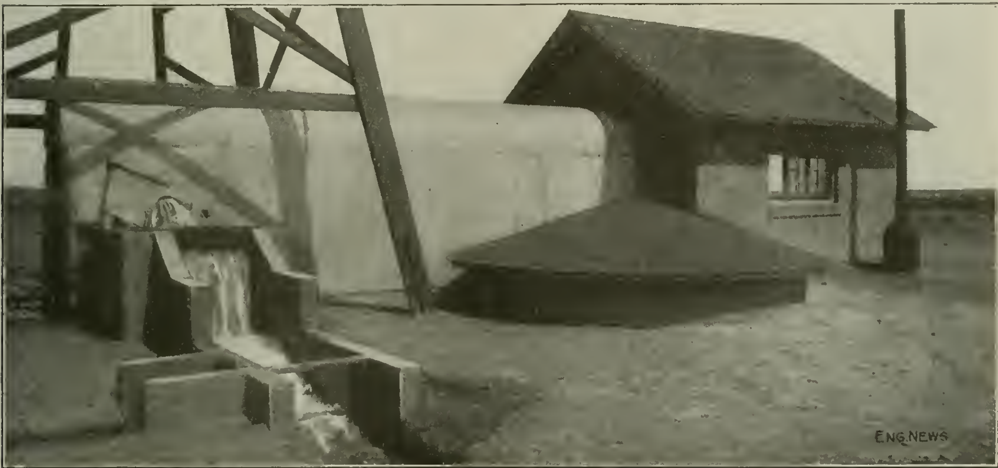

Fig. 2. Deep-Well Pumping Plant for Irrigation at Garden City, Kan.

(The oil engine is in the small house, with inclosed belt gallery to the well. The discharge from the pump flows to the concrete weir box. Adjacent to the pump house is the top of the tank for fuel oil. The derrick over the well is for handling the pump.)

power than it was possible to use a pulley of [illegible] smaller diameter on the pump, thus getting an increase in pump speed.

As the conditions remained practically constant during the tests, readings were taken only at 30-min. intervals, the averages of which being taken in the final computations. The horsepower was found by indicating the engine, and the power delivered to the pump was obtained by multiplying this by the mechanical efficiency of the engine and making a correction for belt slip. A subsequent test on the engine by loading it with a rope brake gave a mechanical efficiency of 82% at the load required by the pump. The belt slip was 4.8% in the first test and 6.5% in the second. The fuel was weighed each time the small tank was refilled. The discharge over the weir was determined by measuring the head and referring to a previously prepared head-discharge curve for that weir.

TESTS OF DEEP-WELL IRRIGATION PUMPING PLANTS

Cost per [illegible]	[illegible]		5.1[illegible]

The prices given do not include labor to spread the water in the field, nor interest and depreciation on the plant. The cost of pumping was reduced considerably in the second test. This must be due to a better pump efficiency at the increased speed, since the fuel consumption of the engine was the same. From the fact that a [illegible]% increase in power in the second test resulted in a [illegible]% increase in pump speed and a 16.6% increase in discharge at a slightly increased head, we may conclude that the pump is operating below the most efficient speed for that head. No better speed could be obtained, however, as the engine was loaded to its maximum capacity in both tests. From the results of these tests it appears that the engine does not deliver its rated power in the belt. Probably much of this deficiency is due to the rarefied air at this altitude (4000 ft.), which reduces the volumetric efficiency of the engine. The engine comes within the manufacturer's guarantee, however, as the specifications only required the engine to deliver [illegible] b.hp. at this altitude.

Testing the Pump

A test of this type of pump presents some features not met with in the more common types. Gages were connected above and below the pump bowls to determine the head, the pressure gage being [illegible] ft. and the vacuum gage [illegible] ft. below the ground level. If any readings were taken separately on the gages, they were not used in computing the total head on the pump, for reasons which follow.

It is much more difficult to determine the suction head with a pump of this type than with an ordinary centrifugal pump, because the height of the water in the pipe P (Fig. 1) leading to the vacuum gage cannot be determined with any certainty. This must be known to determine the suction head. This is due to the following causes: When the pump is not running, the water in the well stands at some point 1, and there is a static head H-1 at the entrance to the pump. When the pump is in operation, the water draws down to 2, and the static head at entrance is H-2. The water in the small pipe P will not remain at 1, neither will it fall to 2, but as the pressure is reduced at the pump entrance as the pump is started, the column of water will fall and the air above it will expand until a condition of equilibrium has been obtained. This will allow the water to fall to some point 3 and the static head will be H-3, the actual head at entrance being the algebraic sum of the head H-3, and the gage reading reduced to feet.

It yet remains to find the value of H-3. This can be done by considering the expansion of the air column as isothermal and applying the law $PV = pv$ where P and p are the initial and final absolute pressures, and V and v are the initial and final lengths of the air column above the water level in the small pipe. In the second test: $V = 71$ ft.; $P = 26.7$ in. of mercury, $p = 26.7 - 7.8 = 18.9$ in. mercury. Then $v = (71 \times 26.7) \div 18.9 = 100$ ft. And H-3 $= 124 - 100 = 24$ ft. The average gage reading during the run was 7.8[illegible] in. of mercury = 8.8 ft. of water. The head at the pump entrance then is $24 - 8.8 = 15.2$ ft.

In this plant the pump is submerged until there is a positive head at entrance. This method will give the true head only if no air has leaked into the pipe, for if there is any leakage, H-3 may drop until the gage will read zero even though there is a considerable suction head. This possibility of leakage makes this method very uncertain.

Another method of determining the head at the pump entrance is to find the loss of head below the pump and subtract such loss from H-2. This loss consists of the friction head in the suction pipe and the velocity head. Since there was neither foot valve nor strainer on the suction pipe, we can allow the usual friction for iron pipe for the friction head. Merriman's "Hydraulics" gives 0.[illegible] ft. as the friction head for 10 ft. of 8-in. iron pipe with a velocity of [illegible] ft. per sec. The velocity in the suction pipe was [illegible] ft. per sec., from which the velocity head [illegible] = 0.2 ft. Dropping a float to the surface of the water showed that H-2 was 16.[illegible] ft. The head at entrance then is 16.[illegible] − [illegible] = 15.[illegible]

The head is 0.5 ft. more by this method. While there is always some uncertainty in regard to the friction head, it is always small, and the liability of error will probably be less by the latter method. This was the method used to compute the suction head in the foregoing tests.

There is no difficulty in determining the head above the pump by the use of the pressure gage. If a cock is opened at the top of the pipe when the pump is started the water will rise and expel the air; thus the head in the pressure-gage pipe is be added to the pressure-gage reading is known. It is readily seen, however, that in a pump of this type the loss of head between the pump bowls and the discharge is governed largely by the manufacturer's design. Obstructions, such as the spiders to hold the protecting pipe in place, as well as the pipe itself, may cause a considerable friction head.

In a test to determine the performance of the pump proper at various heads it is desirable to have a gage [illegible]

mediately above the pump bowls. But in a test where the object is to find the efficiency of the installation, any losses between the pump bowls and the discharge pipe should, in the opinion of the writer, be charged to the pump. Then a gage should be placed in the discharge pipe above the pump head if there is any head above that point. On this pump the discharge pipe was less than 2 ft. long, and the friction is negligible; and as there was no pressure head the velocity head can be taken as the total head at that point.

Under the former method the head is 110.8 ft., but if computed by using the pressure gage it will be 120.1 ft. This is 9.3 ft. greater, the difference representing the head lost between the pump bowls and the discharge pipe. If this were not charged to the pump the efficiency would be 36% instead of 33%, as given in the table.

Piles of Unusual Length are to be driven to support the falsework of the Mississippi River Bridge which is under construction for the Rock Island R.R. at Memphis, Tenn. An order for 120,000 lineal feet of piling is being filled in the coast forests of Oregon. Some of the piles are 111 ft. in length. The felling and handling of these very long slender timbers is a task of no small difficulty. The piles are shipped out of the woods on a logging railroad with 15° curves, which is about the limit of curvature over which such long piles could be handled. For shipment east, the piles are loaded on flat cars with an intermediate idler car.

Trainshed of the Kansas City Union Station

The trainshed of the new station of the Kansas City Terminal Ry., Kansas City, Mo., is of the low-roof multiple-span type now very generally used in preference to the lofty single-span arch roofs that were largely favored at one time. It has a very unique feature, however, in the use of one wide opening over each pair of tracks instead of a narrow opening or smoke slot over the center of each track. Fig. 1 is a view of the completed steel work of one span, showing the skylight covering

FIG. 1. TRAINSHED OF THE NEW UNION STATION OF THE KANSAS CITY TERMINAL RY., KANSAS CITY, MO.

and (at the right) the vertical concrete slabs forming one side of the wide ventilating opening. The slabs on the left side had not been placed. The roof and window which appear through the open top of the trainshed are part of the waiting room, which occupies a one-story building spanning the tracks.

The roof framing consists of a row of steel columns along the center of each platform, supporting longitudinal trusses of 34 ft. span and main trusses of 44 ft. span. The columns are spaced 34 ft. apart longitudinally and the main trusses 17 ft., the intermediate trusses being carried by the longitudinal trusses. Over the outer platform there is an extension of the roof supported by cantilever trusses. The main trusses have in-

A Tight Job of Water-Main Laying at Akron, Ohio*

By E. G. Bradbury†

In designing the extensive improvements to the water-works of Akron, Ohio, F. A. Barbour [Boston, Mass.] and the writer specified, after much consideration, a maximum permissible leakage of 200 gal. per inch-mile daily—equivalent to about 1.6 gal. per ft. of lead joint.

The pipe laid at Akron comprises new supply lines, lines paralleling and reinforcing old mains of insufficient capacity, and extensions into streets not heretofore furnished with water. The new supply lines and reinforcing mains are laid by contract under the supervision of the designing engineers, E. A. Kemmler, Department Engineer, being in immediate charge, while the extensions are laid by employees of the city under H. H. Frost, Superintendent of Water-Works. All pipe is purchased by contract and is inspected at the foundry by experienced men. The depth of lead specified is $2\frac{1}{4}$ in.

The method used in all tests was as follows: After completion of laying, the pipe was filled with water and usually allowed to stand for about 24 hr. to permit the yarn in the joints to become saturated. The pipe having been tapped for a $\frac{3}{4}$-in. connection, a small hand pump was connected by wrought-iron pipe and fittings, on which a gage was set, the suction being placed in a barrel of water. All gates were then closed and a hydrant valve opened to determine whether gate leakage existed in amount sufficient to flow. The depth of water in the barrel and its diameter at water level were then measured and pumping begun. If the pressure was readily raised to the required amount the time was noted, and the amount of water required to hold the gage stationary for a period of from 10 to 30 minutes carefully observed. The leakage was computed from the quantity so used. If too great difficulty was found in raising the pressure, or if the leakage was found to exceed the allowed quantity, pumping was stopped and the gage observed to see it if would remain stationary after dropping to city pressure, thus indicating gate leakage; if such leakage was not demonstrated, effort was made to find defects in the pipe. In one or two instances pipe which could not be pumped up to pressure on the first trial were successfully tested on the following day, no satisfactory explanation being found. In a considerable number of cases the contractor was required to locate leaks and recalk joints, sometimes causing the reopening of the trench for considerable distances. In two cases, cracked pipe were located and removed.

The final results of the tests have been very gratifying. A total of 100 tests have been made of pipe laid by contract, of which 86 are included in the accompanying table. Of the remaining 14, there were eight in which all joints were visible and no leakage existed, but on account of loss through gates, no measurement was made; three in which the measured loss somewhat exceeded the specified maximum but evidence of gate leakage was such as to satisfy the engineers that the specifications were complied with; and three in which the leakage was above the specified amount and the work not accepted. Of 40 tests made by the superintendent of water-works of pipe laid by his department employees, 38 have been tabulated, the remaining two exceeding the permissible loss; these are to be dug up if necessary to locate and repair the leaks.

TABLE I. SUMMARIZED RESULT OF TESTS OF PIPE LAID BY CONTRACT AND BY THE SUPERINTENDENT OF WATER WORKS, AKRON OHIO

Size, in.	Length, ft.	Leakage, gal. daily per in.-mi.	Number of tests
86 TESTS OF PIPE LAID BY CONTRACT*

30	14,445	82	8
	88,476 (16.76 mi.)	83.4	86
38 TESTS OF PIPE LAID BY SUPERINTENDENT OF WATER-WORKS			
6	37,524	59	32
8	6,509	63	5
10	2,859	133	1
	46,883 (8.9 mi.)	61.7	38

*Pressure from 66 to 152 lb.—35 greater than static head when improvements are complete.

All the above figures are probably high, as they include whatever leakage may have occurred through gates, as well as actual loss. Such leakage was known to exist in many cases, and in 20 of the tests of pipe laid by contract and included in the above summary, every joint was visible and tight, although usually some water was required to keep up the pressure. The amount pumped also covers any contraction or absorption of air contained in the pipe. The presence of any considerable amount of air makes the tests unsatisfactory and occasionally it becomes necessary to tap the pipe to release it.

Check tests of 24- and 30-in. pipe, made several months after the original test in two districts of about one mile each, verified closely the previous work, showing losses of 55 and 79 gal. per in.-mi., respectively.

Assuming the average diameter of pipe in a complete system to be 9 in., each 100 gal. daily per in.-mi. saved or lost has a value of $3.28 per year for each mile of pipe at a production cost of $10 per million gallons, or, capitalized at 7%, is worth $46.86. Applying these figures to a concrete example, a city of 100,000 population with a production cost of $25 per million gallons, and 160 miles of mains, would gain $5626 per year by a saving of 400 gal. per in.-mi., and figuring interest and sinking fund at 7%, could afford to have spent $75,100, or about $470 per mile more on construction to accomplish this result, and the same amount lost per inch-mile would cost a city of 200,000 population with 300 miles of mains and a production cost of $50 per million gallons $19,700 per year—equal to an investment of $281,430.

The expense of testing in the manner described is not heavy, averaging about $50 per mile. Occasionally, where careless work has been done and the pipe covered, the contractor foots a rather heavy bill of expense, but the knowledge that the work is to be tested discourages carelessness and most of the tests are made quickly and without trouble.

In view of all the above facts the writer proposes as a standard for allowable leakage in new cast-iron water pipe, an average of 100 gal. per mi. per in. of diameter for each complete contract or district, with a maximum limit of 200 gal. per mi. per in. of diameter not to be exceeded in any single test. The recommendation

A Reinforced-Concrete Pile with Special Provisions for Jetting

[illegible]

Water is supplied at a pressure of 100 to 150 lb. per sq.in. [illegible]

The average time to sink a 50-ft. pile is about 12 [illegible]

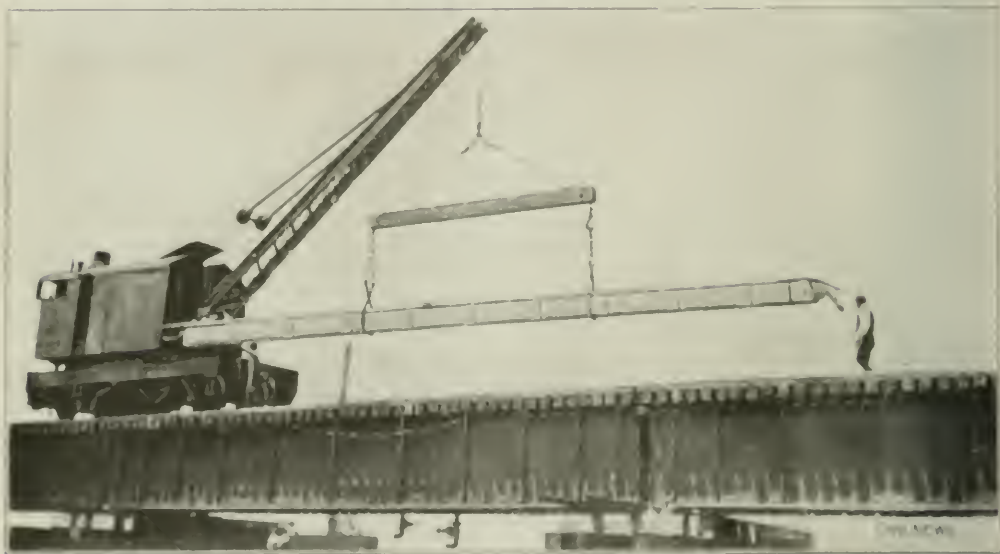

Fig. 1. [illegible] Pile Into Place

[illegible]

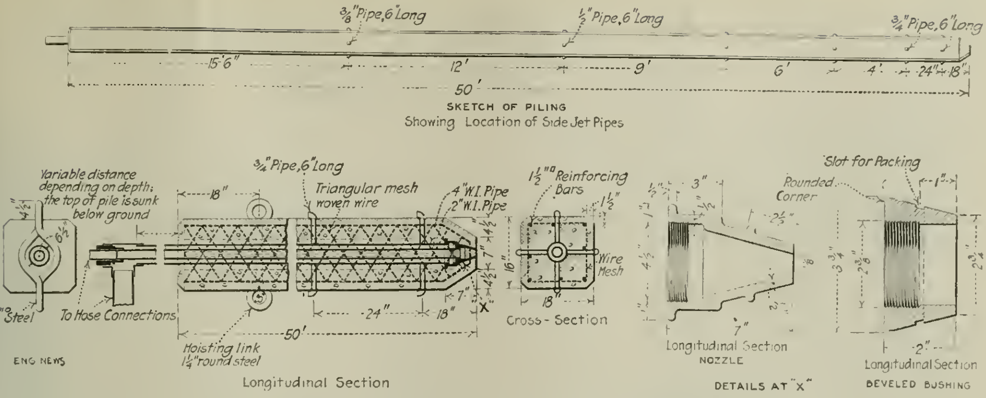

FIG. 2. DETAILS OF THE BIGNELL REINFORCED-CONCRETE PILE

The cost of manufacturing piles used on the Platte River Bridge was 53c. per lin.ft., excluding the cost of freight on the material. The piles were cast at Havelock, Neb., for convenience in using the yard equipment and were brought some 24 mi. on flat-cars to the job. The cost of sinking the whole is not known since the cost statement for work at the bridge includes work and material not charged for the sinking of piling. An estimate based on labor amounting to $40 per day and a liberal amount for the use of equipment and overhead charges gives the cost of sinking not to exceed 15c. per lin.ft., where the job amounts to not less than 10,000 ft. of piling. For a small job the total cost of piling in place is estimated to be about $1 per ft. up to lengths of 50 ft.; $1.07 for piling 80 ft. long, and 59c. per sq.ft. for sheet piling, which is of similar general design as the square piling shown, but which is provided with tongue-and-groove sides for the joints.

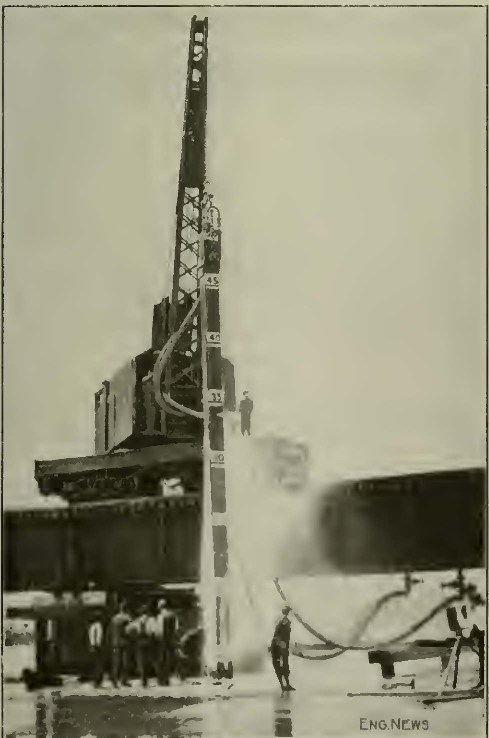

FIG. 3. A BIGNELL PILE BEING WATER-JETTED INTO PLACE

(Note water spurting from side nozzles).

Water Storage in the Naugatuck Valley, Conn., for the benefit of manufacturers and others, has been under consideration for some time past by a committee representing the manufacturers. Continuing the information given in a note published on p. 1221 of our issue of May 28, 1914, it may be stated that Charles H. Preston, Jr., consulting engineer, of Waterbury, Conn., has been engaged to make surveys, maps, borings and soundings for the project. Of several schemes available for storage purposes, Lead Mine Brook has been chosen for possible development, and the surveys will be conducted at three possible sites chosen on this stream. Preliminary estimates indicate that three reservoirs could be provided by the construction of dams at a total cost of about $1,000,000. These reservoirs would have a combined storage capacity of about 23,000,000,000 gal. Lead Mine Brook enters the Naugatuck River near Thomaston.

The Malleable Iron Industry dates from a patent obtained in 1804 by an Englishman, Samuel Lucas. In the United States, Seth Boyden first made malleable castings in Newark, N. J., in 1826. About 250 firms in this country now produce malleable castings, the total output being about 1,000,000 tons per year. The industry is almost exclusively an American one, malleable iron being made in Europe only on a very limited scale. The most rapid growth in the industry has occurred during the past twenty years. In that time malleable iron has almost entirely replaced cast iron in freight car construction and in agricultural implement manufacture. A good malleable iron should have a tensile strength of 35,000 to 55,000 or even 60,000 lb. per sq.in., with an elongation of 3% to 8% in 2 in. The above statements are taken from a paper on malleable iron read by J. P. Pero at the Chicago meeting of the American Foundrymen's Association on Sept. 7. Mr. Pero further says:

Its greatest advantage is the fact that the metal is not subject to crystallization or fatigue, but will stand as severe a test after twenty or twenty-five years of use as it will when originally made, no matter how great the vibration may have been to which it has been subjected.

If proper care is used in its manufacture, it should also be quite free from internal flaws, such as blow holes or shrinkage flaws, and the metal, while it will stand considerable abuse and distortion before breaking, is much more rigid and will resist the tendency to become distorted to a greater extent than either drop forgings or steel castings of the same sections.

Malleable iron also resists rusting or corrosion very much better than either wrought iron and steel, running only slightly below cast iron in its resisting qualities to oxidation

The New York Rapid Transit Railway Extensions

II--Organization and Personnel of the Engineering Staff*

[illegible] in New York City, [illegible] of constructing [illegible] miles of rapid-transit [illegible] and through the heart of the most congested districts of New York City—a system of elevated and underground electric railways of far greater mileage and more complete in every respect than any similar system in the world. This work is being carried on under the direction of the Public Service Commission of the First District of the State of New York, which besides having direct charge of the construction of these new Rapid Transit lines also supervises the operation of all Public Utilities companies, [illegible] and passes upon equipment, services and rates of all existing transportation lines, whether Surface, Rapid Transit, Interurban or regular steam railroads, etc., as well as gas, electric light, power and telephone companies.

ORGANIZATION

The chart, p. [illegible], shows [illegible] the organization of the engineering staff engaged in subway and rapid-transit design and construction and incidental work. [illegible]

[illegible]

PROMOTION EXAMINATIONS—An example of such an examination was one held a year ago for the position of Assistant Division Engineer. This was open only to Assistant Engineers and Designers of Grade 10. The subjects of the examination and the relative weights were: (a) A paper on some subject relevant to the work of the applicant, weight 1; (b) efficiency, weight [illegible]. The paper was to be typewritten and illustrated with drawings or photographs, and accompanied by an affidavit to the effect that it was an original composition of the applicant. The practicability of such a test is readily appreciated and illustrates how an enthusiastic, loyal and efficient staff may be built up and maintained, while still keeping strictly both to the letter and the spirit of the civil-service laws.

DUTIES OF EACH RANK—The specific duties of the members of each rank (in the subordinate positions there are several grades in each rank according to salary) are given below.

CHIEF ENGINEER—In general charge over all work under the Engineering Department, including the preparation of plans for and the construction of subway and elevated work by the City, and the approval of plans for and supervision over the construction and equipment of subway and elevated lines by the operating companies [illegible]

ENGINEER OF SUBWAY CONSTRUCTION—[illegible]

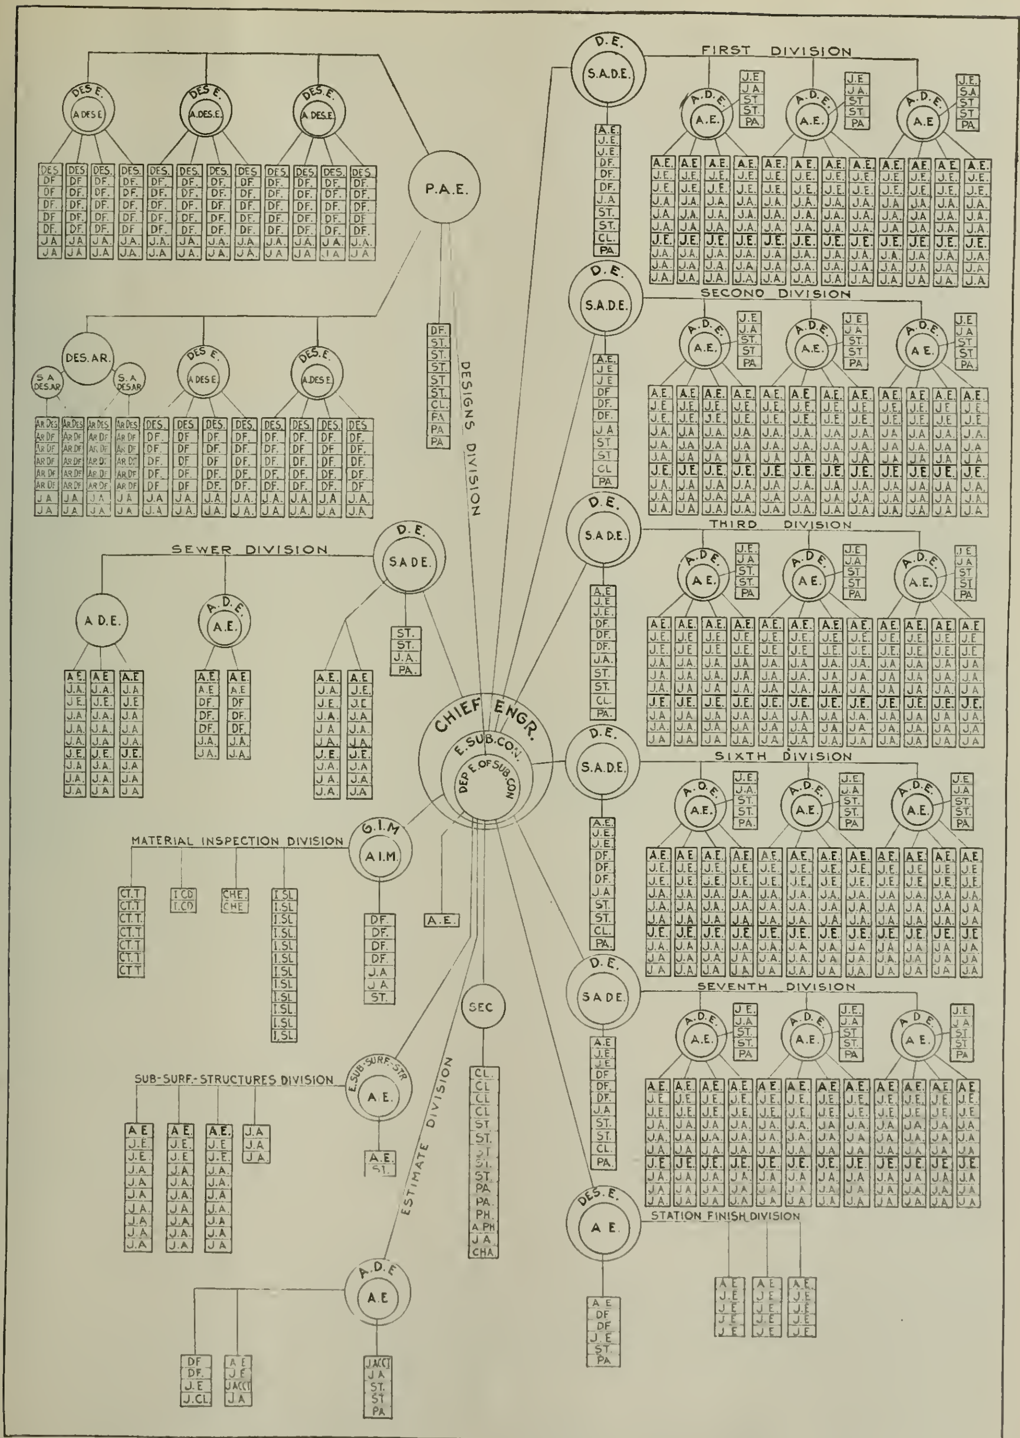
DEPUTY ENGINEER OF SUBWAY CONSTRUCTION—[illegible]

PRINCIPAL ASSISTANT ENGINEER—In charge of the Division of Designs. [illegible]

ABBREVIATIONS USED ON ORGANIZATION CHART ON OPPOSITE PAGE

Abbreviation	Title	Salary
[illegible]	[illegible]	[illegible]

[illegible]



Organization Chart of the Engineering Staff of the Public Service Commission

[illegible] plans [illegible] and also [illegible] for work [illegible] to the [illegible] companies.

DIVISION ENGINEER—In direct charge of a division of construction work in the field covering subway and elevated construction. Has charge of construction work amounting to from [illegible] to [illegible].

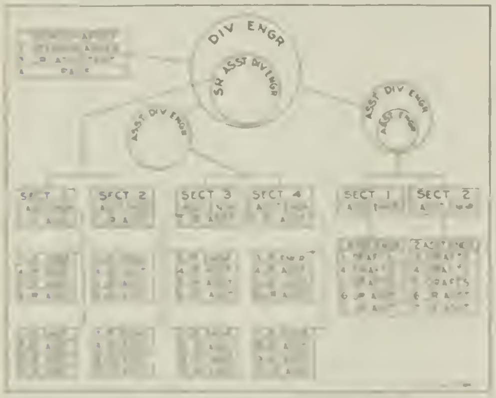
DIVISION ENGINEER OF SEWERS—In charge of Sewer [illegible] direct charge of the preparation of designs and plans and supervision in the field over all sewer reconstruction work resulting from subway or elevated construction.

ENGINEER OF SUBSURFACE STRUCTURES—In charge of the Division of Subsurface Structures. In direct charge of the preparation of all designs and plans covering the reconstruction and [illegible] of all sub-surface structure work in connection with the construction of subway and elevated lines.

GENERAL INSPECTOR OF MATERIAL—Has direct charge over the [illegible] of all materials of construction.

SENIOR ASSISTANT DIVISION ENGINEER—In charge of administrative work of a field division, under the Division Engineer. Acts as Division Engineer in the absence of Division Engineer.

ASSISTANT DIVISION ENGINEER—In direct charge of a subdivision of field work under the Division Engineer, consisting of four contract sections of subway or elevated construction covering work amounting to from $1[illegible] to [illegible].



[illegible]

[illegible]

ASSISTANT ENGINEER—In direct charge in the field of the details of construction of one contract section of subway or elevated work, under the Assistant Division Engineer, approximating $1,[illegible] to $[illegible] in cost.

JUNIOR ENGINEER—Has charge of the administrative work of a contract section or of a field party giving lines and grades, under Assistant Engineer.

DESIGNER—In charge of a squad of Draftsmen and Junior Assistants in computing and preparing designs and plans, under Assistant Designing Engineer.

DRAFTSMAN—Does detail work in preparing designs and plans, under Designer.

ARCHITECTURAL DESIGNER—In charge of a squad of Architectural Draftsmen and Junior Assistants in computing and preparing architectural designs and plans, under Assistant Designing Architect.

ARCHITECTURAL DRAFTSMAN—Does detail work in preparing architectural designs and plans, under Architectural Designer.

JUNIOR ASSISTANT—Acts as a member of field party giving lines and grades, under Junior Engineer, or does detail work on tracings, plans, etc., under Draftsman or Architectural Draftsman.

CHEMIST—Makes chemical analyses of materials under the General Inspector of Material.

CEMENT TESTER—Tests cements under the General Inspector of Material.

INSPECTOR OF STEEL—Inspects the manufacture and fabrication of steel at the mills and shops and the erection of the steel in the field, under the General Inspector of Material.

INSPECTOR OF CONDUITS—Inspects the manufacture of conduits, under the General Inspector of Material.

CHIEF CLERK—Secretary to Chief Engineer. Has direct supervision over Engineering Department general files and clerical and stenographic work in the general office, under the Deputy Engineer of Subway Construction.

ASSISTANT CHIEF CLERK—Has charge of filing and clerical work under Chief Clerk.

The lowest [illegible] grade is that of Junior Assistant, with an [illegible] salary of $[illegible], with [illegible] to $1,[illegible] [illegible] of rank. By passing the [illegible] examinations and fulfilling the [illegible], the Junior Assistant is eligible to the position of Junior Engineer at a salary of $[illegible] to $1,[illegible], or the [illegible] rank in the drafting-room force, and so on; so that a capable man is assured of reasonable progress as he [illegible]. The Junior Assistant corresponds to the rank of [illegible], [illegible], etc., in other city work, but is better paid.

DIVISION ORGANIZATION—Each field division is itself [illegible] as shown in the [illegible], p. [illegible], the organization chart for the sewer division [illegible] as an example to illustrate how the [illegible] is [illegible] out in [illegible] detail. There are at present [illegible] field Division Engineers, each with such a [illegible] independent organization [illegible]. Each field division [illegible] approximately $[illegible] to $[illegible] in work, the division being so [illegible] to [illegible] a [illegible] or a geographical district.

The field divisions are subdivided as follows: three subdivisions, each in direct charge of an Assistant Division Engineer; [illegible] four sections, each comprising a normal contract of from $[illegible] to $[illegible], each section being in charge of an Assistant Engineer. The sections, like the divisions and subdivisions, are groups of construction work of approximately the same character [illegible] rather than divisions of length. Each Assistant Engineer has, under the full [illegible], [illegible] Junior Engineer assistants, and the [illegible] Junior Engineers have [illegible] Junior Assistants, the lowest engineering grade on the staff. A section usually covers a distance of from [illegible] to [illegible] lin. ft. of trackway.

Besides the salaried engineering staff of each division, there are [illegible] and [illegible] inspectors of construction [illegible]

to each section, who are paid $4.50 to $5.50 per day, and who are not included in the organization scheme. The inspectors report to the Assistant Engineers in charge of their respective sections.

A similar scheme of subdivision exists in the office divisions of inspection of material, subsurface structures, station finish and estimates, and the divisions of design and of sewers. The various designers and draftsmen are divided into groups and squads in charge of Division Engineers, Assistant Division Engineers, Designers, etc., with ranks, grades and salaries corresponding to the field positions. Positions such as the one previously noted for Assistant Division Engineer are usually open to both field and office men, so it is possible for a man to be promoted from office to field, or *vice versa*.

Work of the Engineering Staff

It is almost impossible within a brief space to give an adequate idea of the breadth and scope of the engineering work the Public Service Commission's engineers are called upon to perform. The rapid-transit work alone requires careful surveys of the streets and subsurface structures, the examination of buildings before and during the construction of subways on account of the possibility of damages, the preparation of contract and detail plans, the examination of steel plans, the testing and inspection of materials such as cement and steel at the mills where they are manufactured, the close supervision of the construction work as it progresses, the preparation of the estimates upon which the payments to contractors are made, the redesign and construction of sewers and other subsurface structures, the passing upon all the equipment for the operation of the new railways, and other problems too numerous to mention. Besides these there are the disposition of complaints, the maintenance of existing subsurface structures and street traffic to be looked after during the period of construction.

The rapid-transit construction work has been outlined in 15 steps, as follows:

(1) Preliminary survey of streets to be traversed.
(2) Preparation of route maps and resolutions.
(3) Application to and approval by the Board of Estimate and the Mayor.
(4) Consent of property owners or of the Appellate Division.
(5) Survey of surface and subsurface structures.
(6) Preparation of contract plans.
(7) Preparation of form of contract.
(8) Public hearing on form of contract.
(9) Approval of form of contract by Corporation Counsel.
(10) Advertisement for and receipt of bids.
(11) Acceptance of bids and submission to Board of Estimate for approval and appropriation.
(12) Execution of contract and commencement of work.
(13) Preparation of working plans and examination of the working steel plans.
(14) Preparation of record plans.
(15) Arbitration of disputed items of cost.

The rapid-transit construction work cannot be compared with the work of any other commission in this country except the Boston Rapid Transit Commission, but it must be remembered that besides construction work, the Public Service Commission of the First District also performs the regulatory work of supervising all the public services of the Greater New York District, the transportation, gas and electric businesses of which amounts to about 20% of the total for the entire United States. The number of passengers carried annually on the existing transportation lines in the city is some 60% more than the number carried by all the steam railways of the country.

Electrical Engineer—The Electrical Engineer, Clifton W. Wilder, maintains a bureau, not shown on the organization chart, employing about 60 engineering assistants. His work is divided into four main divisions as follows: (1) Passing on all plans for the electrical equipment; (2) cost accounting of equipment; (3) supervision of operation of the existing lines; (4) valuation of public-utility corporation properties. On the first two divisions, as a part of the new subway construction, he reports to the Chief Engineer, but on the supervision of operation and valuation work he reports directly to the Public Service Commission as its Electrical Engineer. He has one Principal Assistant Engineer and six Assistant Engineers. The supervision of operation includes such work as investigating complaints of equipment, accidents, regular inspection of equipment, special investigations, etc.

Personnel

The scheme of an engineering organization plays only a small part in its successful operation. Much depends on the men who are at the head of it. The Chief Engineer of the Public Service Commission is himself the kind of man to appreciate the importance of personality in the efficient working of the splendid organization he has achieved; and he not only takes a kindly interest in his many subordinates and makes himself accessible to them, but has so designed the working of the entire organization as to promote individual effort, enthusiasm and loyalty.

Alfred Craven

The Chief Engineer of this great organization, which at present includes approximately 1000 engineering employees—and it is growing—is a descendant of a distinguished family of naval officers and engineers. He was the son of Rear-Admiral Thomas T. Craven, who served throughout the Civil War and was afterward Commandant of the Mare Island Navy Yard. He is a nephew of Alfred W. Craven, Chief Engineer of the old Croton Aqueduct, builder of much of the original sewer system of lower Manhattan, the Central Park Reservoir, and many other historic engineering works in and about New York City.

Alfred Craven was born at Bound Brook, N. J., Sept 16, 1846. At 17 years of age, at the height of the Civil War period, he was appointed to the United States Naval Academy, then conducted at Newport, R. I. Later, after the coming of peace, the Academy returned to Annapolis, Md., where Mr. Craven was graduated in 1867. After a few years' service, and while on the Pacific Coast, he retired from the Navy with the rank of Master, to devote his life to engineering.

In 1871, he joined the California Geological Survey. Later, he was engaged in irrigation work in the Sacramento and San Joaquin Valleys, and then began private practice in Virginia City, where he established a reputation as a mining engineer in connection with the development of the famous Comstock lode. On this work he was associated with Adolph Sutro in the construction of the well known Sutro tunnel.

Mr. Craven returned East in 1881 to become Division Engineer of the new Croton Aqueduct for the additional

water supply for the City of New York, where he was in charge of a construction division and later of the Croton and Titicus Dams and reservoirs. On this work he established an enviable reputation for rugged honesty in the midst of graft and corruption on the part of contractors and politicians. After some straightforward and uncompromising testimony before a legislative committee, an incensed politician is said to have told Mr. Craven, "You've done the last stroke of work you ever will do on this job." Whereat, Mr. Craven is said to have quietly replied, "I'll be here when you're all gone!"—which proved correct, for the Aqueduct Commission was subsequently reorganized by Mayor Hewitt, and men of a

St. and Park Ave. through Forty-second St. and up Broadway to 104th St., the section through Forty-second St. and under the Times Building being one of the most difficult and delicate pieces of the whole work. He succeeded George S. Rice as Deputy Chief Engineer of the Rapid Transit Commission in 1904, when Mr. Rice became Chief Engineer, and succeeded to the office of Deputy Engineer of Subway Construction under Mr. Rice, when the Public Service Commission was organized in 1907. In 1910, Mr. Craven succeeded H. B. Seaman as Chief Engineer of the Commission.

Mr. Craven has not only distinguished himself in his 44 years of varied experience as a great engineer and

D. L. Turner Alfred Craven Robt. Ridgway

[illegible]

[illegible]

[illegible]

Robert Ridgway

[illegible]

Brooklyn and on a New Jersey farm until he was 19 years of age. He never attended a college or technical school.

In May, 1882, he went West and joined the engineer corps of the Northern Pacific Ry., serving as chainman, rodman and leveler on preliminary surveys in Montana, and on location and construction in Wisconsin. Mr. Ridgway returned to the East in the summer of 1884 to accept a position as a leveler with the Croton Aqueduct Commission, New York City.

For 16 years he was a member of the Commission's engineering staff. His first important assignment was as Assistant Engineer in charge of the construction of the gate-house and appurtenances at the Croton dam and the northerly 1½ miles of the new Croton Aqueduct, from 1886 to 1890. On the practical completion of this work he was made Assistant Engineer of Construction of Reservoir M and appurtenances, on the Titicus River, which included the construction of a masonry dam having a maximum height of 130 ft., with earth wings 100 ft. in height. Subsequently, he was Assistant Engineer in charge of the construction of the Jerome Park reservoir, serving there under his present chief, Mr. Craven, who was Division Engineer.

He followed his chief to the Rapid Transit Commission in 1900 as his Senior Assistant Engineer on the Second division. In March, 1903, Mr. Ridgway was promoted to be Division Engineer and was placed in charge of the Fifth division, including the construction of the South Ferry loop, the tunnels under the East River from the Battery to Brooklyn and the Brooklyn subway.

When the Board of Water Supply was organized in 1905 for the construction of an additional system for the water-supply of New York City, he joined the staff of its Chief Engineer, J. Waldo Smith, as Division Engineer, and was promoted the following spring to the position of Department Engineer in charge of the Northern Aqueduct Department, which included the location and construction of the upper 60 miles of the Catskill Aqueduct. The Hudson River crossing at Storm King mountain was in his department. Here he continued until the practical completion of most of the work under construction, in January, 1912, when he was again called to serve under his former chief, Mr. Craven, with the Public Service Commission.

Daniel Lawrence Turner

Daniel Lawrence Turner was born in 1869. He graduated from Rensselaer Polytechnic Institute with the degree of C. E. in 1891.

For a year he was assistant in mathematics at the Institute, and then for three years he was Assistant Engineer in charge of the location and construction of a standard-gage switchback railway near Middletown, Conn., for the Columbia Granite Co.

In 1893, he was engaged in railway location work and as Engineer for Ernest Flagg, Architect, New York City. For nine years following, Mr. Turner was Instructor in surveying, railway engineering and hydraulics at Harvard University. While at Harvard he inaugurated the Harvard engineering camp and established and conducted for a number of years the present camp at Squam Lake, N. H. During this period, he was also engaged in private practice with special reference to hydraulic engineering.

Mr. Turner, like his chief and Mr. Ridgway, is also a pioneer New York City subway engineer. His experience in this work dates from the beginning of the subway work in 1900 when he became a member of the engineering staff of the Rapid Transit Commission. During the life of the Rapid Transit Commission 1900-1907, he served in various capacities, first on the preparation of drainage plans, as Assistant Engineer in charge of stations and in charge of surveys for subway extension to Brooklyn, including the East River triangulation. Later he was Division Engineer in charge of stations.

Upon the establishment of the Public Service Commission, First District, in 1907, Mr. Turner became Division Engineer of Stations and Chief of the Bureau of Transit Inspection, in which latter position he originated and formulated the methods of supervising the operation of the various street railways coming under the Public Service Commission's jurisdiction. For a year he was Division Engineer of the Seventh division of the new subways, and since 1912 he has been Deputy Engineer of Subway Construction.

Division Engineers

Sverre Dahm, Principal Assistant Engineer in charge of the Division of Design, was born in Norway, in 1858. His technical education was received at the Polytechnicum, Munich, Bavaria. He began his engineering experience as an Assistant Engineer on the Norwegian Government railways. His first work in America was as Assistant Engineer for Theodore Cooper, Consulting Engineer, New York City. Subsequently he was in bridge and structural work with the Long Island R.R., and with contractors in Chicago and New York City, until June, 1900, when he was appointed Assistant Engineer of the Rapid Transit Commission. Since then he has passed through various grades in the Rapid Transit Commission and its successor, the Public Service Commission, and since 1909, has been Principal Assistant Engineer.

Frederick W. Carpenter, Division Engineer of construction, was born in 1859, and graduated from Cornell University in 1881. For 10 years he was in railway construction and municipal work in the East and Middle West. In 1895 he was appointed Assistant Engineer, Bureau of Highways, Brooklyn, N. Y., where he remained until 1900, when he became Assistant Engineer of the Rapid Transit Commission. He continued as Assistant Engineer of the Public Service Commission, and in 1910 was promoted to be Senior Assistant Division Engineer, and Division Engineer in 1913.

John H. Myers, Division Engineer of construction, was born in 1869 and graduated from Rensselaer Polytechnic Institute in 1893. After a few years' experience in general surveying and engineering work in and about New York City, he spent six years as Assistant Engineer with the Department of Water Supply of Brooklyn, N. Y. In 1900 he joined the engineering staff of the Rapid Transit Commission as Assistant Engineer, and in 1906 he was promoted to be Division Engineer, which office he continued to hold under the Public Service Commission.

Frederick C. Noble, Division Engineer of construction, is a son of the late Alfred Noble. He was born in 1872 and graduated in civil engineering at the University of Michigan in 1894. Most of his experience until 1900 was in bridge and structural work. He

[illegible] the service of the Rapid Transit Commission as [illegible] from 1901 to June, 1900. He was promoted to be Assistant Engineer the following summer and to be Division Engineer in 1905. Mr. Noble has had immediate supervision of the design and preparation of contracts and specifications for the four East River tunnels for which contracts have recently been awarded.*

[illegible] A. Pierce, Division Engineer of construction, was born in 1860. He is a graduate of the [illegible] University School of Mines and his first experience was as Chemist and Metallurgist for a smelting company. His civil engineering experience began as a laborer with the New Croton Aqueduct Commission in 1885. He was successively promoted through subordinate positions to be Assistant Engineer. In 1900 he joined the staff of the Rapid Transit Commission as Assistant Engineer. He was promoted to be Division Engineer in 1903.

Jesse O. [illegible], Division Engineer of construction, was born in 1868. He graduated from Bucknell University, Pennsylvania, in 1890. The first 10 years of his engineering experience were spent mostly in railway survey and construction work. In June, 1900, he was appointed transitman with the Rapid Transit Commission and a year later Assistant Engineer. In April, 1910, he was promoted to be Senior Assistant Division Engineer and in October, 1911, Division Engineer.

[illegible] D. [illegible], Division Engineer of Sewers, was born in 1867. He was in railway work in the East. From 1901 to 1908, he was Assistant Engineer of the New York, New Haven & Hartford R.R., and had charge of construction of two large Scherzer rolling lift draw bridges, one four-track and the other six-track. He joined the staff of the Public Service Commission in 1908 as Division Engineer.

The Division Engineer in charge of Subsurface Structures is C. N. Green, and George L. Lucas is Division Engineer in charge of Inspection of Materials and Construction.

ELECTRICAL ENGINEER

The Electrical Engineer of the Public Service Commission, Clifford W. Wilder, was born in Leominster, Mass., in 1876, and graduated from the Massachusetts Institute of Technology in 1898. For several years he was engaged in various kinds of electrical and mechanical engineering in and about Boston and New York City. He first became connected with New York City electric railway work in April 1903, as Assistant Engineer of Construction with the New York City Interborough Railway Co. He joined the staff of the Public Service Commission in November, 1907, as Assistant Electrical Engineer, becoming the head of the department in 1909. This position requires not only wide technical knowledge and experience in electrical engineering, but also the ability to appear as an advocate and expert at public hearings of the Commission.

*[illegible]

::

Train-Stops On the Chicago & Eastern Illinois R.R.

While automatic train stops as auxiliary to block signals are in extensive use on electric, elevated and underground railways, we believe the Chicago & Eastern Illinois R.R. is the only surface steam railway in this country which has a train-stop system in regular use. The system is the invention of H. B. Miller, of Staunton, Va., and for information concerning its use we are indebted to L. C. Hartley, Chief Engineer of the Chicago & Eastern Illinois R.R.

The equipment is on a stretch of double-track line between Hoopeston and Danville, Ill., 24 miles, having 35 blocks (with automatic block signals), each block equipped with the track-contact device for the train-stop. About 90 locomotives in passenger and freight service are equipped with the contact shoe and brake-control apparatus. The traffic is from 18 to 20 trains daily on each track, but not all the locomotives on these runs are equipped with the train-stop apparatus. It is expected to extend the equipment north from Hoopeston to Dolton, an additional 82 miles of double track. The apparatus has been installed also on 20 miles of double track between Findley and Arthur (10 miles of automatic block signals and 10 miles of manual block), but this is not yet in service.

The track contact is a T-bar 180 ft. long, placed outside of the track, 22 in. from the rail, as shown in Fig. 1. It has a maximum height of 5 in. above the rail, and the ends are inclined, the contact shoe on the engine engaging the contact bar or ramp at about 3 in. above the rail. The contact apparatus on the engine, shown in Fig. 2,

FIG. 1. TRACK CONTACT DEVICE FOR THE MILLER TRAIN-STOP SYSTEM, CHICAGO & EASTERN ILLINOIS R.R.

consists of a shoe on a vertically sliding bar; this is raised when it engages the track device and its movement makes the necessary electrical connections to apply the air brakes and to close the throttle. The ramp or track contact is placed at such a distance from the signal as to enable a train to be stopped before reaching the signal; this distance varies with local conditions, but averages about 1500 ft.

The equipment was installed for a service test under regular traffic, and has been in use for about nine months. This included a part of the winter, but the apparatus worked successfully in spite of snow and sleet storms. We are informed that on different occasions its operation has stopped regular trains running at various speeds. As a matter of record of the test, each engineman (on the equipped engines) marks on a report card the position of each signal on the 24-mile stretch of track so governed.

The apparatus complies with the requirements of the American Railway Association, except that it will not correct the signal indication providing the track relay is held up, with block occupied. It is not equipped with the speed-control feature specified in the above requirements, but it is possible to add this when desired. There is no cab signal, either audible or visual, and no indication is given on the engine when passing a "clear" signal.

The following description is an abstract of an article in the *Signal Engineer*, by H. H. Orr, Chief Signal Inspector of the Chicago & Eastern Illinois Ry.

The train control is installed as an adjunct to the automatic block signals, and operated through the track relay and circuit controller. The first engines to be equipped were those used in the local freight service. It was thought that if there were any defects in the system they would develop on these runs, as here the most complicated conditions are met with. Many tests have been made on trains of various lengths with loaded and empty cars, and in each case the control has been effective in applying the air-brakes and closing the throttle simultaneously, making a smooth stop without unnecessary shock to the equipment of the engine or train.

The principle of the system is as follows: A stationary ramp, placed beside the track at braking distance back of each automatic signal (or the block station), is in the path of a contact shoe on the engine. This shoe, as it travels over the ramp, is raised vertically. If the block about to be entered is unoccupied and the signal ahead indicates "proceed," the vertical lift of the shoe does not affect the operation of the train. If the block ahead is occupied or the governing signal indicates "stop," this vertical lift of the shoe closes the throttle and applies the air-brakes, bringing the train to a stop.

The engine equipment consists of the control mechanism placed in a small steel box in the cab; the contact shoe, carried by a bracket on the crosshead guide, and air cylinders and connections for transmitting the motion of the shoe to the throttle and brake valve through the control mechanism. The track equipment consists of the ramp, a relay and battery located at the ramp, and a circuit controller at the signal ahead. The control mechanism is, in effect, a bell crank whose two arms are locked rigidly with respect to each other by the plunger of an electro-magnet normally deënergized. The upward motion of the shoe is transmitted to one arm of this crank through an air cylinder. The other arm of the crank is connected through an air cylinder to the throttle and brake valve. When the control magnet is energized, the crank arms are disengaged, thereby breaking the connection between the engine shoe and the brake valve.

Energy for operating the control magnet is supplied by a battery located at the ramp and so connected through the track relay and automatic signal that when the block about to be entered is unoccupied and the signal indicates "proceed," the battery is connected, one terminal to the facing end of the ramp and the other to the adjacent running rail. Under these conditions, the control will be energized the instant the engine shoe engages the ramp, and the train will pass over the ramp without interruption. When the block ahead is occupied or the governing signal indicates "stop," the battery is disconnected from the ramp; the control magnet of the engine passing over it will receive no current and the brakes will be applied and the throttle closed.

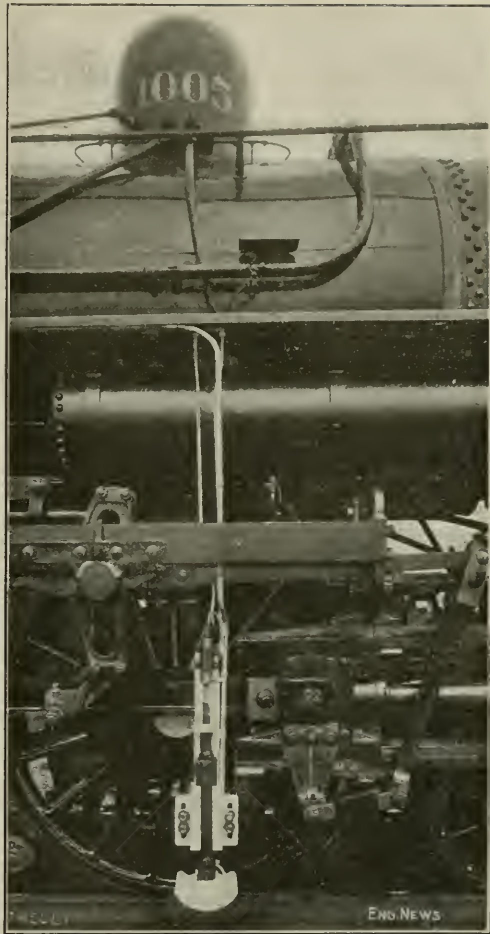


Fig. 2. Contact Shoe of Train-Stop System on a Locomotive of the Chicago & Eastern Illinois R.R.

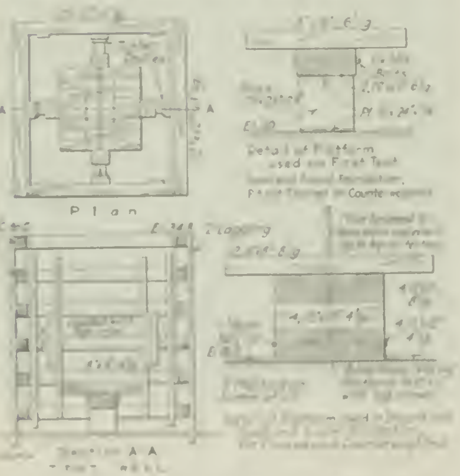
The ramp is divided by two insulated joints in the middle, the trailing end being supplied with energy for the purpose of energizing the control and preventing stop of an engine making a back-up move. As now applied, the breaks may be released and the throttle opened by the engineman in the usual way, at any time after being operated by the automatic-control system. This has proved satisfactory, but if thought desirable, a speedometer may be so locked as to necessitate the full stop of a train and release from the ground by the engineman. Due to the simplicity of the apparatus and its similarity to other signal and engine equipment, the maintenance can be cared for by the men employed in the maintenance of the signal and mechanical departments.

The records of this service show instances of "safety failure" or unnecessary stops due in general to such causes as commonly affect automatic signal operation, but in no case has the control failed to bring the train to a stop with the block ahead already occupied or the signal at "stop" position.

Field and Office

Soil-Bearing Tests for New Railroad Building, St. Paul, Minn.

Tests of material beneath ground filled in about 10 yr. ago in St. Paul were recently carried out to determine the feasibility of its holding up a new 12-story office building under a load of 4 tons per sq.ft. The structure is being erected on a [illegible] space at Jackson and Sibley Sts. between Fourth and Fifth Sts., jointly by the Northern Pacific Ry. Co., the Great Northern Ry. and the First National Bank. Considerable doubt was felt as to the bearing value of the material under the filled area on the Fourth St. side, so that tests up to 8 tons per sq.ft. were initiated. The material under the footings, about 15 ft. below the surface, was a mixture of



Test Arrangement for Soil-Bearing Tests at Railroad Building, St. Paul

coarse sand and comparatively small gravel with about [illegible] of clay. Possibly [illegible] of gravel would not pass a [illegible] ring but the remainder was graded down to fine gravel.

Tests were carried out in [illegible] excavated [illegible] down to the [illegible] elevation of the footing, the pit being sheet-piled [illegible].

First Test—The bottom of the pit was leveled and a block [illegible] square placed on the [illegible] with a [illegible] pipe extended to the top of the pit to provide a hand [illegible]. The [illegible] was loaded [illegible]. [illegible] The [illegible] are given in Table I.

Second Test—A second test was then carried out with a block 4 ft. square, the remainder of the pit being cov-

	Total settlement	[illegible]

ered with 2-in. planks counterweighted to 175 lb. per sq. ft. to meet as nearly as possible the actual conditions that would exist were the building completed. To obviate any danger of the pig iron shifting or tipping over, planks were placed on the four sides of the load and the timber dollies attached to the sides of the pit, leaving ½-in. clearance.

But ¼-in. total settlement was noted (Table II), which was considered due to the block reaching its proper bearing. Inspection of the material under the block after the test showed no indication of displacements. A ½-in. layer of cement which had been placed to level the block was cracked only in a few places.

TABLE II. TEST WITH 4-FT. BLOCK. PIT FLOORED AND COUNTER-WEIGHTED

Time 1914	Load, tons per sq.ft.	Settlement, in.
May [illegible] p.m.	No load	[illegible]
May [illegible] p.m.	1	[illegible]
June 1, 7:00 a.m.	2	[illegible]
June 2, 8:00 a.m.	4	[illegible]
June 3, 7:00 a.m.	4	[illegible]
June 4, 8:00 a.m.	6	0
June 5, 7:30 a.m.	6	[illegible]
June 6, 7:00 a.m.	8	[illegible]
	Total settlement	[illegible]

Third Test—A test similar to the second one was repeated on the opposite side of the building site, where the material was all clean coarse sand. A total settlement of ½ in. occurred during the first part of the loading, the later readings up to 8 tons per sq.ft. showing no further settlement.

The tests were carried out under the direction of E. B. [illegible], Superintendent of Construction. Grant Smith & Co. are contractors for the Railroad Building. Chas. A. Frost is the Architect.

Three Short-Cuts in Surveyors' Computations

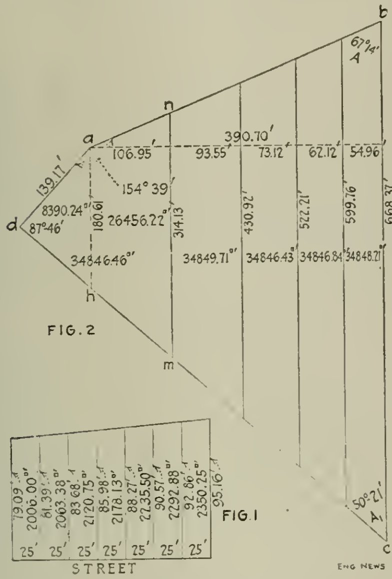
By P. H. [illegible]*

1. In computations such as those affecting suburban property, where an error of 0.02 or 0.01 ft. is in itself unobjectionable, the margin of accuracy may be converted into time saved, by a very simple process.

A case that arises frequently is that shown in Fig. 1, where the rear line is a number of adjacent lots of equal frontage F taken at oblique angle A with the street. If [illegible] the lengths of the first and last side lines are known or may be computed. The intermediate lot lines may be determined by adding a [illegible] successively to the smaller lot line, checking on the last lot line. But as [illegible] may not be expressed exactly in hundredths and as the lot lines are given to the nearest 0.01 ft., it fol-

*[illegible], Washington, D. C.

lows that there can be no common difference in length for all the lots, the difference between any two successive lot lines possibly varying by 0.01 from the difference immediately preceding or following. Hence it is necessary to compute the area of each lot separately, since an error of 0.01 in the length of the lot line makes an error of 0.005 a in area—a discrepancy easily detected, and giv-



ing an appearance of inaccuracy. If, however, the areas of the lots could be obtained by adding a common difference, checking exactly with lot lengths also obtained by adding a common difference, much time could be saved. This may be accomplished as follows:

Dividing the difference between the two outer lot lines, in this case 16.08, by the number of equal lots, 7, and carrying the result out to the nearest 0.005, we obtain 2.295, which we multiply by the number of lots, 7, giving 16.065, which we express to the next higher 0.01, giving 16.07. This we add to the smaller lot line, 79.09, giving 95.16. *The larger lot line is changed,* then, from 95.17 to 95.16, and the common difference for the lot lengths is 2.295, which we add successively to the smaller lot line, expressing the result always to the nearest higher hundredth.

When the above procedure calls for a difference of 0.02 between adopted length and actual length of the last side line, we may reduce one of the outer lines by 0.01 and increase the other by 0.01; that is, the change is to be divided as nearly equally as possible between the two outer lines.

The common difference of the areas is evidently the common difference of the lot lines, 2.295, multiplied by the lot width, 25, or 57.375. This difference we add successively to the area of the smaller lot, 2006, checking on the area of the larger lot, 2350.25.

Equal Lots in an Irregular Tract

2. A computation that sometimes arises for which a simple formula is desirable, is that shown in Fig. 2—where a trapezium or other irregular rectilinear figure is to be divided into a given number of lots of equal area by lines of a given direction. The first step is, of course, to determine the area of the entire figure $abcd$ = 174,240, which we divide by the number of lots required, 5, giving 34,848 as the common area of the resulting lots. Where the direction of the required lot lines is not parallel to an exterior line of the figure ad, the next step is to drop a line ah, of the required direction, to intersect cd, and determine the area of the figure adh, 8390.24, which we subtract from the common area 34,848, giving 26,457.76 as the area of the trapezoid $ahmn$.

To determine the width of $ahmn$, we have the formula

$$mn = \sqrt{(ah)^2 \pm 2F(\cot A \pm \cot A_1)}$$

where F = the area required, 26,457.76. Care must be taken to use the correct algebraic signs: if the angles A and A_1 are in the same quadrant we take the sum of $\cot A$ and $\cot A_1$; if in different quadrants, we take their difference; and the term containing this sum or difference is added to $(ah)^2$ when the lines bc and cd diverge toward mn, that is, when $A + A_1$ is less than 180°, and subtracted when greater.

Having obtained the length mn, we may either divide $mn - ah$ by $\cot A \pm \cot A_1$ to determine the width of the trapezoid, or we divide the area 26,457.76, by ½ $(ah + mn)$. The latter gives a greater degree of accuracy. As the lot depths are given only to the nearest hundredth, the areas computed from these depths will not quite tally with the required areas.

To obtain the lengths of the following lot lines, we add successively to $(mn)^2$, or 98,680.77, the amount $2F(\cot A \pm \cot A_1)$, or 87,009.88, giving 185,690.65, 272,700.53, etc. The square roots of these sums are the lengths of the lot lines required. The widths may be obtained by either of the methods described above. We may check the work by adding the width of each lot multiplied by $(\cot A \pm \cot A_1)$ successively to mn.

Saving a Line in Solving Triangles

3. Where a large number of right triangles is to be worked out by logs, as for instance in obtaining the coordinates for a traverse, we may effect a noticeable saving of time by writing the log of the course between log sin bearing and log cos bearing, posting the sum of log course and log sin bearing above, and the sum of the log course and log cos bearing below, thus:

(1)	log	242.51	= 2.3847367
(2)		sin 22° 19′ 30″	= 9.5796234
(3)		638.13	= 2.8051133
(4)		cos	= 9.9661624
(5)		590.58	= 2.7712757

Here line (1) is the sum of (2) and (3), and (5) is the sum of (3) and (4). Only five lines are written, as against the usual six, a saving of one line in six, or nearly 17% of the work of writing the quantities.

Similarly, where an oblique triangle is to be solved by the sine formula, we may write the work thus:

(1)	log	a	= 255.04	= 2.4066082
(2)		sin A	= 42° 11′	= 9.8270493
(3)		c	= 379.18	= 2.5788454
(4)	colog	sin C	= 93° 17′	= 0.0007135
(5)		sin B	= 44° 32′	= 9.8459188
(6)		b	= 266.37	= 2.4254777

Line (1) is the sum of (2), (3) and (4), and (6) is the sum of (3), (4) and (5); six lines are written, against the usual seven. With a little practice this may be done mechanically, with no increased chance of error, and without effort.

Converting a Pin-Connected Bridge into a Riveted Structure

The conversion of a pin-connected bridge span into a riveted span is an interesting and very exceptional piece of bridge work recently carried out. The bridge is a single-track swing span on a branch of the Pennsylvania Lines, crossing the Grand Calumet River, at [illegible], Ill., and was built by A. [illegible] & Co., in 1886. It is [illegible] ft. long, c. to c., having two [illegible]-ft. arms and a central [illegible]-ft. panel. It was necessary to adapt the bridge to carry heavy loading (Cooper's E-60), and investigation showed that this could be done more rapidly and at much less cost by strengthening the old structure than by replacing it by a new bridge.

Figs. 1 and 2 show the original design and the alterations, and Fig. 3 shows some details of the resulting riveted trusses. The work in general was as follows: (1) Reinforcing the main trusses; (2) adding an additional pair of stringers for each rail; (3) placing new top and bottom cover plates and additional end

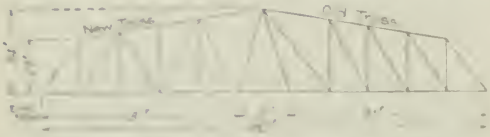


FIG. 1. DIAGRAM SHOWING DRAWBRIDGE WITH TRUSSES OF ORIGINAL PIN-CONNECTED TYPE AND AS ALTERED TO RIVETED TYPE

gusset plates on the floor-beams; (4) strengthening the circular girder of the turntable drum.

Trusses

The work on the trusses comprised the following changes (see Fig. 1): (1) Replacing posts B-b, C-c and E-e by new members. (2) Replacing the stiff web members b-C and c-D by new stiff members b-C and C-d. (3) replacing tension web members d-E and e-F by new stiff members d-F and E-f. (4) cutting the battens and lacing bars from the channels forming post D-d, shifting the channels inward (to clear the new gusset plates) and applying new battens and lacing bars; (5) applying new top cover plate and two new bottom flange angles to the end posts a-B. The old web members c-D and e-F are eliminated, and f-F has new battens at the bottom while the flanges of its channels are trimmed to clear the gusset plates.

In the bottom chord, gusset plates were applied for new riveted connections to the end posts and web members, new holes being drilled as required and battens removed where necessary to clear the gusset plates. The gusset plates at d were trimmed to clear the pin plates, and those at f were trimmed to clear rivets. In the top chord, similar work was done. The composition of the members is shown in the accompanying table.

MAKE-UP OF TRUSS MEMBERS OF BRIDGE CONVERTED FROM PIN-CONNECTED TO RIVETED. PENNSYLVANIA LINES

Member		Original	Altered
Bottom chord	a to c	2 channels, 10 in., [illegible] lb.	[illegible]
	c to f	2 channels, 1[illegible] in., [illegible] lb. 2 plates, 9x[illegible] in.	[illegible]
	f to [illegible]	2 channels, 1[illegible] in., [illegible] lb.	[illegible]
Top chord	B to F	2 channels, 1[illegible] in., [illegible] lb.	[illegible]
Verticals	B-b	2 channels, 8 in., 13 lb., removed	4 L's, [illegible]
	C-c	2 channels, 7 in., [illegible] lb. (removed)	4 L's, [illegible]
	D-d	2 channels, 9 in., [illegible] lb. (retained)	Channels moved over
	E-e	2 channels, 10 in., [illegible] lb. (removed)	4 L's, [illegible]
End Posts	a-B	2 channels, 1[illegible] in., 73 lb.	1 plate, 1[illegible] in. 2 L's, 3[illegible] in.
Diagonals	b-C	2 channels, 7 in., [illegible] lb., removed	4 L's, 3[illegible] in. 2 plates, 1[illegible] in.
	C-d	(In place of c-D removed)	4 L's, 3[illegible] in. 2 plates, 1[illegible] in.
	d-F	2 [illegible] bars, removed	4 L's, [illegible] in. 2 plates, 1[illegible] in.
"	E-f	(In place of e-F removed)	4 L's, [illegible] in. 2 plates, 1[illegible] in.
"	f-F	2 channels, 1[illegible] in., 112 lb.	Flanges trimmed, new battens

Erection Work

Under the railway company's instructions, the first work was confined to the half of the bridge west of the pivot, and this was completed before beginning work on the other half of the bridge. The blocking and shoring used are shown in Fig. 2.

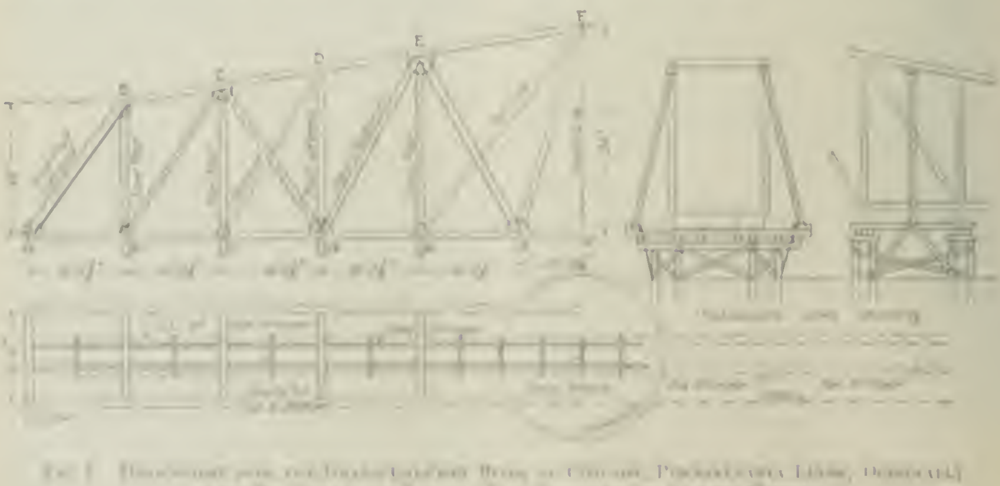

FIG. 2. [illegible] WITH PIN-CONNECTED TRUSSES, NOW CONVERTED TO RIVETED TRUSSES

(The heavy lines show the new work)

It was required that all floor-beams must have full bearing on the pile bents before any truss members were disturbed. For the half of the bridge on which work was done the top-chord members of both trusses were supported at the center of each panel by shoring timbers, as shown. And in the other half of the bridge, opposite that which was being prepared for reinforcement, the member *d-E* was stiffened by fitting a 6x12-in. timber (in one piece) between the eye-bars, and fastening it to these bars, its ends bearing against oak blocks fitted and secured at the top and bottom panel points.

The bridge being thus supported on falsework, all members to be removed were cut away; this included the batten plates and lacing bars on *d-D*, the pins, floor-beam hangers, etc., except that the temporary removal of battens and lacing bars on *f-F* was deferred until it became necessary. In the top and bottom chords, the batten plates and lacing bars were cut away where necessary to admit of placing the new truss members. No drilling of holes between the gusset plates and the webs of top or plates on the outside of the chords. In riveting diagonal *b-C* to the gussets at *b*, the post *b-B* had to be swung clear at the bottom, after which the post was replaced in position, with the hanger *FB*-1 and the pin replaced at *b*.

The final riveting of the new members in place was then proceeded with. It was necessary to draw the channels of old member *d-D* first to one side and then to the other in order to allow of driving rivets through the diagonal and gusset plates at *d*. The same had to be done with old member *f-F* for the riveting at *f*, but with special care, as this member might take stress when trains were crossing the bridge. Care had to be used in making the splice near the end of the bottom chord, so as to obtain the proper panel length, as shown on the drawings.

Other Work

Stringers—For placing the additional line of stringers under each rail, holes were drilled in the floor-beams for the end connections, using the filler plates as templates. Holes were cut in the webs for the bottom lateral

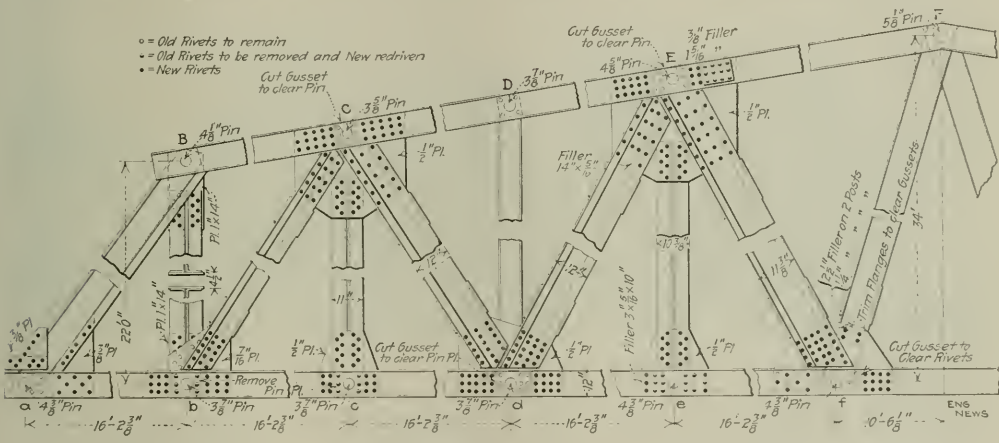

Fig. 3. Details of Truss as Converted from Pin-Connected to Riveted Truss

bottom chords was permitted until all new members were assembled and field-bolted in position.

The placing of new members was specified to be done in the following order: Diagonal *E-f* must be swung over the old member *f-F* in such a manner that the gusset plates at *E* could be put in position, and also so that the post *e-E* might be placed in approximate position, but with its upper part against the diagonal *E-f*, so as to permit of swinging the diagonal *d-E* in place after the gusset plates at *d* were in position. Then the post *e-E* was set, followed in the order named by the gussets *f*, diagonal *E-f*, gussets *C*, diagonal *C-d*, post *C-c*, gussets *b*, and diagonal *b-C*.

Then the new floor-beam pin plates were placed in position at points *c*, *d* and *e*, and the pins at these points were replaced. The work on the end post was allowed to be done at any convenient time, except that the reinforcement of its bottom flange was required to be riveted up completely before placing the post *b B* in position. This post being placed in position temporarily, all members were then bolted together and holes drilled through the webs of the top and bottom chords to correspond with the holes in the gusset plates, using templates. rods, these rods being removed and replaced by passing them through the stringers. Before riveting the new stringers in place, all the filler plates, diaphragms, cross-frames, struts and lateral rods were fitted into place.

Floor-Beams—The new cover plates had $\frac{3}{4}$-in. punched holes reamed to $\frac{15}{16}$ in., and these plates were used as templates for drilling the old flange angles (in place). Before riveting up these plates all parts were adjusted to position; these included the stringers, operating-rod castings on intermediate floor-beams, rail-joint castings, diaphragms, and the stiffener angles on the end floor-beams.

The new hanger plates on the ends of the floor-beams being set in place, the old ones were replaced outside of them. The two plates were fastened together by the top five rivets (with flattened heads) before being put in final position. The new plates had been punched with $\frac{7}{8}$-in. rivet holes and bored to fit the pins. The holes in the new and old plates and end angles were reamed to $1\frac{1}{16}$ in. in the field, for new 1-in. rivets. The truss pins were removed and replaced as part of the operation.

Drum Girder—The new top and bottom cover plates were added in the same way as described for the floor-

ceeded. New inclined stiffeners were run from the struts [illegible] to the center support.

CLEANING AND PAINTING.—Where the old metal would be [illegible] inaccessible by the application of the new parts, the old surface was cleaned and given a coat of paint. All new metal was given a shop coat, and its contact surfaces were given an additional coat before assembling. After the completion of the work, all the metal was cleaned and given two coats of paint.

ERECTION OF WORK.—One arm of the bridge is over shallow water and the other over the navigable channel. The plan of reconstruction adopted was to build falsework under the former arm and make all the alterations to it, each truss part being removed from it as was necessary to make way for the new parts. The bridge was then reversed, and the other arm treated in the same way. This falsework (which was built by the contractors) is shown in Fig. 2. The traffic averaged 20 trains daily.

As the work was done before the navigation season opened, the bridge was not required to be swung for river traffic. When reversed for the reconstruction work, it was swung by means of its hand-operated machinery in the regular manner. A locomotive crane standing on the bridge was used to take out the old members and put the new members in place, while the use of oxyacetylene torches in cutting away old rivets considerably reduced the time and cost of the work.

In all, about 29 tons of metal were removed and 80 tons of new metal placed, the bridge as now completed having a weight of about 170 tons.

The necessary alterations to the bridge and the methods of carrying them out were planned under the direction of J. C. Bland, Engineer of Bridges of the Pennsylvania Lines. The contract for the erection of the work was awarded Dec. 2, 1913, to the Great Lakes Dredge & Dock Co., of Chicago. This company also furnished detail and shop drawings for the approval of the railway engineers. Work was commenced Jan. 23, 1914, and completed Mar. 17, 1914. The cost was approximately $18,500, while it is estimated that a new bridge to meet the same conditions would have cost about $75,000.

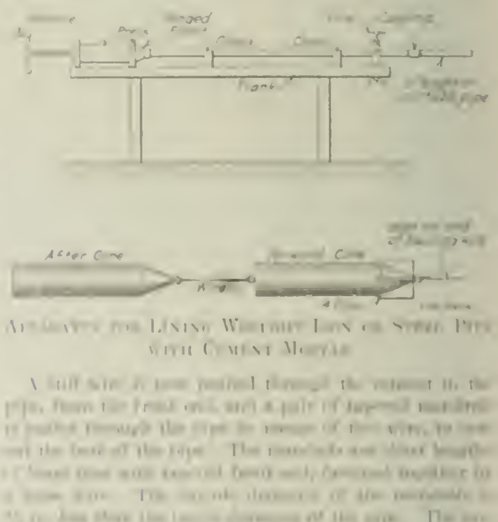
It is of interest to note that the Pennsylvania Lines strengthened the draw span over the Maumee River, at Toledo, in a similar manner in 1903, this being a span 182 ft. 9 in. long. Not long after the work was completed, the bridge was considerably damaged by a collision from a boat, but had the original unreconstructed structure still been in place, no doubt it would have been damaged much more seriously. The bridge was then repaired and carried traffic in good shape until recently when it was taken out of service.

Form-Spacer Bolt with Adjustable Head—[illegible]

Lining Pipe with Cement

Cement-lined wrought-iron service pipes, because of their freedom from interior corrosion and stoppage, have been used in New England and probably to a lesser extent elsewhere for many years. As a rule, it appears that each water-works department lines its own pipe. Recently, a company has been organized in Boston* to line pipe on order, either taking pipe supplied to it or furnishing the pipe itself. The procedure in lining the pipe is as follows:

A screw-piston press 5 in. in diameter and about 18 in. long, mounted on one end of an 18-ft. plank, is used to force the mortar into the pipe. The forward head of the press cylinder is hinged to swing open; it has a central hole threaded for 2-in. pipe (other sizes are accommodated by use of bushings). The cylinder head is swung open, the cylinder filled with mortar, and the head closed and locked. The pipe to be lined is then screwed into the hole in the cylinder head. By forcing the piston ahead, the cement is then shoved out into the pipe. After this the pipe is unscrewed and moved ahead onto a vise at the front end of the plank. A coupling is set up on the forward end, with a portable length of pipe about 15 in. long screwed into it as far as another pipe would be fitted, usually about six threads; this keeps the threads clear of mortar for connecting the length of pipe to another length.



APPARATUS FOR LINING WROUGHT IRON OR STEEL PIPE WITH CEMENT MORTAR

A stiff wire is now pushed through the cement in the pipe, from the front end, and a pair of tapered mandrels is pulled through the pipe by means of the wire, to form out the bore of the pipe. The mandrels are short lengths of [illegible] with tapered [illegible] ends, fastened together by a short wire. The outside diameter of the mandrels is ½ in. less than the inside diameter of the pipe. The forward mandrel has four longitudinal fins at 90 deg. intervals to center it in the pipe, while the rear mandrel is smooth and, following through the bore made by the first mandrel, finishes it to shape and surface. The result is a smooth ¼-in. lining of cement mortar. After [illegible] the pipe is laid away for the mortar to harden. The short length of pipe at the front is unscrewed and the coupling is left on.

All tees, elbows and other fittings are also lined with cement mortar, so applied as to give an interior surface continuous with that of the lined pipe and having [illegible] [illegible] to the flow.

*[illegible] Cement Lined Pipe Co., [illegible], Boston, Mass.

Emergency Work in Drainage-Ditch Excavation

The contractor on the construction of the Storm Creek ditch in Carroll County, Iowa, met with the misfortune of losing his 3-yd. oil-power dredge by fire when the work was 93% completed, and had to find some way of doing the remaining work quickly and economically.

The contract amounted to 2,300,000 cu.yd., the main ditch being about 25 miles long. The laterals and all small work were completed, and when the large dredge was burned there was 8400 ft. of the main ditch to be dug, crossing the old channel at several points. This was a difficult proposition: The amount involved was only about $8500, and as the work was nine miles from a railway (at Glidden), it was a problem to get out a machine that could be handled within reasonable cost. It was estimated that to do the work by an ordinary large dredge would cost $20,000. Contractors owning dragline machines were invited to submit proposals but the conditions were too severe for them to bid. The contract prices on this part of the work were $5\frac{1}{4}$ and 7c. per yd., with no deductions made for the old channel. The specifications required a ditch of 35-ft. bottom width, 8 to 12 ft. deep, with 1 : 1 slopes.

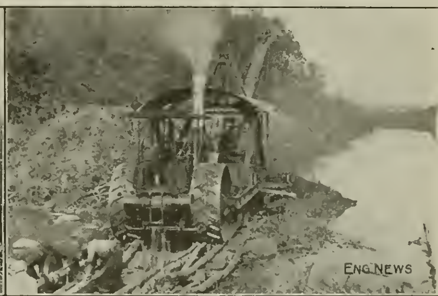
The features required in a machine to do the work within reasonable cost were quick delivery, low cost of transporting nine miles over land and installing on the work, low fuel consumption and small payroll expense. To meet the conditions, the contractor purchased a Turner dragline excavator, built by the United Iron Works Co., of Springfield, Mo. The machine was set up at the railway station, and traveled under its own power and on its own wheels to the work, making several turns at corners, and crossing two highway bridges. It required two days to move nine miles and cross the fields to the work. The machine has a steel frame, a 40-ft. boom and a $1\frac{1}{2}$-yd. scraper bucket. It is driven by a 60-hp. oil tractor, the front wheels of the tractor being removed, and the front end of its frame resting on a cross-beam of the dragline machinery frame. The extending side beams connect to an extension hub that is bolted to the driving wheel of the tractor. These removable hubs and the addition of a spur wheel on the main engine shaft were the only changes made to the tractor. The power is conveyed from the engine shaft to pinion shaft of the dragline machinery through a sprocket chain. The machine can handle two scraper loads per minute.

On account of the wide ditch and amount of material to handle, the machine was operated double cutting, with material cast on both sides. Fig. 2 shows the machine finishing a cut, and shows the approximate width taken at each cut. It shows also the method of crossing the old channel, brush and logs being laid in the creek bed, with poles on top to form runways for the wheels.

The machine started June 27, 1914. The first 18 days' work cost for labor $322.62, including one extra man dynamiting a ditch through a short cut. Fuel cost, $3 per 10-hr. work, being for 60 gal. of distillate. The 18 days', or 360 hours', work amounted to 42,913 cu.yd.

A considerable amount of work on the old channel figured in this estimate, but the machine met the conditions of moving from one cut to another and maneuvering to handle the material and open up into the old channel; such items being delays against actual digging. Part of the work is through heavy timber, and the banks were generally high and entirely of earth, although at the lower end of the stream there was good gravel bottom. For the crossings, places were selected where the material could be handled to the best advantage, and in going from one cut to another the machine would travel out around the bends or be moved to a place where a crossing could be put in to get across the old channel. It has excavated as high as 100 cu.yd. per hour, but the average seems to be about 65 or 70 yd. as there was so much maneuvering at the end of the cuts where the machine came up against the old channel.

A Combined Dragline Excavator and Oil-Engine Tractor for Ditch Work



Ditch Excavated by Oil-Engine Dragline Excavator

(The machine is shown crossing one of the numerous bends of the old channel intersected by the ditch.)

On the cut which the machine is shown finishing, in Fig. 2, the work included 15 hours making bridge and crossing it, 133 hours making the complete cut, 8772 cu. yd. actual cutting, or 66 cu.yd. per hr., no deductions made for time of turning machine and finishing cut at upstream end. The labor cost is 77c. per hour and fuel 30c. per hour.

Two men can operate the machine; three were used here because of the extra amount of labor necessary on the crossings. Two short cutoffs were handled by blasting a ditch through them and then damming the stream by using the machine to build an earth dam and turning the water through the blasted ditch.

The engineer in charge is I. W. Hoffmann, of Carroll, Iowa. The contractor is D. C. Stephens, of Buffalo, N. Y., the work being handled by his western office (815 Hippee Bldg., Des Moines, Iowa), of which H. B. Whitney is Manager. For information we are indebted to Mr. Whitney.

Cross-Section Measurements by a System of Polar Co-ordinates

BY EDWARD L. VERPLANCK*

When steam-shovel excavation began on the Cape Cod Canal, direct tape measurements for obtaining the cross-sections of the cuts became greatly impeded. To facilitate the work, the writer developed a method of surveying in which the center line offset distances were obtained by trigonometric computation from observed angles, instead of by direct measurements.

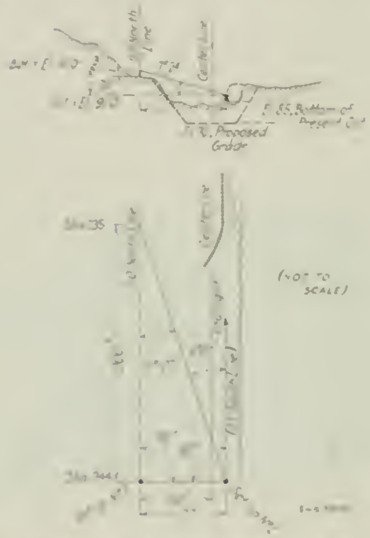


FIG. 1. CROSS-SECTION MEASUREMENTS, CAPE COD CANAL

FIELD OPERATIONS—Referring to Fig. 1, the transit was set up on the permanent reference line 150 ft. north of the center line and a point was established [illegible] near the center line on the cross-section line. The transit was moved to this point and the offset distance from the center line determined by triangulation and the transit [illegible]

CURVED CENTER LINE—This method, with certain modifications, was applied with equal success to the 0° 30' curves of the Cape Cod canal. Fig. 2 shows the layout of such a survey.

The transit was set up on the 150-ft. north reference line and a point established near the center line on the radial section line through the transit station, and the transit was set up over this point and oriented parallel to a tangent of the curve at the station of the cross-section to be taken. A study of Fig. 2 will show the angles necessary to be turned in order to get this orientation.

FIG. 2. CROSS-SECTION MEASUREMENTS ON CURVED CENTER LINE

[illegible]

[illegible]

procedure, besides its extreme rapidity, was the fact that only two men were required to make the survey, a transitman (keeping his own notes) and a rodman. By the direct-tape-measurement method, three men are indispensable.

The work was done under the direction of C. T. Waring, Resident Engineer of the Cape Cod Construction Co., of Sandwich, Mass., of which Wm. Barclay Parsons, of New York City, is Chief Engineer.

Increasing the Height of a Chimney While in Service

An interesting piece of work carried out recently was that of increasing the height of a chimney by 30 ft., and doing this while the chimney was in use. This was at the plant of the Northwestern Malt & Grain Co., Kenton and Cortland Sts., Chicago.

The original stack was 129 ft. high, of square section, 6x6 ft. square inside at the top, and built of common sewer brick. It was desired to increase the height by 30 ft., and this extension is of circular section, 6 ft. diameter, built of radial brick. The top of the old stack (including its cap or cornice) was torn down for 6 ft., and replaced by a connection changing from square to octagonal, this part being built of sewer brick. Above this is the 30-ft. circular extension.

The work was done from an outside scaffold supported on triangular frames. The upper end of each vertical leg was fitted with a hook, engaging a steel cable drawn around the chimney and tightened by a turnbuckle. When the men had laid the brick as high as they could reach, another cable was placed around this new section, with a second set of frames, the lower scaffold and cable being later removed and shifted above the other. An L-shaped builders' derrick on the chimney carried the cable for hoisting men and material. To protect the men from the direct attack of smoke and gases a steel shield, nearly semi-circular in plan, was fitted inside the flue, extending several feet above the brickwork, but on very windy days the men did not work.

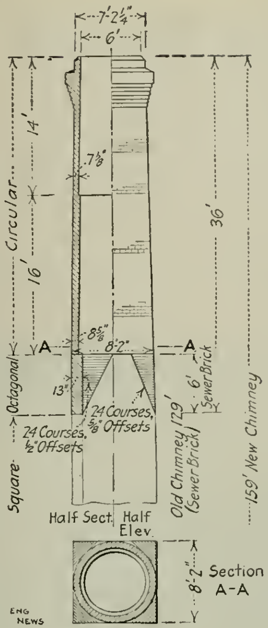

Fig. 2. A 30-Ft. Circular Extension on a 129-Ft. Square Brick Chimney

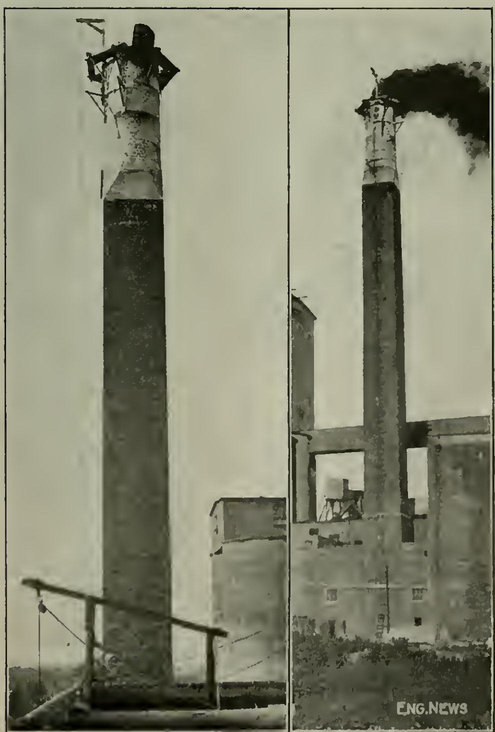

Fig. 1. Building a 30-Ft. Extension to a Brick Chimney

Fig. 1 shows the work very clearly. In the left-hand view may be seen the working platform on its brackets, and two of the brackets at a low level still hooked to the cable around the chimney. At the top are seen the steel shield (at the right) and the hoisting derrick. The derrick near the bottom of the view is for repair work on an adjacent building. The right-hand view shows the entire chimney and shows it during heavy emission of smoke.

This work is being done by the Alphons Custodis Chimney Construction Co., of Chicago. This company has done similar work on a number of chimneys, the extension in one case having been 60 ft. high.

Impact Formula for City Street Bridges—In designing the Bloomfield cantilever bridge, Pittsburgh, Penn., which is just being completed, an impact formula was used, the live-load stresses being increased by a variable percentage to allow for vibration and other traffic effects. The formula used is:

$$I = S \frac{100}{L + 300}$$

where I = impact addition, S = live-load stress, and L = loaded length of bridge in feet. The formula gives an impact addition one-third as great as that applied to railway bridges under a commonly used formula. T. J. Wilkerson is Engineer of Bridges of the City of Pittsburgh.

A Metallic Tape Detachable from the Reel Box by a new device called a "threader" has been patented and placed on the market by the Lufkin Rule Co., of Saginaw, Mich., and will hereafter be furnished with this company's "metallic" woven tapes without extra charge. The "threader" is a loop and stud arrangement, by means of which the tape is securely fastened to the winding drum of the reel, when the tape is in use, but which permits an old worn out tape to be readily detached and replaced by a new one. The life of the tape is generally much shorter than that of the leather case or reel box, so that the latter, which represents about half the first cost of the instrument, may be used as long as it is fit for service.

Patching Concrete Retaining-Walls by a Concrete-Spraying Machine

Extensive patching of surface defects on concrete retaining walls is being done by the Delaware, Lackawanna & Western Ry., at Newark, N. J., where its Morris & Essex division runs through a retained cut a mile long and up to 25 ft. deep. An interesting new concrete-spraying machine is used for the work.

The retaining walls were built about ten years ago. After a few years they began to show serious deterioration on the face—mainly horizontal cracking and spalling at the day's-work planes, but also superficial scaling or sloughing on more extended areas. These defects spread gradually. Finally, during the present year the work of patching the wall was started.

Before patching, the bad spots were cleaned out. The repair gang went through the cut and chiseled out the poor concrete at the points of deterioration, down to solid concrete, usually an inch or so, leaving the wall pretty thoroughly marked up with "holes" ranging in size up to two or three feet wide and up to six feet long, ready for plaster patching.

The first part of the patching, just west of Newark station, was done by hand troweling, using 1:3 cement mortar. Then a concrete-spraying machine, called "Concrete Atomizer," was put on the job, and the rest of the work has been done with it.

The Machine—The "Atomizer," of [illegible] construction [illegible] can be used as [illegible], consists of a closed cylindrical tank with central shaft carrying baffles or paddles and valve [illegible], and a discharge hose [illegible] end of the tank. Mortar materials are fed into the front of the tank, the end opposite the hose outlet. The machine can be operated by steam or by compressed air. Its mechanical construction allows of using large-sized aggregate in the concrete.*

Plant Used—In the Newark work steam at 65 lb. is used to run the "Atomizer," being more conveniently available than air. A switching locomotive furnishes the steam and at the same time hauls the work train, comprising the car carrying the machine and sand, and a caboose or tool car.

Operation—A batch for the machine consists of two pails cement and six pails sand. These materials and the required amount of water are charged in through the front door of the tank, and after closing the door are mixed by turning on steam, which revolves the paddles. Then the outlet valve is opened and the steam pressure forces the mortar out through the hose.

The discharge hose is 2-in. rubber hose, with a nozzle consisting of a short piece of $1\frac{1}{2}$-in. rubber hose choked down by an elliptical band. It can be handled by one man, but in the present work two men are used, as one is needed to carry the pipe to follow the nozzle.

The stream issuing from the nozzle is simply played across the area to be plastered (or concreted), the mortar deposited on the wall is very dense and hardens rapidly (perhaps due to the accelerating effect of the steam). The stream of mortar is surrounded by a cloud of steam so that the nozzle-man cannot always see the surface on which he is working. Little cement or sand drops out of the stream or off the work, however.

Trimming and screeding or smoothing is done by hand after the machine has placed the mortar.

The working force on the Lackawanna wall patching comprises: 2 men feeding, 1 man operating machine, 2 men at nozzle, 1 laborer, 3 or 4 cleaners smoothing up the patches, 1 foreman. The locomotive crew takes care of the steam control.

The "Concrete Atomizer" is controlled by Harold P. Brown, 120 Liberty St., New York, and was leased by him for the Lackawanna work, the railway company furnishing the labor.

Concrete-Spraying Machine Patching the Walls of the Lackawanna Cut, Newark, N. J.

(This machine is operated by a steam jet. A piece of $1\frac{1}{2}$-in. rubber hose serves as sprayer nozzle. The cloud of steam issuing from the nozzle sometimes obscures the work. The applied concrete seems to set very rapidly, perhaps due to the action of the steam.)

Handling Excavation for the William Penn Hotel, Pittsburgh

The large cellar excavation for the new 20-story William Penn Hotel, in Pittsburgh, Penn., called for exceptional methods for handling the dirt, if speed and low cost were to be secured. The contractor met this requirement by installing a highly organized mechanical equipment.

The site is at Sixth and Oliver Aves. and Cherry Way, and measures 216x130 ft.; the depth to be excavated ranges from 40 to 60 ft., with a volume of 50,000 to 60,000 cu.yd. place measurement, including shale and some harder rock. The digging is done by a 1-yd. Thew steam shovel, loading 1½-yd. Koppel steel dump-cars hauled by mules along a narrow-gage track on the floor of the excavation (Fig. 1). At the lower edge of the lot is built a timber hoisting-tower with inclined hoistway in which a 5-yd. dumping skip travels. The skip is patterned after mine or furnace hoist models, though built of timber. The bottom of the hoist is in a pit below the bottom of the excavation, and the narrow-gage cars thus are able to dump directly into the skip. At the top of the hoistway, above the street, the skip tips its load into motor-car trucks (Fig. 2). Three trucks and three trailers are in use, each of about 5 cu.yd. capacity. The haul to the dumping-board is about 1 mi., and some 400 trips are made in 24 hr., nearly three-quarters of the total being handled in the night hours, on account of the clearer streets.

The dumping-board is located on the Allegheny River above the Ninth St. bridge. It is a sort of pontoon bridge, consisting of a planked roadway carried on a pair

Equipment for Handling Excavation for William Penn Hotel, Pittsburgh; James L. Stuart, Contractor

(Dump cars loaded by steam shovel; dumping-skip hoist to lift spoil to street and load the wagons.)

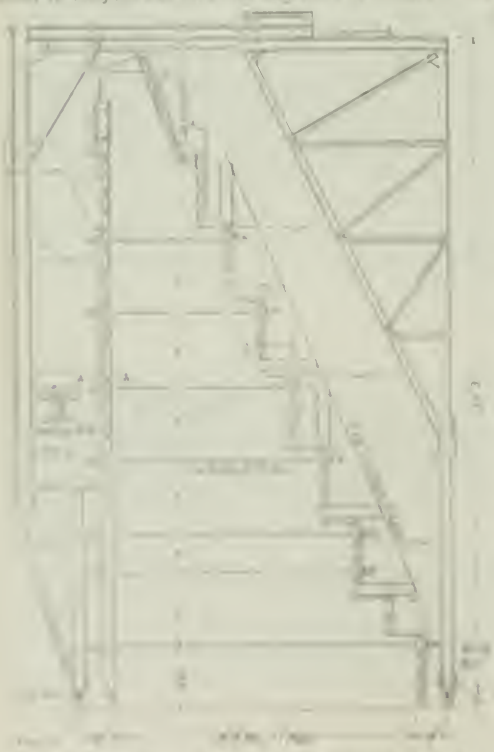
of girders whose outer ends each is supported by two scows. Under the bridge is a bin, into which the trucks dump through a trap in the roadway planking. At the end of the bridge a turntable is built up on the scows. The truck after dumping is turned here and returns to shore running forward. The spoil is taken away on barges carrying 2-yd. boxes, filled from the bin; at the dump the boxes are lifted off by a derrick.

Steel Traveling Forms for Retaining Walls

In the construction of the reinforced-concrete retaining walls for track-elevation work at Chicago, the Rock Island Lines are using traveling forms, some of timber and some of steel. The walls are built in 35-ft. sections.

The accompanying cut is a sectional elevation of the steel form. It consists of a gallows frame traveling on double-flanged wheels on a pair of rails, the width of form (and gage of track) varying from 13 to 21 ft., according to the size of the wall. The width is varied by sliding the rear part of the frame inward or outward, each top cross-beam of the frame being made in two overlapping sections, as shown. The faceplate rests on a longitudinal sill and steel channel and is attached to the cross-beam of the gallows frame, while it is tied back to the rear of the form by a series of tie rods.

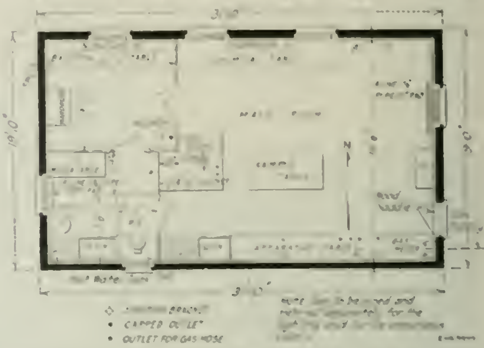
The steel forms were built by the Blaw Steel Construction Co., of Pittsburgh, Penn., and were designed by them in conjunction with the engineers in charge of the work, which is being done by the railway company under the direction of R. H. Ford, Engineer of Track Elevation.



Steel Traveling Forms for Retaining Walls

A Compact Laboratory for Sewage-Purification Experiments

An experiment laboratory built by the Bureau of Sewers of the Borough of Brooklyn, New York City, is shown in the accompanying plan. The laboratory is designed to handle a large number of samples daily from the various units of the sewage-experiment plant, located at the 26th Ward pumping station, near Jamaica Bay. E. J. Fort is Chief Engineer and George T. Hammond is Engineer of Design of the Brooklyn Sewer Bureau, and William T. Carpenter is chemist in charge of the laboratory.



Sewage-Purification Experiment Laboratory, Brooklyn, N. Y.

Moving an Old Stone Church with Screw Jacks

The Mott Haven Church, New York City, an old brownstone structure built in 1855, was recently moved to a new position on the same lot. The building formerly fronted on Third Ave.; it was moved back 50 ft. and swung around to face 146th St.

The first procedure was to tie across inside the building with steel cables fastened to beams spanning the outside of the windows. Holes were broken in the foundation to permit the placing of longitudinal or rolling sticks. Cross-timbers were placed under these, running in some instances the entire width of the building and in others only through the wall, being supported by cribwork on the inside. Screwing sticks were then placed longitudinally under the cross-timbers and [illegible] jacks placed under the screwing sticks. The weight was then taken off the old foundation and the latter demolished.

About 15 [illegible] were placed under the building, extending in the direction of proposed movement. The jacks were then removed and dropped on their sides on the rails, so that their heads pointed in the direction of movement and pressed against the screwing sticks (the other timbering had been removed). The screw jacks, acting horizontally, moved the building as desired.

The church was moved by the [illegible] House Moving Co., [illegible] E. 146th St., New York City, in about a month. The work required 15 men and a foreman.

A Useful but Inexpensive Boat for Surveyors

By F. W. Salmon*

The boat shown in the accompanying figure can easily be made in two working days by any two men having a little handiness with tools. If pine pitch is used for the outside, instead of paint, and "enamel" or paint mixed with a good proportion of quick-drying varnish for the inside, it can be put in the water and used the evening of the second day—provided that the material is roughed out to size in a sash-and-door factory or similar mill.

To get the proper shape of the sideboards, I carefully made a small model of the outer surface to scale and drew a piece of strong paper over this tightly and marked the edges; on removing the paper of course there was a plain template of the outside of the skin, from which the figures are given to enable anyone readily to reproduce it. I have made several boats from "sawn stuff" by such templates and find that they come out amply close to the intended dimensions for general use and it saves a lot of time, labor and money.

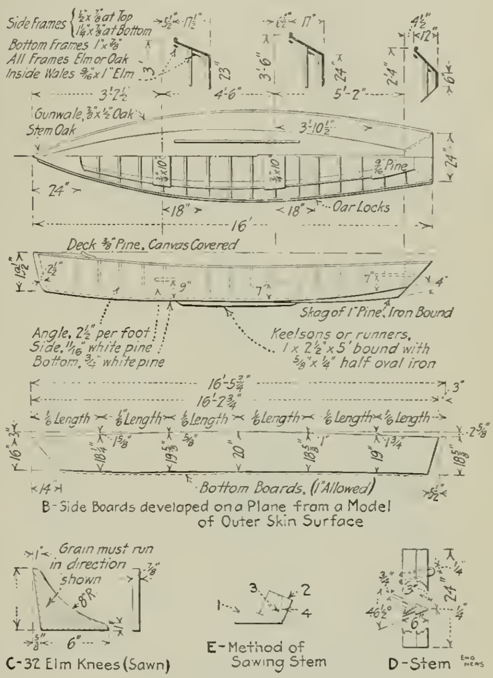
The boat handles well in choppy water. As the stern is undercut, the bow rises quickly to waves, keeping the boat dry. There being no deck, there is ample room for poles and tents. On ordinary waters, four men can be carried safely and well, or two men and a camp outfit.

If made of pine or basswood, the boat weighs about 250 lb. with four 8-ft. ash oars and rowlocks. The material costs some $12, where one man goes to the mill and lays out the pieces for cutting. As these millmen do not often get out material for boats, I have shown in *E* the scheme of sawing the stem. Generally, for a boat of this style and size it is made out of a piece of 6x6-in. timber. Tack on two wedges, 1, cut at 23¼° angle; then on a circular ripsaw cut off the piece 2, and after lowering the saw (or raising the saw-table) make the cut 3; after this the timber can be reversed end for end on the wedges and the other side cut so as to give the general outline desired and the second cut 3. Remove the wedges and make the cuts 4 from each side. To set up the boat, first the frames at the seats are rigidly put together with eight-penny iron-wire nails on form boards secured to a stiff plank, or a 4x4 in. Then the two sides, sawn as shown, are drawn down on these with ropes and the stem carefully fitted and nailed. Care must be taken that the distance from the stem to the seat on the right is exactly the same as on the left, measured along the top edge of the side, to insure having the seats at right angles to the center line of the boat when finished. Fit the stern carefully and secure all parts well. Dress off the bottom edges of the side planking, after turning the boat bottom up, so that the bottom boards will be tight. Put these on lengthwise after trimming the stem.

The boat can next be turned right side up, the bottom and side frames fitted and secured, the elm knees marked and cut at the angle to fit each place and all nailed, the inside wales and outside gunwale fitted and well nailed, and the stern seat and front deck put in.

When assembling the parts, surfaces that come in contact should be given a coat of paint, such as thick white lead ground in oil and thinned with spar varnish and turpentine. This is not very often done in the cheaper boats, but adds to their tightness and durability. The seams may be calked lightly with cotton where necessary. The boat should be painted inside, turned over and pitched with hot pine pitch if wanted for immediate use and at the least expense. The outside may be painted if more time can be allowed and more expense incurred.

An iron U-bolt should be put through the stem post, as shown in *D*, for the painter—which is usually a ⅝-in.



Plans of a Surveyor's Boat

hemp rope. The rowlocks should be secured to the boat by a cord or small chain. Some people like a floor inside on the frames; two boards 10 in. wide, of ⅜- to ½-in. stuff, can be laid loose or secured.

Few tools are required if the material is roughed out at the mill—a hammer, hatchet, smoothing plane, firmer chisel, brace and bits, including a screwdriver, and a crosscut saw, cover everything.

*607 N. 20th St., Birmingham, Ala.

NOTES

A Real Novelty in Stadia Methods—J. Zwicky, of St Gallen, Switzerland, has brought out a radical novelty in the field of stadia measurement. Instead of using two horizontal crosswires in the telescope reticule as stadia interval, he forms a horizontal stadia interval by using two telescopes whose horizontal axes make a small angle with each other In the instrument as practically constructed, one of the telescopes is mounted immediately above the other, and a link connection causes the two telescopes to rotate together vertically. Since both telescopes revolve in vertical planes, the intercept which they cut off on a horizontally held stadia rod is proportional to the horizontal distance between instrument and rod, instead of being proportional to the slope distance (as with upright rod held normal to the line of sight, or with horizontal rod and ordinary stadia wires), or proper

tional to a function of the slope distance, as with ordinary vertical stadia rod.

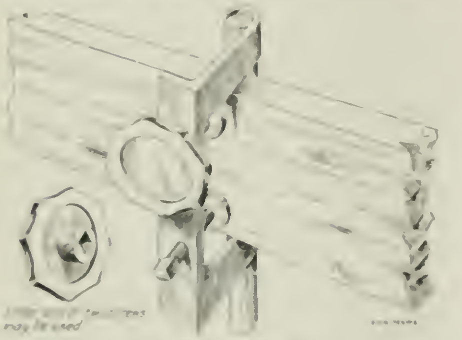
The two [illegible] advantages of this instrument and stadia method are claimed to be: (1) the possibility of using a much smaller stadia ratio than 1:100, thus permitting the attainment of much greater accuracy on ordinary lengths of sight; (2) the elimination of [illegible] calculations to get horizontal distances. The former advantage permits of getting a precision of better than 1 : 1000. In a survey of an [illegible]-acre tract, where all measurements (except those in woodland, where the tape was used) were made by the stadia method (with interval 1 : 2[illegible]), a precision of about 1 in 3000 was obtained.

Holding the rod in horizontal position needs two rodmen instead of one, which is a counterbalancing disadvantage.

To eliminate calculation for obtaining elevations also, a reduction chart is attached to the side of the transit standards and a pointer fixed to the horizontal axis of rotation moves over this chart as the telescope is revolved.

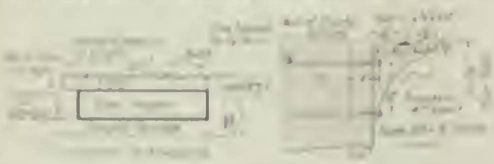
The inventor describes the new method and instrument in the "Schweizerische Bauzeitung" of Sept. 5, 1914.

A Reusable Batter Board—The accompanying drawing shows the details of a batter board device, patent for which has been applied for by R. H. Peck, an engineer of New York City. The device may be used in any kind of work requiring the batter boards, but by the diagram it is illustrated in use on a sewer trench. It consists of two iron rods which are driven into the ground and for each rod a [illegible] which clamps the iron rod and at the same time allows between the rod and the spring yoke, for a plank anywhere from [illegible] to [illegible] in. thick. This plank, which is used for the batter board, is then clamped tight against the [illegible] by a screw with a large flat plate head.



A PATENT BATTER BOARD

A 100-Ft. Length-Standard Bar has been installed in a [illegible] of the city hall at [illegible] for standardizing tapes and other measures. [illegible]



[illegible]

1 meter, 1 ft., 25 ft., 50 ft., 66 ft., 25 meters, 30 meters and 100 ft. At the zero end of the rod there is provided a clamp for holding the end of a tape line to be tested. At the other end there is provided a spring balance. The rod was graduated in October, 1913, by Prof. L. A. Fischer, of the U. S. Bureau of Standards. It was officially accepted by ordinance of the City Council on Mar. 30, 1914. It is put under the charge of the superintendent of [illegible], and a set of rules has been drawn up governing its use. A bronze tablet on the wall sets forth that this standard was presented to the city by the Western Society of Engineers and installed by Peter [illegible]. The society's committee which has had the matter in charge is composed of G. A. M. Liljencrantz (chairman), C. D. Hill and A. C. Schrader.

A New Steel Sheetpile of Very Light Weight has just been brought out by the Lackawanna Steel Co. It is of the section shown in the cut herewith, and is intended to be used for core walls and cutoff walls of dams or levees, protective cutoffs in difficult excavation work, etc.

The pile is 8 in. wide [illegible] of interlocks, and is curved transversely to a versed sine of 1¼ in. Alternate piles are turned in opposite directions, and thus produce a wall thickness of 2½ in. out to out. The metal thickness is [illegible] in.; the pile weighs 7.66 lb. per lin.ft. or 11.[illegible] lb. per sq.ft. of wall.

NEW LACKAWANNA SHEETPILE

The resisting moment of the pile section (taken singly) at 16,000 lb. stress in the extreme fiber, is 11,810 in.-lb.

This pile has been used recently in some levee work on the Mississippi River, and a large amount is to be used shortly in subway construction in New York City, for protecting existing foundations against soil movement.

Filling a Park Area with Spoil; Transportation Difficulties—In Cleveland, Ohio, some 85,000 cu.yd. of excavation from the site of the W. Bingham Co.'s new building on West Ninth St., near St. Clair Ave., is being used for filling low-lying park area some 1½ mi. away. Herstein Park, a newly created playground on waste low land alongside a congested district, near East 27th St. and the Nickel Plate tracks, is being filled. The city pays 1[illegible] per yd. for unloading and spreading, and the contract price for the excavation is $7[illegible], so that the contractor receives in all $1.62 per cu.yd. Apparently he is handling it at a fair profit in spite of quite unfavorable conditions. The material is a moist sand and clay mixture. It is handled from the excavation directly into Western air-dump cars on the Big Four tracks near the excavation site, and is transported by the contractor's own locomotives (with railway company crews) to the park via Big Four and Nickel Plate. There is considerable delay at the transfer point, and also at the Nickel Plate viaduct over the Cuyahoga River, which is being reconstructed, and is operated single-track under slow orders. The biggest day's handling has been 2[illegible] cars averaging [illegible] cu.yd. The Fred R. Jones Co., Inc., of Chicago, is the contractor.

Rules for Setting and Starting Water Meters—Before cutting the service pipe, flush it thoroughly to remove the sediment, sand and gravel which are liable to make trouble if washed into the meter. After cutting and threading the pipe remove thread-cutting chips from inside the end of the pipe.

Editorials

Heavy Construction Work on the Grand Trunk Pacific Ry.

While the Grand Trunk Pacific Ry. has secured a specially favorable location for the Rocky Mountain section of its transcontinental line as far as grades and a low summit elevation go, the construction of this part of the line has been attended with exceptional difficulties. These difficulties arise from three causes: the severe winter climate, the topography and almost inaccessible character of the country, and the character of the streams which had to be utilized for transportation of material.

The necessity for expediting the progress of the work made it necessary to commence construction at various points, and this, in turn, made necessary the transportation of men, machinery and supplies to points not only difficult of access but often cut off entirely from any means of communication. These conditions of carrying on the work are illustrated in an article published elsewhere in this issue describing some of the bridge substructure work, and written by one of the men in direct charge of this construction.

In ordinary railway construction it is usual practice to build temporary bridges in advance and thus to have a line of communication open with the base of supplies. But in the case of the Grand Trunk Pacific Ry. there were many cases where temporary bridges could not be built or would be constantly liable to destruction, and it was desired to have the substructures for permanent bridges built in advance, so as to be ready for the steel superstructures when the tracklaying reached them. This necessitated establishing construction camps in distant mountain regions, where the means of communication were very limited and were liable to be interrupted entirely for considerable periods. Under such conditions ample supply of provisions, equipment and machinery parts was essential. Still more essential was the placing of the work in the hands of resourceful men who could turn emergencies into opportunities and could keep the work in progress whatever might happen.

Where the line follows the general course of the Fraser River, the river was adopted as a means of distributing material to the construction points, including the three long bridges which cross it. The river is navigable only at high-water period, which is during the summer, and is then too high and turbulent for construction work in the stream. The low-water period available for bridge construction occurs during the winter, which is very severe, the temperature continuing at 40 to 50° below zero for considerable lengths of time. Under these conditions, much of the heavy material and supplies had to be taken to the sites in summer, by means of scows floating down a dangerous channel with a wild current and numerous rapids. In winter, with everything frozen solid, the coffer-dams were built, excavations made, and concrete deposited for the foundations and piers. But the work was planned to meet these conditions and was carried out successfully, while the concrete proved to be of excellent character, indicating once more that proper precaution and expense can make winter concreting quite practicable.

In winter there was communication by sled on the river, except when the snow was too deep, and this was the most favorable time to deliver material, owing to the dangers of navigation in summer. During some winters, there is comparatively little snow, and in the hope of experiencing this condition the bridge contractors purchased and delivered a large motor truck with trailer wagons. Their hopes were not fulfilled, however, and the heavy snow made this costly equipment quite ineffective. In one case, materials and plant were hauled by sleds about 150 miles over the frozen river, between points about 100 miles distant by the future railway but quite inaccessible by land. For another of the bridges, a considerable part of the material was carried on scows for nearly 300 miles.

Ben Franklin Vindicated

The decline in popularity of lightning rods, following the pernicious activity of rascally agents, left a stain on the scientific reputation of the great and wise Ben Franklin, who developed this protection against thunder bolts. Scientists have stoutly defended the value of such equipment, if well put up, but, nevertheless, practical men, often speaking from bitter experience, have maintained continuously for generations that the rods have proved worse than useless.

Two valiant defenders of the faith, Professors J. B. Reynolds and W. H. Day, of the Ontario Agricultural College, not contented with the inconclusive deadlock of theory and claimed fact, set out to find the truth—in practicable demonstrable form. For ten years, first one and then the other industriously collected all possible information about buildings reported struck by lightning in Ontario. At the end of this time (1910), they had data on 599 buildings struck by lightning. Of this number struck, 317, or 53.6%, were burned, but only 18 of the buildings struck, or 3%, had rods and only three of these, or 16.6%, of the protected buildings were burned. Having these interesting but incomplete figures, the investigators desired to know further the number and experience with unrodded buildings in the province, so that they might complete their case—reasoning that if rods neither prevented nor induced strokes the ratio of damaged to undamaged structures in the unprotected risks would be of the same order of magnitude as in the rodded.

Great difficulty was found in securing the desired data. Eventually, however, the Provincial mutual insurance companies were interested in the studies and reports covering about a fourth of the province were secured after some delay. These showed that 21% of insured farm buildings were rodded and that of all those struck only 1½% were rodded. Out of 7000 unprotected buildings, 37 were struck; out of 7000 protected ones only two

were struck. [illegible] 57 were saved out of 67 expected to be struck, or a probable protection of 91.5%, and that with uninspected rod construction.

Prof. Day visited Iowa and Michigan to inspect the insurance records and evidences of protection there. In Iowa, he found that the total claims paid for lightning losses in eight years amounted to $1081 on rodded buildings and $70,000 on unprotected ones. Apparently then, for each dollar paid on rodded risks $70 was paid on unrodded. The rods were not inspected and some of the losses probably were due to poor construction. Even so, the protection shown was 98.7%. In Michigan, one mutual company insuring only rodded and inspected buildings, in four years paid $72 claims on $55,172,075 risk. Another mutual company taking both protected and unprotected risks paid $82,294 in claims on a total of $58,[illegible] in the same period. The loss was practically all on unprotected buildings aggregating $17,553,818 in value of risks. Comparing the two companies, for each $1 damage on protected buildings there seemed to be paid $[illegible] on unprotected ones—an obvious protection of 99.9%. All this and more is set forth at length in a recent bulletin of the Ontario Department of Agriculture.

Regarding the technique of the rod construction so successfully employed in these states, it is of interest to know that, where knowledge was available, there appeared to have been used more or less of an approach to a cage of conductors about the building. The rods were fastened both close to and away from buildings but without insulators. Poorly buried ground plates and rods were found and where these groundings proved defective there invariably developed disaster.

The worthlessness of the old lightning rods, of course, was the fault of the ignorant fly-by-night agent who carelessly put up his cheap affairs, gathered his money and disappeared, leaving disaster and ruin for many a farmer in the approach of the first heavy electrical storm. A deliberate attempt to discredit the great American philosopher and patriot could not have worked as well. It is a source of much satisfaction to see definite figures which substantiate the soundness of his scientific knowledge as well as that of a long line of later physicists.

The Submarine Vessel as a Factor in Naval Warfare

The destruction wrought upon United States wooden war vessels by the Confederate ironclad "Merrimac" in Hampton Roads during the Civil War, closely followed by the conflict between the "Merrimac" and the "Monitor," changed the entire trend of naval construction. It is quite within the possibilities that the recent sinking of three British cruisers in the North Sea by a German submarine boat will constitute equally profound change in the world's navies. The control of the seas has hitherto belonged to the power able to build and to man the largest number of fighting ships, with armor and armament sufficient to enable them to vanquish their antagonists. But of what use to build these huge floating fortresses at enormous expense if they had their very act at any time likely to meet destruction by an insignificant antagonist hidden in the ocean depth?

It was the course of the development of the submarine boats to accomplish this very thing. During the fifteen years or so since the first submarine boats were built there has been no war between nations owning sufficient submarines to test the possibilities of their action. Yet an eminent British admiral, only a few weeks before the outbreak of the war, expressed his belief that the development of the submarine boat had reached a stage that rendered battleships obsolete. This prediction is recalled in connection with the news of the recent serious disaster to the British fleet.

Of great significance is the detailed account of the circumstances under which the British cruisers were sunk. As has been fully reported in the newspapers, it appears that the doomed cruisers were in the open ocean far from the coast with no thought of an enemy being near. It may never be positively known whether anyone on the first cruiser sunk saw even the periscope of the attacking submarine before its torpedo exploded. At any rate, the attacking vessel, if seen at all, was seen too late to make any effective defense. The two other cruisers, a mile or two distant, saw the plight of their sister vessel and supposing it to have struck a floating mine came near to rescue the crews struggling in the water, when the submarine torpedoed these cruisers also. The number of men lost in this brief and inglorious battle, if battle it can be called, equalled the losses in some of the most famous naval battles in history.

Another significant outcome of the loss of these three cruisers is the issue of orders by the British Admiralty that in case one vessel of a fleet is torpedoed by a submarine boat, other vessels in the fleet must look to their own safety and not run the harmful attendant of rescuing the crew of the stricken vessel. It is difficult to read any other interpretation from this order than that the proper tactics for a naval vessel, as soon as it learns that a submarine boat of the enemy is near, is ignominious flight. It may be the most powerful cruiser or the latest super-dreadnought battleship, yet its fighting power is of so little avail for defense against this hidden foe that its only refuge is to seek safety through superior speed.

It is fair to say, on the other hand, that the submarine boat, while it has reached a high degree of mechanical perfection, is still subject to serious limitations. Were it not for these limitations, the losses of naval vessels torpedoed by submarines since the beginning of hostilities would already have been far more numerous. The submarine can carry only a limited amount of supplies; it must operate either within a definite radius of a shore station or else it is dependent on a supply ship. Its speed is limited, and what is most important of all is its inability to locate its adversary when running submerged.

The modern submarine boat is more properly termed a submersible boat. In normal operation a considerable part of its hull is above the surface. On sighting and identifying an enemy's vessel the boat sinks in the water leaving only its periscope above the water. From this point of observation, the course of the submarine is directed until it is near enough to the enemy so that there is danger of discovery. From that point onward the journey must be entirely under water, coming to the surface only when absolutely necessary to verify the course and distance. If at such a time some lookout on the threatened vessel discovers the submarine, instant efforts will be made to discharge a machine-gun volley at the periscope. If successful, the blinded submarine will probably come to the surface where its thin hull will be quickly pierced by shots.

The tactics of the submarine, therefore, are to seek an enemy's vessel when darkness or storm or fog makes observation difficult, so that its approach may be undiscovered.

The difficulty of navigating a submarine vessel under the conditions of attack and of effectively discharging its torpedoes are well known and have caused many naval authorities to regard the submarine boat with skepticism and to continue to pin their faith to big battleships and cruisers.

Nevertheless, the mere possibilities of submarine attack have already revolutionized the naval blockade. The close blockading, which was the ordinary practice in warfare a generation ago, is now too hazardous. It is even an open question, which the present war may settle, whether such a blockade with the vessels perhaps 200 miles off the coast at times can be considered an effective blockade in international law.

It would be indeed a marvelous event in the progress of invention and discovery if the development of submarine navigation should render obsolete the enormously expensive cruisers and battleships on which the great powers of the world have chiefly relied for naval supremacy. It is quite possible that the submarine boat may so greatly increase the defensive power of the smaller nations that they may make themselves invulnerable from an attack by sea on the part of even the most powerful nations by the possession of even a small fleet of comparatively inexpensive submarine boats.

Standard Specifications for Steam-Boiler Construction and Operation

Of all the work done by engineering societies, probably the most valuable and important is the establishment of standard practice on matters with which the members of the Society have to deal. A task of this sort which is just now attracting much attention is the work which a committee of the American Society of Mechanical Engineers is doing in framing a standard specification for boiler construction and operation suitable for enactment by State legislatures.

The first appeal to the Society to take up this task came from the boiler manufacturers. The State of Massachusetts a number of years ago passed a law governing the construction and inspection of steam boilers, which has without a doubt been a great factor in reducing the risk to life and property from steam-boiler explosions in that state. In recent years, a half-dozen other states have followed Massachusetts' example and while they have generally taken the Massachusetts law as a foundation, they have made various minor changes which have become the source of a vast deal of trouble to the boiler manufacturer.

Slight differences in the quality and character of the material, acceptable in one state and not acceptable in another, make it necessary for the boiler manufacturer to keep materials for use in boilers for different states separate as they pass through the shop. The difficulties and expense involved in this in a large establishment can readily be understood. Besides this, there is the risk that through some unintentional error, material intended for use in one state may be accidentally used in a boiler intended for use in another state.

This legislation is already a most serious matter to the boiler manufacturers, when only half a dozen states or so have laws in force regarding steam-boiler construction. One can well imagine the situation, therefore, if instead of a half-dozen states, thirty or forty states had each laws governing boiler construction differing in various details and requirements. Such a condition, however, has actually been threatened. The very fact that some states have laws specifying what boiler materials will be accepted operates to give them the better class of steel and of boilers, and the boiler makers sell the material which would be refused in states which have no such legislation.

It is a realization of this condition, as well as a general movement toward more stringent protection of public safety, that has caused the authorities of a dozen or more states to draft laws upon the subject which are likely to be presented to the legislatures when in session next winter. It is, in fact, authoritatively stated that a number of states would have passed laws a year ago save for the urgent appeals of engineers that action should be delayed until a model law had been framed by the American Society of Mechanical Engineers which could be generally adopted.

The Mechanical Engineers' committee which has been at work upon the proposed standard code completed a preliminary draft last spring which was printed and sent to 2000 engineers representative of all the different interests connected with boiler construction, operation, inspection, etc., with requests for detailed study and criticism. While some preliminary discussion of this tentative draft took place at the St. Paul meeting of the Society in June, the main discussion took place at a special meeting of the committee held in the Engineering Societies' Building, New York City, on Sept. 15, at which nearly 150 engineers were present. The discussion was most active and in some instances heated. Eventually, however, a spirit of harmony and willingness to compromise prevailed.

The discussion made clear that a specification for steam boilers to be embodied in a statute should be general rather than specific. It should embody only the most essential features necessary to safety in boiler construction. It was clearly brought out that to embody in such a code certain specific requirements which might be advantageous for certain classes of boilers would operate as a serious handicap in the construction and operation of other classes of boilers widely different in their design.

The committee is now engaged in the large task of analyzing and studying the large amount of written and oral discussion and criticism it has received and will, it is expected, present its final report for adoption by the Society at the December meeting. Doubtless there will be further active discussion there on some controverted points in the specifications. It seems likely, however, that the report will be finally adopted at that meeting and made available for such state legislatures as choose to act upon it, since further delay, as has been already pointed out, would mean a still worse chaos in state legislation on boiler construction.

It is of interest to note that this voluntary action by a technical society seems to have been practically the only way to save a very important branch of industry from an impossible situation. The desirability of protecting the

public safety or making boiler construction and operation a matter governed by law will be almost universally conceded, but while the Federal Government under the Constitution may and does control the construction of steam boilers used on vessels navigating waters over which the United States Government has jurisdiction and also controls the boilers of railway locomotives employed in interstate traffic, the construction of other classes of boilers has been held to be a matter purely within the police power of the several states and not subject to Federal regulation.

If, however, each state were to independently draft a law regulating steam-boiler construction and inspection, it would be almost as great a barrier upon interstate commerce in this industry as would exist if the several states erected tariff walls around their borders and collected customs on all imports. It is, therefore, the highest kind of public service to have a national engineering society step forward in this difficult situation and take the lead in framing a law which will have the professional prestige of the society behind it and can be accepted by the various state legislatures, therefore, as a safer and more intelligent guide to their work than they could hope to secure from any experts within their own boundaries.

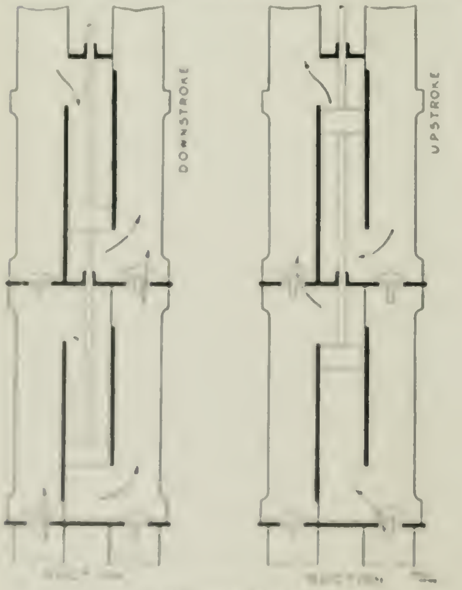
It is worth emphasis, too, that the American Society of Mechanical Engineers is probably the only technical society which could have successfully undertaken this work. Were any commercial organization to take it up, representing any special trade or interest, such as the boiler manufacturers or the steel manufacturers, for example, legislators would naturally be suspicious that the legislation offered was framed to protect some commercial interest, and however unjust or unfair such a suspicion might be, it would have undoubted weight in hindering the adoption of such legislation in many states.

The model law to be framed by the American Society of Mechanical Engineers, however, should be free from any such handicap. There is every indication, moreover, that by the time the law is finally perfected all the interests concerned will be satisfied that they have had a fair hearing and that their representatives have received impartial consideration and they should therefore be counted on for its support. The Society in this task, therefore, is rendering a service not only to the public but to the entire engineering industry.

Letters to the Editor

Another Wonder Pump

Sir—About three years ago the writer was called upon to analyze the working of a pump, which, while evidently similar to the one described in the letter of L. M. H. in the issue of Aug. 27, is far ahead of it in the matter of efficiency—in the mind of the inventor. The accompanying sketch shows the operation of the pump, explained as follows:



A Wonder Pump

DOWN STROKE—The two pistons force water up the right hand pipe, the lower piston draws water into the left hand lower cylinder, the upper valve on left hand side is closed so the weight of water in left hand pipe is forced against the top of the upper piston thereby balancing the same amount of water in the right hand pipe.

UP STROKE—The upper valve on the right closes, forcing the weight of the right hand water column against the bottom of the upper piston and thereby lifting the water in the left hand pipe, while the lower piston draws water into the lower right hand cylinder. We thereby get a complete balance on all water above the pump in each pipe, making it possible to lift the water any distance by the use of just enough power to push the water the length of the stroke plus friction in the pipe. The pump requires two pipes of the same size the full height the water is to be raised.

The 200% efficiency of the pump mentioned by L. M. H. pales into insignificance beside the performance of this prodigy. Conceive of the ease and low cost by which water could be raised 500 ft. by the expenditure of merely enough energy to raise it one foot (plus a little friction) on a 12-in. stroke!

E. J. C.

Moscow, Idaho, Sept. 2, 1914.

A Problem in Mechanics

Sir—The problem stated takes [illegible] readers of Engineering News. While the principles involved are simple, the writer found it difficult to demonstrate them to five or six intelligent people, after a week of intermittent discussion followed by an experiment carried out with all conditions exactly as in the problem. Among those interested was a professor of physics, who was not

convinced, even after the experiment! Here is the problem:

A man on shore is exerting himself to his utmost in pulling a boat toward him by means of a long rope. The off-shore end of the rope is not made fast to the boat, but is held in the hands of a man in the boat. If the man in the boat exerts himself by pulling the rope into the boat, will the boat move faster than if he does not so exert himself, and why?

There is no "catch" in the problem and no question of accelerated motion. Those to whom the problem is a puzzle reason as follows: How can the boat move faster without an increase of tension in the rope; and if the shore man is already pulling his best upon the rope, how can the tension be increased by the mere fact of the man in the boat going to work?

The answer to the problem is that the boat will move faster when both men haul in the rope. The fallacy in the statement above which makes the problem a puzzle to many is that the maximum force a man can exert is a constant quantity. It is not a constant quantity, but is a function of the speed of application. To express it in simpler terms: The force exerted by the man on shore is not so great as he might exert were he pulling on a rope anchored to an immovable object. The man in the boat is therefore capable of exerting a greater force on the rope than he does when merely acting as an anchor. When he attempts to do this, the increased pull checks the speed of the shore man with a concomitant increase in the force which he exerts, forming the increased reaction to the increased pull from the boat. Hence the tension in the rope increases, and therefore the speed of the boat increases, even though the rope goes ashore more slowly, bcause the speed of the boat is now the sum of the speed of the rope going ashore plus the speed of the rope entering the boat.

In an experiment carried out with a rowboat, the shore man acting alone was able to pull the boat over a given course in 21 to 23 seconds. When the boatman applied himself also, the boat covered the same course in 14 to 16 seconds.

The resistance to a boat moving through the water is roughly proportionate to the square of the speed. If we assume that the maximum force exerted by a man is inversely proportional to the speed of application, it is easy to make the problem quantitative, and to show the speed with two men as against one to be an increase of $\sqrt[3]{2}$ times.

While the men are supposed to apply themselves in the same way, it makes no difference what that way is. They may take in the rope hand over hand, they may run bodily back with it or they may turn a windless. The same conditions would hold if we substituted steam winches or electric winches.

Chas. A. Gilchrist.

2401 Le Conte Ave., Berkeley, Calif., Sept. 11, 1914.

Creeping of Asphalt Block Pavements

Sir—In Engineering News of July 16, 1914, p. 130, there are some notes on the creeping of asphalt-block pavements. Though the instances given show more movement of the courses than commonly found, practically all asphalt-block pavements show this creeping.

The first case noted by the writer was in 1907 or 1908 on the Southern Boulevard, south of Freeman St., New York City, a year or 18 months after the completion of the pavement. The east roadway carrying uptown traffic has a down grade of about 4% in the direction of travel, and the courses of blocks showed a movement of 18 or 20 in. then. Blocks, which as laid were 12x5x3 in. thick have been found squeezed by the traffic to 16 in. long, 6 in. wide and 1½ in. thick, and in other cases to 5 in. thick and proportionately narrow.

In the writer's opinion the creeping is due to the traffic crowding the blocks closer together, a small movement at each joint amounting to a considerable distance in a city block. As there are about 240 joints in 100 ft., ⅛ in. on each joint would amount to 30 in. This space is filled by the spreading of individual blocks, most of which show slight spreading, at least on top.

The irregularity on asphalt-block pavements is also due in the writer's opinion to the spreading of the blocks permitted by the open joints. These will usually average about ¼ in. when the pavement is laid, but soon the blocks show absolutely close joints, only a skin of dirt separating adjacent blocks. This spreading of the block allows it to be gradually rolled out to a thickness of 1½ to 2 in., making a decided hollow, which rapidly increases in size, as it holds water and has to sustain blows of wheels as they drop from the higher blocks.

The creeping of the courses in wood-block pavement is also noticeable, but from a different cause. It is usually due to the swelling of the blocks at cuts or openings where the pressure has been relieved and the pavement is free to swell, thus allowing the courses to assume a curved line where originally they were straight.

R. A. MacGregor.

2428 Lorillard Pl., New York City, Sept. 8, 1914.

Record Season of Pavement Construction in Montreal, Que.—To the first of September about 25 miles of new pavements had been laid on Montreal streets since the present season's work began. This is about 250,000 sq.yd.

The Progress of Work on the New York Barge Canal is summarized by State Engineer John A. Bensel in the "Barge Canal Bulletin" for August. On the Champlain Canal from Whiteball, the southern end of navigation on Lake Champlain, south to Northumberland, a distance of 30 miles, the canal is finished. The completion of the entire Champlain Canal awaits the completion of the Troy Dam by the United States Government. A branch from the main line of the barge canal to Oswego on Lake Ontario will be finished next season, ready for the opening of the new waterway in 1916. Federal Government work will be necessary to deepen the harbor at Oswego to 12 ft.

Of the 346 miles of canal between Albany and Buffalo, about 70% has been completed and turned over to the state. At the western end the work is all completed from Tonawanda to a point about 6 miles west of Rochester. Work has been delayed east of Rochester by litigation over six railway crossings. This litigation has now ended, and the work will proceed rapidly, so that next year should see the completion of the work all the way from Rochester to Fox Ridge, near Syracuse, and between Fox Ridge and Utica.

The work on the canal terminals, which is being done under a separate bond issue, is also making rapid progress, and will be ready when the barge canal is completed. The Whiteball terminal is already finished, and the terminal at Albany has already received lumber vessels from Florida. The Troy terminal is under contract, and work has begun at Buffalo and Oswego.

A table in the report shows that on completed contracts for the barge canal work, $37,266,000 has been expended, and on contracts now in force, $31,600,000 has been expended, a total of $68,806,000 worth of work completed to Aug. 1. The total work completed to July 1 includes 87,690,000 yd. of excavation, 1,200,000 yd. of embankment, 2,416,000 cu.yd. of concrete, 1,408,000 cu.yd. of rough stone work of all classes, 22,000,000 ft. B. M. of lumber, and 82,000,000 lb. of metal work.

The Prismatic Astrolabe, A New Instrument for Determining Latitude and Time by Equal Altitudes

By David Binns*

The method of equal altitudes for the astronomic determination of the observer's position upon the earth's surface leads to results of such surprising accuracy that it has been termed incontestably superior to any other. As the name suggests, this method calls for the observation of celestial bodies in various portions of the heavens,

Fig. 1. Elements of the Prismatic Astrolabe

but always at the same altitude, the observation consisting merely in noting the time when this altitude is attained.

As the altitude itself is entirely eliminated from the results in the course of the computation, its exact value, affected by constant errors of graduation, eccentricity, level, collimation, azimuth, flexure, etc., is of no consequence, provided only that it is the same for all stars observed. The local time and the latitude thus obtained, free from systematic error due to these sources, are remarkably precise.

The method itself was introduced by Gauss, who first pointed out its advantages a century ago. Employing a sextant and artificial horizon, this illustrious mathematician, even with such crude apparatus, and with only three stars, obtained a value for latitude which excited wonder. After Gauss, others experimented with the sextant; but only the brightest stars can be observed with this little instrument. Very few of these can be found at a given altitude within a reasonably short period of time, and the small magnification necessarily employed to permit keeping the star in the field of view is not conducive to sharp observation. Sextant work cannot be relied upon for work of extreme precision.

Experiments were accordingly made with theodolites and other instruments rotatable around a stable vertical axis, and very good results were obtained by careful manipulation; but the artificial horizon was here replaced by some device like the spirit level, and this reintroduced the elements of systematic error. The method of equal altitudes, therefore, despite its advantages, though employed extensively at sea, was long neglected on land.

Recently, the French took hold of the problem, and, as their persistent way called for, by inventing and improving a new instrument, "L'astrolabe à prisme," "the astrolabe with a prism" or the prismatic astrolabe. Of this, there are several forms, but the principle in all is the same. Like the sextant, the astrolabe involves the use of an artificial horizon, but it replaces the two separate sextant mirrors by a single equilateral glass prism. The prism is mounted, edges horizontal, with rear face vertical, in front of the object glass of a horizontal telescope rotatable on a vertical axis in a horizontal plane, and the whole—prism, telescope, mercury basin and other appliances—is supported on a tripod like a theodolite.

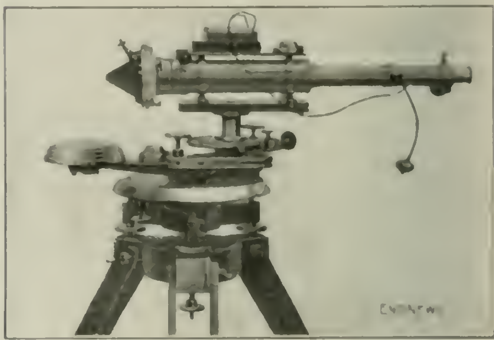


Fig. 2. Prismatic Astrolabe for Determining Latitude and Time by the Method of Equal Altitudes

One face of the prism receives light directly from the star, another from the star's image reflected in the mercury, and the two light rays, after internal reflection, pass through the rear face of the prism to the object glass. Stars are thus observed at a constant altitude of 60°.

For time determination, observations are made in the neighborhood of the prime vertical, where the altitude changes most rapidly; for latitude, near the meridian. As it is easily possible without field illumination to observe stars as faint as the seventh magnitude, a skillful observer may secure 30 to 40 stars in less than an hour, and this number is sufficient to give very good values for both time and latitude.

An interesting feature of the astrolabe is that, unlike other instruments, the results obtained, if the prism be well constructed and by employing reasonable care, are almost entirely independent of errors due to maladjustment. The telescope should be perfectly horizontal; so also should the prism edges; and the rear face of the prism should be vertical. If, however, the prism edges, for example, are not horizontal, the skilled observer will recognize this fact when he perceives the motion of the star in the field of view and a slight touch of a screw eliminates the inconvenience; indeed, this adjustment is generally effected on every star.

The one important adjustment—and even that is not absolutely essential—is the perpendicularity of the rear face of the prism to the axis of the telescope, which is easily effected by aid of a simple accessory device. If the adjustments are not perfect, the only error involved is in the observed altitude which, instead of being 60°, may be some larger or smaller quantity; but if care is taken to make all observations in the same portion of the field and in the same way, this quantity will be the same in all positions of the instrument. All stars will be observed at the same altitude, and the resulting latitude

* [illegible]

and local time will be unaffected. With the newer type of prismatic astrolabe, permitting temporary field illumination, this condition is easily fulfilled.

There are no instrumental constants to be determined, and consequently there are no systematic errors introduced by such constants. There are no circle measures, with the danger of reading and recording them incorrectly. There are no errors of nadir, pointing, thread inclination, pivots, etc., such as affect observations with other instruments. In fact, nearly all constant errors, affecting all observations alike, are eliminated. There is danger of systematic error introduced by the personal equation in noting the times of observation, but almost all other errors are of the accidental class, and may be eliminated by increasing sufficiently the number of observed stars.

The manipulation of the instrument is simple, rapid and easy. The French employ one or two assistants, but a single observer can work just as easily and quickly without aid. Guided by a previously prepared list of stars containing approximate times and azimuths, the observer first sets the telescope in azimuth, then seating himself at the eye end, watches the star and its reflected image enter the field of view from opposite directions. He touches a screw, perhaps, to cause the images to change slightly their relative positions, or to bring their vertical line nearer the center of the field. As the images draw closer in their approach toward each other, he concentrates his attention and at the moment of coincidence makes a record of the time, either by the eye and ear method, or by the chronograph and key. In this record is comprised the whole observation.

The computations both preliminary to and succeeding the observations are long and tedious. An hour's observing list requires many hours of preparation and subsequent computation. The labor of preparing the observing list may be considerably shortened by tables and other aids; and the final computations, too, may be made more easy by tables and graphic processes. The fact, nevertheless, remains that the computations are time consuming. In view of the high precision attainable, this objection should carry but little weight, particularly when it is remembered that the computations may be made at one's leisure, long after the observations have been completed.

The instrument is comparatively inexpensive, it is light and portable, and requires no previously established stable foundation, but may be set up in a few minutes. These considerations should recommend it particularly to geographers, explorers, surveyors and other travelers who seek accuracy, yet do not wish to encumber themselves with the comparatively heavy portable transit and accompanying chronograph. For the very finest kinds of longitude work, however, owing to the personal equation, the astrolabe should be looked upon with suspicion. Yet it should be remarked that it has been used side by side with portable astonomic transits of the best known types, and the results obtained by the two different kinds of instrument have been wonderfully close.

The prismatic astrolabe has been employed by the French on boundary and other survey work in their colonies, in the measurement of a meridian arc in Ecuador, and more recently in important wireless longitude determinations. It was used last spring in the preliminary operations attending the determination of the difference of longitude between Washington and Paris.

The astrolabe may be employed for absolute longitudes by observing equal altitudes of stars and of the moon. It can advantageously replace the portable transit in much of the longitude work now carried on in this country, and would result in considerable saving. Among other applications, it may be employed at fixed observatories to determine star positions. Our astronomers and engineers should give it a trial.

For an exhaustive discussion, the reader is recommended to A. Claude et L. Dueneourt, "Description et Usage de L' Astrolabe à Prisme."

The Twelfth St. Viaduct Accident, St. Louis

Supplementing the account in our last issue (p. 706) of the accident at the Twelfth Street Viaduct in St. Louis, we reproduce herewith a general view of the span affected by the wreck. The span crosses two tracks of the Missouri Pacific Ry., and is 54 ft. long. It consists of reinforced-concrete main beams and transverse slab (the slab reinforcing rods show in the view). Each main beam was supported by 24-in. I-beams resting on pairs of 8x8-in. wooden posts. It is believed that failure of one or more of these posts, possibly from lack of bracing, caused the collapse. Three main beams went down. At the time the photograph was taken, the wreckage had practically all been cleared away. Practically no delay will result. This was the last span of the viaduct to be concreted.

Partial Wreck of Span 16 of Twelfth Street Viaduct, St. Louis, Mo.

(This span crosses Missouri Pacific tracks. Three main beams or stringers of 54-ft. span went down, shortly after being poured, due to failure of the posts supporting the steel centering beams.)

Notes from Engineering Schools

HARVARD UNIVERSITY.—The half course in administration of municipal sanitation given last year has been expanded to a full course to be given three times a week throughout the coming year. The course will not be confined to sanitation but will include city administration, vital statistics, city planning, housing, fire protection, police, lighting and paving. Special outside lecturers will have charge of six exercises each—in order to give adequate treatment of their subjects. The topics are essentially of engineering nature but are to be presented for those who desire to fit themselves for municipal executive and legislative effort.

MICHIGAN COLLEGE OF MINES.—This institution has opened its doors to the practical mining man. Announcement has been made of the introduction this year of a series of special short courses in mining, metallurgy, mapping, drawing, concrete construction and like subjects that will be open to ambitious workingmen. This step has been under consideration for many years and is now introduced as a permanent extension of the college work, designed to broaden its usefulness.

The admission requirements for the new courses are simple. It is required first that a man be able to read and write the English language to a fair degree of proficiency. The second demand is that a man be of good character and have had experience in the mine, mill, smelter, shop, etc.

The courses will run from five to twelve weeks, probably coincident with the regular college work. The same teachers and equipment will be used in this work as in the regular college courses. Every course will be given under the head of the department to which the subject belongs. There has been no attempt to place definite limits on the number of courses or the ground to be covered by them. They are to be arranged to suit the demand. It is intended also to pay particular attention to men who come for special work—whether with previous technical training or not.

NEWS NOTES

Recent Floods in Polk County, Iowa, [illegible]

An Explosion of Natural Gas in a Building Basement [illegible]

A Mine Explosion [illegible]

An Explosion in a Fireworks Factory [illegible]

A Boiler Explosion [illegible]

An Explosion in the Fireworks Factory [illegible]

... the death of the President of the company, H. L. Thearle, and three of the other employees. The explosion took place in the steel and concrete vault in the office building. The explosion is supposed to have been caused by a spark from the electric wiring on which an electrician was at work at the time of the explosion.

A 36-in. Water Main Was Broken by a dredge excavating for the foundations of the Wellington bridge over the Mystic River, in the suburbs of Boston, Mass., on Oct. 3. Reports state that the break was caused by driving a spud through the submerged main. A large quantity of water was lost before the gates could be closed, which required nearly an hour. Soon after the gates were closed the pressure in other parallel mains increased and nearly normal conditions in the suburbs of Charlestown, East Boston, Cambridge, Chelsea and other towns were restored. The main is a part of the Metropolitan Water Board's distribution system.

The New Boylston St. Subway, Boston, Mass., was opened to the public Oct. 3. The new subway cost approximately $4,500,000 and will give rapid transit service to Brookline, Brighton and Allston. Construction was begun in March, 1912.

Statistics of Foreign Trade of the United States for August show an increase in imports of $[illegible] over the same month in 1914, while the exports decreased $[illegible],000. The falling off in exports was entirely in manufactured goods and raw materials for manufacturers' use. The exports of foods remained substantially the same. Much more radical changes will doubtless be shown by the returns for September.

Installation of a 50 Million-Gal. Chlorinating Plant was recently made in 28 minutes at the Watts Pond pumping station, Brooklyn, N. Y. It was desired to disinfect the water supply from this station without delay, and a telephone order was placed with Wallace & Tiernan of New York, makers of treating apparatus for use with liquid chlorine. Two sets were sent out with a set mounted ready for use on a panel board and calibrated so that it had only to be fastened to the station wall and connected to the chlorine tank and water-supply lines.

Improvements on the Chicago, Milwaukee & St. Paul R.R.—During the year 43 steel bridges, aggregating [illegible] ft. in length and 6 masonry bridges, aggregating 676 ft. in length, were built—replacing 3130 ft. of wooden bridges, [illegible]13 ft. of iron bridges and 212 ft. of embankment, and 12,[illegible] ft. of wooden culverts were replaced with iron and concrete pipe. About 3[illegible] miles of pile bridges were filled with earth, 9[illegible] bridges having been completely filled and 7[illegible] reduced in length by filling.—From the company's annual report for the year ending June 30, 1914.

Grade Crossing Elimination on the Chicago, Milwaukee & St. Paul Ry. system is summarized as follows in the annual report of the company. In Minneapolis 37 grade crossings are being removed and the work is about [illegible] completed. In Chicago along the Bloomingdale Road for a distance of 2.[illegible] miles 45 grade crossings are being removed. On the Evanston division work was begun last February on the elimination of 36 grade crossings, a distance of [illegible] miles. In Milwaukee [illegible] grade crossings are being removed. The work will require about two years.

Impulse Wheel for 5412-Ft. Head.—Among the exhibits of the firm of Piccard, Pictet & Co., Geneva, Switzerland, at the Swiss National Exposition being held at Berne, Switzerland, is an impulse wheel built for the Fully high head plant of the [illegible], a French company. This is a horizontal shaft wheel which will develop [illegible] hp. at [illegible] r.p.m. Its wheel diameter is [illegible] ft. and the jet diameter is [illegible] in. The Fully plant (as noted in Engineering News, May [illegible], 1912, p. [illegible]) will be the highest head water power plant in the world by a considerable margin. No [illegible] [illegible] prior to this one.

The Organization of Fraudulent Engineering and Drafting Companies, [illegible]

A Street Extension by Subway or Open Cut [illegible]

West Side Park Commission objects to having the car tracks extended through the park, and in order to meet this objection the Northwest Side Commercial Association has had plans prepared for carrying the tracks either in a covered subway or an open cut, with inclined approaches. These plans, prepared by Wm. W. Marr, have been submitted to the park commission, and the estimated cost is $65,000 for the open cut and $110,000 for the subway.

Elimination of Traffic Congestion at the foot of Market St., San Francisco, is being considered by the city in a plan which contemplates the acquisition of six parcels of land from two city blocks to create a new street two blocks long, 91½ ft wide, parallel to and 137½ ft. south of Market St. The present ferry-bound cars on Market St. would be rerouted through this new avenue of approach to the Embarcadero to prevent the procession of cars there in opposite directions due to the present ferry-loop tracks. The terminals of the Mission, Howard and Fulsom St. lines could be shortened 100 ft. Two foot bridges of structural steel and reinforced concrete would be built, running from the second story of the ferry building over the Embarcadero in the general line of and on either side of Market St., with entrances and exits to give best access to various street-railway lines, sidewalks and ferries. The estimated cost is placed at $380,000 for land, $49,000 for street-railway changes, $59,000 for foot bridges, $15,000 for changes to Ferry Building.

The Railways of Great Britain were taken over for operation by the British Government at the outbreak of the war and are operated as a single system under control of a committee made up of the General Managers of all the principal railway companies. The operation of the railways proceeds as usual, except that the military requirements of the government are paramount to all other traffic considerations. The compensation to be paid to the companies owning the roads for their use will be the net receipts from operations increased by the amount by which the net receipts during the period of government operation may fall short of the net receipts during the corresponding period in 1913. It is provided, however, that where the net receipts of any railway were less in the first half of 1914 than in the corresponding half of 1913 the basis on which compensation is to be computed shall be decreased in like proportion. Under this arrangement the government makes no special payment for transportation of troops or any other service performed for the government, this being paid for under the arrangmeent above noted.

Grade Crossing Elimination in Paterson, N. J. has been investigated by the City Engineer, H. J. Harder. He estimates, in a report to the Finance Commission of the City, on Oct. 1, that to depress the tracks of the New York, Susquehanna & Western would cost $2,772,000, while to elevate the tracks of the Erie would cost $2,587,000. Land damages have not been included in either estimate. The work of depressing the Susquehanna tracks may be divided into four independent sections, any of which may be completed without the others and without the duplication of any work when the other sections are constructed. The average estimated cost is $139 per lin.ft. for the Susquehanna against $142 for the Erie.

The bridges over the streets would be of the through plate girder type with waterproof trough floors. Those carrying the streets over the railroad would be of a similar type, except that where street intersections come on the railroad right-of-way the bridges would probably consist of concrete arches thrown between heavy I-beams extending from one abutment to the other. The Susquehanna right-of-way in most places is wider than that of the Erie, and it will be possible to allow the cuts and fills to run out on natural slopes part of the way. Retaining walls will be required, however, along the greater part of the line. These will be of concrete backed by dry rubble to carry off the drainage.

Street grades on approaches to crossings have in nearly all cases been kept below 4%, in only two or three places reaching 5% and in one instance 6%.

PERSONALS

Mr. Frank M. Williams, M. Am. Soc. C. E., former State Engineer of New York, has been nominated for that office by the Republican Party at the recent primaries.

Mr. Jesse C. Bader has been appointed Manager of the Western Sales Branch of the McMyler Interstate Co., of Cleveland, Ohio, with headquarters at 1503 Fisher Bldg., Chicago, Ill.

Mr. Leslie Warren Goddard, M. Am. Soc. C. E., Principal Assistant Engineer, U. S. Engineer Office, Grand Rapids, Mich., was married Sept. 26 to Miss Mina Etta Bordine, of Saline, Mich.

Mr. Patrick Kierman, for 30 years Superintendent of the Fall River, Mass., water-works, has resigned. He has been a member of the New England Water Works Association for 28 years.

Mr. John A. Bensel, Past-President, Am. Soc. C. E., State Engineer of New York, has been renominated as a candidate for the same office by the Democratic Party at the recent primaries.

Mr. F. J. McKee, who has been Acting Superintendent of Terminals of the Grand Trunk Ry. at Port Huron, Mich., has been promoted to be Superintendent, succeeding Mr. J. F. Jones, resigned on account of ill health.

Mr. Alfred E. Kornfeld, who relinquished his connection with "Engineering News" in 1912 after 18 years' service, has again become identified with it and as a member of its business staff, with headquarters in New York City.

Mr. George P. Johnson has resigned as General Manager of the Chesapeake & Ohio Ry., Richmond, Va., and for the present no successor will be appointed. Mr. Johnson was formerly Receiver for the Detroit, Toledo & Ironton Ry.

Mr. R. F. Peters, M. Am. Soc. M. E., recently Mechanical Engineer of the San Antonio & Aransas Pass Ry., has been appointed Senior Mechanical Engineer, Division of Valuation, Interstate Commerce Commission, with headquarters at Kansas City, Mo.

Mr. T. B. Van Dorn, Vice-President and Engineer of the Van Dorn Iron Works of Cleveland, Ohio, has been elected President, to fill the vacancy caused by the death of his father, the late J. H. Van Dorn, who was the head of the company for 35 years.

Mr. C. M. Cott, formerly with the engineering staff of the McClintic-Marshall Co., of Pittsburgh, Penn., and recently Chief Engineer of the Champion Iron Co., Cleveland, Ohio, has been appointed Manager of the new Cleveland office of the Trussed Concrete Steel Co., of Youngstown, Ohio.

Mr. E. M. Mohrman, recently Superintendent of Construction and Division Engineer of the Twin Falls Land & Water Co., Twin Falls, Idaho, has accepted a position with the Trussed Concrete Steel Co., of Youngstown, Ohio, with headquarters at the newly established offices of the company in Cleveland, Ohio.

Edward J. Kunze, M. Am. Soc. M. E., who for the past four years has been Assistant Professor of Mechanical Engineering in charge of machine design and construction at the Michigan Agricultural College, has been appointed Professor of Mechanical Engineering in charge of the department of mechanical engineering at the Oklahoma Agricultural and Mechanical College.

Mr. T. Coleman du Pont is reported to have abandoned his plans to build a $2,000,000 highway for the state of Delaware because of the opposition which developed against the acquisition of land for right-of-way. The engineering force gathered to build the road, the organization of which was described in "Engineering News" of Jan. 25, 1912, has been disbanded. Mr. du Pont has already spent about $100,000 on the project.

Mr. Thomas D. Pierce, Assoc. M. Am. Soc. C. E., recently Assistant Engineer, Valuation Department, Toledo & Ohio Central Ry., has been appointed Appraisal Engineer of the Public Utilities Commission of Ohio. The appointment was received through a civil service examination, in which Mr. Pierce ranked high. He is a graduate of Case School of Applied Science, Cleveland, Ohio, and has had about ten years experience in railway location and construction, and in appraisal work.

Messrs. J. C. McGormley and J. J. King, formerly of Toledo, Ohio, have formed the McGormley-King Co., with offices at 641 Engineers' Bldg., Cleveland, Ohio. Mr. McGormley was Secretary and Treasurer of the De Vare-McGormley Co., Industrial Engineers of Toledo; and Mr. King was employed in a similar capacity with the Henehan-King Co., General Contractors, also of Toledo. The new firm will specialize in industrial engineering, particularly the design and construction of factory buildings.

Messrs. John Garretson Eadie, Mortimer Freund and James Kenneth Campbell announce that they have established the firm of Eadie, Freund & Campbell, Consulting Engineers, 7 W. 45th St., New York City. The new firm will specialize in the design and supervision of installations for the heating, ventilation, lighting, plumbing, water supply, refrigeration and automatic sprinkling of all classes of build-

[illegible] industrial establishments.

The New York State College of Forestry at Syracuse, N. Y., has added [illegible] Prof. J. Fred [illegible] of the Department of Forestry at [illegible] College, is to take charge of ex[illegible] work in forestry. Mr. [illegible] W. Allen, Deputy [illegible] U. S. Forest Service, a graduate in forestry [illegible] State College, will [illegible] extension [illegible] forestry. Mr. [illegible] C. Adams, recently at the University of Illinois, has been appointed Forest Zoologist. [illegible] L. H. [illegible] University of Michigan, has been appointed [illegible] and Dr. H. [illegible] of Cornell University, has been appointed Forest [illegible]

Mr. [illegible] Whitham, Assoc. M. Am. Soc. C. E., has [illegible] as Chief Engineer of the Port of Seattle to engage in [illegible] practice with offices in the New York Bldg., Seattle, Wash. The Seattle harbor improvements which have cost [illegible] are now practically completed. Mr. Whitham will be associated with Mr. George W. Evans, M. Am. [illegible] Chief of Coal [illegible] U. S. Geological Survey. Mr. Whitham as Chief Engineer of the Seattle Port Commission has [illegible] of the design and construction of [illegible] terminals in the [illegible] Waterway, Central [illegible] and warehouse, the Smith Cove Pier, Salmon Bay [illegible] and the East Waterway [illegible] basin and improvements including a very large grain elevator and cold storage warehouse. Mr. Whitham has previously been Chief Engineer of the Seattle Public Utilities Department, and also Engineer of the [illegible] Port Commission.

Dr. [illegible] J. McLaughlin, Surgeon, United States Public Health Service, has been appointed Commissioner of Health of Massachusetts at a salary [illegible] per annum for a term of [illegible] years. The position is a new one created by a law which went into effect Aug. 6, 1914, abolishing the old State Board of Health, whose executive officer was the Secretary, and establishing a State Department of Health, of which the newly appointed Commissioner is the Chief. The law creating the new department was reprinted in our issue of July [illegible] and commented upon in the editorial columns of [illegible] issue, July [illegible]. Dr. McLaughlin was born in [illegible] June [illegible] 1872. He graduated at the [illegible] in [illegible] and at the [illegible] College of [illegible] in [illegible]. In [illegible] he was appointed Acting Assistant Surgeon [illegible] Public Health and Marine Hospital and was promoted through successive grades to be Surgeon in 1912. He served both in this country and abroad and from 1898 to [illegible] was Acting Director of Health for the Philippine Islands. In [illegible] and [illegible] he was in charge of the federal investigation of sewage pollution of the Great Lakes and the [illegible] and since [illegible] has been Chief Sanitary Expert and Director of [illegible] for the International Joint Commission.

[illegible]

[illegible]

...served with the Lighthouse Service, and during this period he had charge of construction of several large lighthouses on the Gulf Coast, among them the [illegible] Light, which is a difficult structure some [illegible] miles from shore, presenting many difficulties in construction.

A. Considère, Inspector General, retired, of the Ponts et Chaussées of France, has just died at the age of 72. M. Considère was probably better known in America than any other continental European engineer, particularly in the field of testing materials and of concrete. A large part of his professional career was spent at Quimper, where, while serving as an engineer in his corps, he devoted so much attention to the testing of materials. He was one of the earliest of modern engineers to investigate thoroughly the properties of concrete, and particularly of reinforced concrete. In 18[illegible] Considère published the results of his researches on mortars, concretes and reinforcement, a book which immediately took its place as the foremost exposition of the subject. It was as a result of his investigation published at this time that he announced the well known theory that the conjunction of steel and concrete gave to each of the two materials certain properties which separately they did not possess. This theory was accepted by the scientific world for a number of years but was later disproved by the famous [illegible] tests at the University of Wisconsin. Considère's name is also connected with another radical development in reinforced concrete, namely, the hooped column, which he devised some years ago. He was a prominent member of the International Association for Testing Materials and was prominently spoken of for the presidency of the International Commission on reinforced concrete established in 190[illegible]. Since his retirement, some years ago, M. Considère has been at the head of a bureau for testing materials which he established in Paris.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN ELECTRIC RAILWAY ASSOCIATION.
Oct. 12-16. Annual convention at Atlantic City, N. J. Secy., E. B. Burritt, 29 West 39th St., New York City.

NATIONAL COUNCIL FOR INDUSTRIAL SAFETY.
Oct. 13-15. Annual Safety Congress at Chicago, Ill. Secy., W. H. Cameron, Continental [illegible] Building, Chicago.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.
Oct. 20-22. Convention at Los Angeles, Calif. Secy., C. A. Lichty, 319 North Waller Ave., Chicago, Ill.

INTERNATIONAL ASSOCIATION OF FIRE ENGINEERS.
Oct. [illegible] Annual convention at New Orleans. Secy., James McFall, Roanoke, Va.

AMERICAN GAS INSTITUTE.
Oct. [illegible] Annual meeting in New York. Secy., George G. Ramsdell, [illegible] W. [illegible] St., New York City.

NORTHWESTERN ROAD CONGRESS.

VOLUME 72 | OCTOBER 15, 1914 | NUMBER 16

Palace of Horticulture and Dome, Panama Pacific Exposition

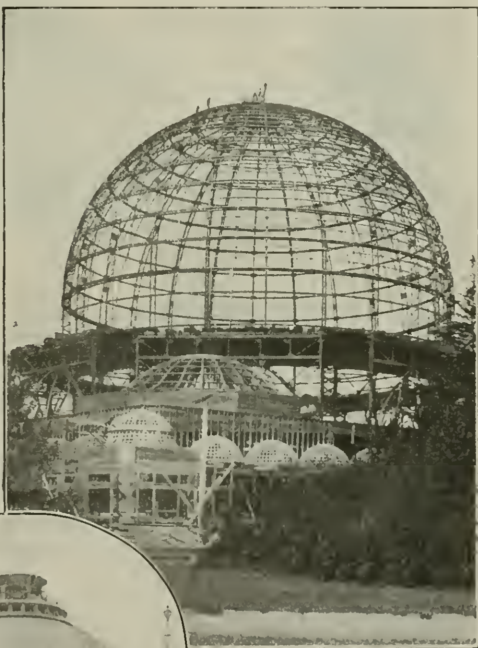
By A. W. Earl and Thomas F. Chace*

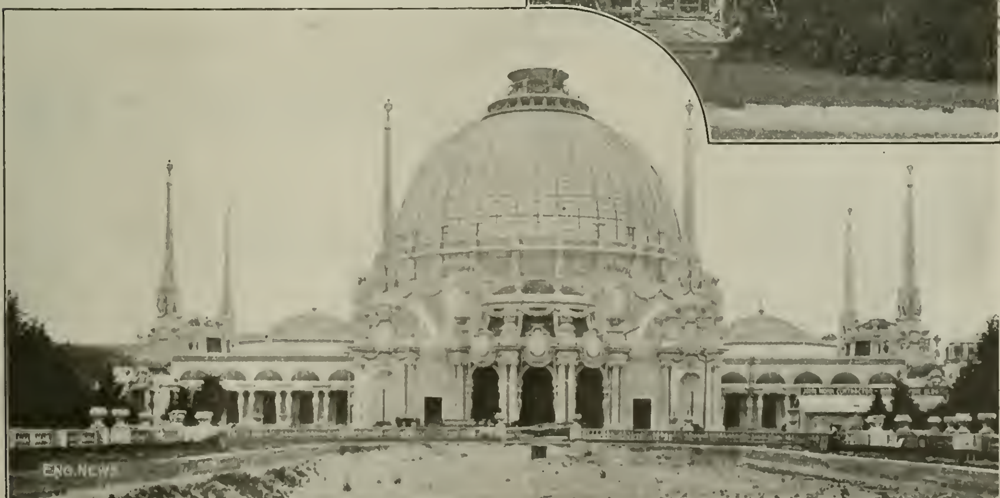
The recently completed Palace of Horticulture at the Panama-Pacific Exposition has a dome that ranks among the largest steel domes and in fact among the largest domes of any kind in the world. The size of this structure, coupled with a desire to keep the framework light and airy in conformity with the character of the building, made a careful study of the design well worth while. Many interesting problems arose in the course of this study. The character of the framing and the methods of analysis by which the designs were worked out will be set forth in future articles by the authors. For the present a brief description of the building is given.

The Palace of Horticulture is rectangular in plan, approximately 660x300 ft., and covers an area of 4½ acres.

The eastern or main portion is square in plan and forms the base for the imposing glass-covered dome, the salient feature of the design. The dome is a hemisphere 152 ft. in diameter, resting upon a cylinder of the same diameter and 25 ft. high. It is surmounted by an architectural staff motive in the form of an immense flower basket. The extreme height from the ground to the top of the basket is 186 ft. Rising from the low roof and intersecting the large dome are eight small glazed half-domes, and at the four corners of the square are four octagonal domes of timber construction. The main entrances on the north, east and south sides are accentuated by elliptical domes built of wooden lattice-work. On either

*Asst. Structural Engineers, Panama-Pacific International Exposition, San Francisco, Calif.



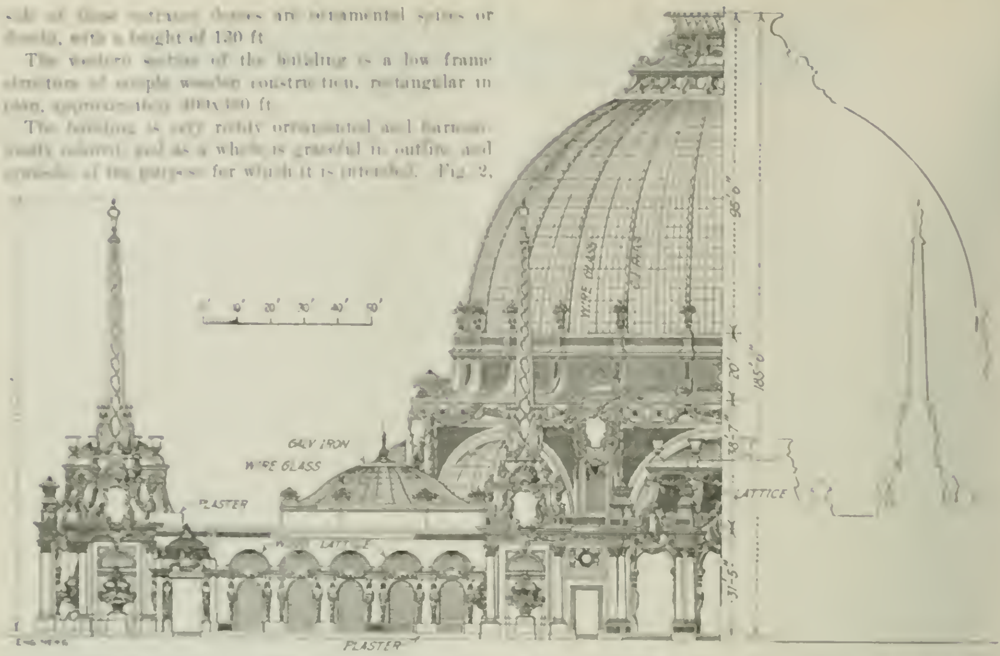


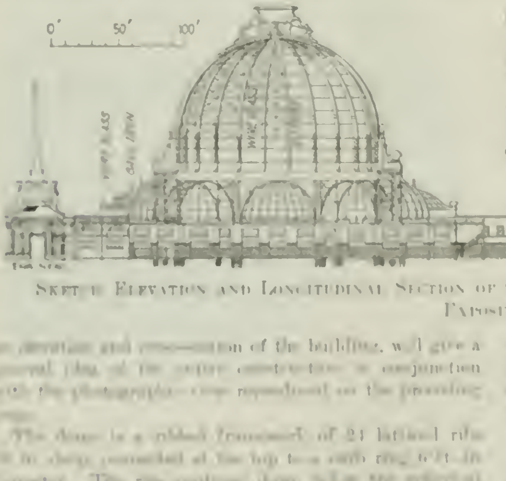
The Palace of Horticulture of the Panama-Pacific International Exposition at San Francisco
(The great glass-covered dome, 152 ft. in diameter, has a steel frame, but the rest of the building is largely wood-framed.)

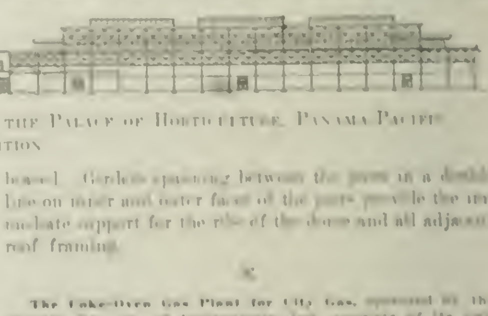
side of these entrance domes are ornamental spires or domes, with a height of 130 ft.

The western section of the building is a low frame structure of simple wooden construction, rectangular in plan, approximately 400x180 ft.

The building is very richly ornamented and harmoniously colored, and as a whole is graceful in outline and symbolic of the purpose for which it is intended. Fig. 2, an elevation and cross-section of the building, will give a general idea of the entire construction in conjunction with the photographs reproduced on the preceding page.







SKETCH ELEVATION AND LONGITUDINAL SECTION OF THE PALACE OF HORTICULTURE, PANAMA-PACIFIC EXPOSITION

The dome is a ribbed framework of 24 latticed ribs 36 in. deep, connected at the top to a crown ring 6 ft. in diameter. The ribs continue down below the spherical part as straight vertical members a distance of 23 ft. The dome is, however, [illegible] at the springing line of the dome by a [illegible] horizontal tie ring. At the foot of the vertical portion of the rib no thrust is taken; the ribs rest simply on girders.

The main ribs are connected by 11 horizontal lattice girder rings. These act both as tension rings and as main purlins, carrying secondary ribs or rafters of 4-in. I-beams, on which rest wooden purlins supporting the skylight bars. Adjustable diagonal rods brace all panels between ribs and rings.

The total weight of steel in the dome, above the plate-girder supports of the ribs is 300 tons.

The dome is carried by eight piers 65 ft. high above ground level. Each of these consist of four columns braced in trapezoidal arrangement, 4 ft. 6 in. apart on the inner face, sides diverging at an angle of 45°, and 15 ft. 10 in. deep in a direction radial to the dome. On the diverging side the pier bracing extends only down to a height of 14 ft. 7 in. from the floor, where a passageway occupies the clearance. Except for this the pier is fully braced. Girders spanning between the piers in a double line on inner and outer faces of the piers provide the immediate support for the ribs of the dome and all adjacent roof framing.

The Coke-Oven Gas Plant for City Gas, operated by the Citizens Gas Co., of Indianapolis, Ind., consists of its new plant of 100 by-product coke ovens [illegible] and a second plant [illegible]. The total carbonizing capacity is [illegible] tons per day respectively. The old water-gas and coal gas plants of the Indianapolis Gas Co. (now controlled by the Citizens Gas Co.) were operated for a time, but since March, 1914, only coke-oven gas has been produced. During the first half of 1914, the total coal carbonized was [illegible] tons, with a production of [illegible] tons of coke, all of which has been sold, while the output for the remainder of the year has been sold also. The sale of the by-products has been satisfactory. The production of gas (exclusive of that used for oven heating) was as follows: Coke-oven gas, [illegible] cu.ft.; water-gas, [illegible] cu.ft. and coal gas, [illegible] cu.ft. Of the total [illegible] cu.ft., about [illegible] cu.ft. were used under boilers and [illegible] cu.ft. were sold to consumers. The average heat value was [illegible] B.t.u. for the gas from the [illegible] plant and [illegible] B.t.u. for that from the [illegible] plant.

Gravel-Road Construction in Wisconsin

Wisconsin is one of the states in which gravel is plentiful and has been used extensively for road construction, and under the present system of state aid and supervision in highway work a considerable amount of work is being done in the construction and improvement of gravel roads. For information as to this work we are indebted to A. R. Hirst, State Highway Engineer (at Madison), and W. M. de Berard, District Engineer (at Milwaukee).

The old practice in building such roads was to dump loose gravel, to be consolidated and worn down by traffic. The road was then neglected entirely until certain parts were practically destroyed, when holes and low spots would be filled with loose gravel deposited in the same way and usually in excessive quantities. Traffic would keep to the sides of these mounds of gravel, gradually forming a new roadbed and making eventually a very irregular line of road. One of the lines of work of the Wisconsin Highway Commission is to secure the proper use of this excellent material, and the proper maintenance of the roads built with it. The old road makes an excellent foundation for the new surface.

It is not always easy to secure the necessary coöperation of the local authorities or to make them realize that they are spending much more in this ineffective repair work than would be required for the proper reconstruction of the roads.

There has been a little difficulty also in initiating the construction and improvement of gravel roads by the Highway Commission, due to a general feeling in the rural districts that they needed no instruction in making roads of gravel. There was an impression also, that as Wisconsin has an abundance of limestone quarries the state authorities would substitute stone for gravel and thus greatly increase the cost, to the benefit of the stone companies. However, these latent suspicions are disappearing, as it is now being realized that it is the endeavor of the Commission to use local material where possible, and to combine strict economy and good work in all its road work.

Use of Varying Qualities of Gravel

While gravel exists in large quantities and over a large area of the state, it is of very varying character, requiring different methods of treatment to adapt it for making good roads. Practically no two gravels are alike, even though obtained from neighboring pits. For this reason it is required that deposits proposed to be used by local authorities on state-aid roads must be examined and approved by the engineers of the Commission.

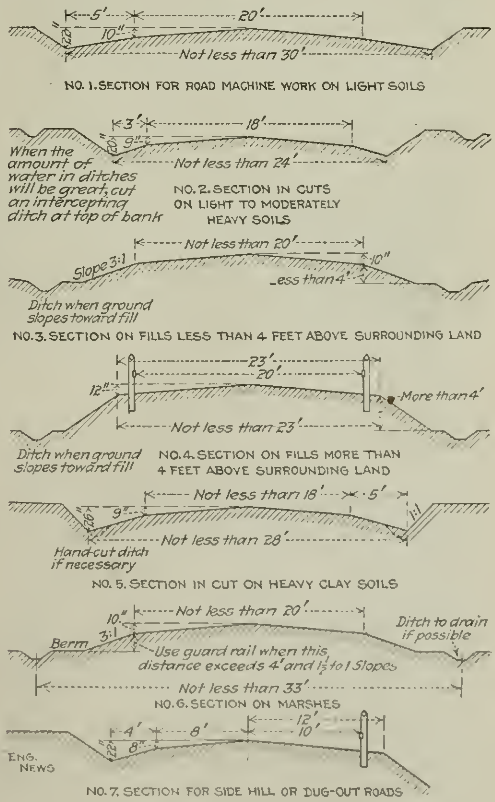
In certain cases the material is of such size and of such cementing character that the pit-run gravel can be put directly into the road. As a rule, however, it contains stones too large for use in the surface course, so that crushing and screening are necessary. Many deposits have too large a proportion of sand, while the sand is of a non-cementing character. In such cases the addition of clay as a binder may easily make the material suitable for use. In some locations washed gravel (prepared for concrete use) is available, and may be rendered satisfactory by the addition of clay and limestone screenings.

The gravel stones are usually very hard, and a gravel road is, therefore, more durable than one built with limestone or shaly stone, although local authorities may be inclined to prefer the latter on the general assumption that a "stone road" is a "hard road." Another favorable property of the gravel road is that it tends to wear evenly, and is much less liable to develop the holes and low spots which give a very rough riding surface to a partly worn road of soft stone. At the same time the gravel road is much less dusty. It is also less costly, even from the point of maintenance, as ordinary traffic suffices to compact loose gravel used to repair ruts and holes, if care is taken to select gravel having a percentage of clay or being of a cementing quality.

The width of road surface is 18 to 20 ft., with a 9-ft. graveled surface and 5 ft. shoulder on each side. On main roads with heavy traffic the graveled width is 18 ft. The form of roadbed used under different conditions is shown in the accompanying cut; these sections apply to finished gravel and macadam roads with 9-ft. surface, and also to earth roads. It will be noticed that with fills of over 4 ft. in height a post-and-rail fence is used for the protection of traffic. In some cases deviations or cutoffs are made to eliminate steep grades. Land may be condemned for these purposes, and the abandoned roadbed then reverts to the owner of the adjacent land.

Road Construction with Crushed Gravel

A majority of the gravel road work is done with



Standard Cross-Sections for Gravel, Macadam and Earth Roads in Wisconsin (with Gravel or Macadam Surface 9 Ft. Wide)

crushed gravel. The crushing and screening are done at the pit, which is selected as near as possible to the work, and a portable plant is used, since the jobs are usually short ($1\frac{1}{2}$ miles to 2 miles). One plant, which in many respects is typical, may be described as follows.

The gravel formed a small hill, with practically no stripping beyond the removal of sod, and was excavated by two or three wheeled scrapers working over a circular surface on the slope. At the lower side of the path the gravel was deposited beside a platform, beneath which was the portable crusher, of jaw type, adjusted for a product of $\frac{1}{2}$ to $3\frac{1}{2}$-in. size. A team at the lower level, on which the crusher stood, moved to and fro, pulling a slip scraper crosswise of the pile of material dumped from the wheel scrapers, and delivering it to the hopper of the crusher. A length of cable led from the team to the scraper.

An elevating conveyor raised the product to a three-size revolving screen, grading the material into screenings, $\frac{1}{2}$- to 2-in. stone, and 2- to $3\frac{1}{2}$-in. stone. In order to have a proper proportion of fine material, a part of the "screenings" section of the screen was wrapped with felt or sheet iron, so that both fine and coarse material would travel along to the coarse end of the screen. The crusher, elevator and screen were driven from a 20-hp. traction engine. The screen was over a three-compartment storage bin, with side chutes for loading the wagons.

From two to four drop-bottom dump wagons were used to convey the material to the road, according to the length of haul. The coarse material for the lower layer was dumped on a carefully prepared subgrade and was spread with rakes to a thickness of from 5 to 6 in. (seldom less than 4 in.), depending on the character of base soil or subgrade. Screenings or clay was then applied to prevent creeping under the roller and to secure good compaction, as the binding of the second course takes place over the same, and with much better ease. This latter course was placed in the same way, to a depth of from 4 to 5 in. (seldom less than 3 in.), rolled dry, meanwhile screenings were spread until all the stone was covered. Then it was sprinkled and rolled thoroughly, giving the road a finished thickness of from 6 to 8 in., dependent on the depth of [illegible] placed.

An average force for such a job as described above would be about as given in the accompanying list: One foreman, one engineman, one helper, two or three men with wheeled-scraper teams (or wheelbarrows), two men with slip-scraper team, [illegible], two to four men with dump wagons, one team [illegible] screenings, one roller driver, one tank wagon driver, and water boy.

In another case, no scrapers were used, but three men at the pit [illegible] the gravel into wheelbarrows which an equal number of men wheeled to the crusher on planks [illegible]. These crews work six 10-hour days per week.

Such a force as [illegible] will build about [illegible] ft. of road per week, depending upon the amount of grading and finishing work to be done. The cost of the gravel at the pit is usually about [illegible] per cu.yd. The cost of gravel roads built in this way averages [illegible] per sq.yd., which includes the grading of [illegible] and [illegible] culverts (all of which are of concrete).

In some localities good bonding gravels are scarce, but sandy gravels are available. These latter may be adapted for the purpose by the application of clay binder, suitable clay being generally found near the site. The best clay is that which breaks up into almost granular form, so that it mixes thoroughly with the gravel. The lower course is deposited, the clay spread and worked in as evenly as possible, and rolled. A manure spreader has been used to advantage in cutting and spreading the clay, and a farm drag or pulverizer in working it upon the road surface. The top course is then applied, rolled dry and covered with screenings; then thoroughly wetted and rolled until the clay is brought to the surface, after which it is left to dry out. At times a light application of sand or limestone screenings is applied to prevent the surface from picking up in case of rerolling and future travel.

It is considered advisable to oil the gravel roads when funds permit, and to do this the first year on roads subject to heavy traffic or those built early in the season, instead of allowing the road to wear for a year before this treatment.

Machinery

Each county has its own equipment, purchased usually by a committee of the county board, and generally in accordance with the advice or suggestion of the district engineer. The outfit includes road plows and graders, wheel and slip scrapers, water-sprinkling wagons, steam or gasoline rollers (10-ton usually), crushing and screening plant, and sometimes an oil-sprinkling wagon. In some cases farm dump wagons with flat bottoms are used, but where the money can be afforded the drop-bottom wagons are preferred. There is a tendency to use small water wagons with the result that there is often difficulty in keeping the work well sprinkled at the proper time. A 400-gal. tank is very generally used, but a 600-gal. tank is considered preferable and could be handled as easily on the work.

Organization

A brief description of the organization of the Wisconsin State-aid road work was given in ENGINEERING NEWS, June 25, p. 1319. The State Highway Commission has nothing to do with roads outside of this system. A township desiring the improvement of a road within its boundaries, with State aid, must vote an appropriation (not less than $400), the county and state then appropriate equal amounts, making a minimum of $1200 for the work in the township. The state-aid system of roads throughout the state is divided into seven districts, each of which is in charge of a district engineer of the Commission. These men spend most of their time visiting the various jobs, keeping in close touch with the county highway commissioners and with the foremen in direct charge of the work.

This system of organization, whereby the local authorities initiate a piece of work and the local county highway commissioner takes the responsibility for its successful completion under the general supervision and advice of the State Highway Engineer and his assistants, has the advantage of establishing close and friendly relations between the local authorities and the State Highway Commission, avoiding jealousy or antagonism which may arise where the local authorities or the men on the work get the idea that the Commission is simply a set of officials issuing orders from an office in the capital.

An exact and reliable record of cost is essential, so that the local authorities may be informed as to the detailed

of their money. The foreman makes daily report on a printed blank as to his force and work, and makes also a weekly report which shows his payroll. In this way he sees how his money is holding out in relation to the work to be done. These reports are given to the road commissioner, and at the end of the season a summarized cost report is made to the district (state) engineer, who measures up the work and (if it has been done according to the prescribed plans and methods) accepts the road for the state, with recommendation as to whether it should be turned over to the county for maintenance.

This being done, the county is required (under the law) to provide a continuing fund for the inspection and maintenance of the road. This maintenance then comes under the supervision of the district engineer, so that the new road will not be subject to injury by neglect or by the dumping of wagon loads of loose material for "repairs."

The system has worked very well in the short time it has been in operation, and the rural public generally has recognized its value. Thus there is a decline from the old sentiment that while the state should provide money the local authorities should have the spending of it, free from any state supervision.

Most of the road work is done by day labor, as the individual jobs are too small to pay a contractor to put his plant on them, and he could not be sure of getting a sufficient number of jobs to make the work worth while. The concrete road work, however, is done mainly by contract, although in Milwaukee County the county board has its own equipment and builds a large amount of concrete roads.

A New Medal to be awarded to those workers in physical science or technology, whose efforts have done most to advance the knowledge of physical science or its applications, has been established by the Franklin Institute through the gift of $6000 by Samuel Insull, of Chicago. The medal is to be known as "The Franklin Medal" and is to be made of gold of an intrinsic value of about $75. In case the income from the endowment creating the medal should be more than sufficient for the purchase of the medals, the medal may be accompanied by a premium to the recipient.

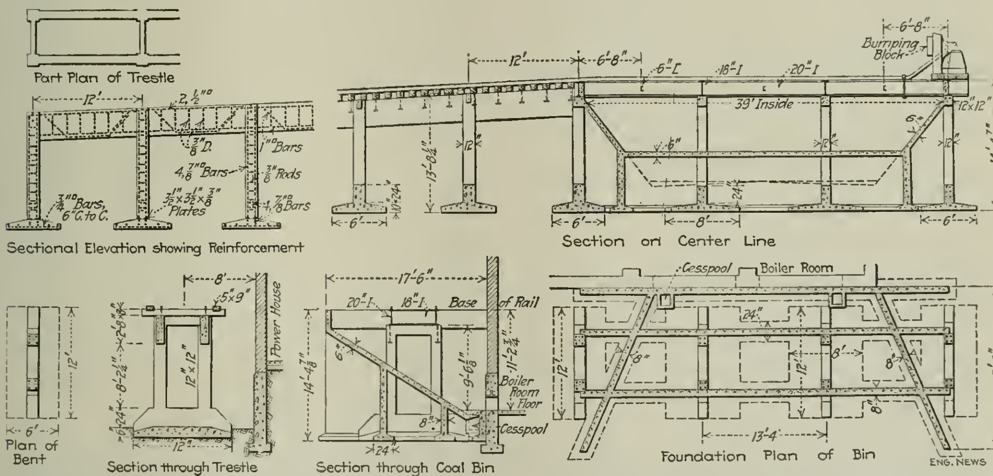
Concrete Trestle and Coal Bin

A coal bin and inclined trestle approach of reinforced concrete is an interesting feature of the new tie-treating plant of the Louisville & Nashville R.R. at Guthrie, Ky. The construction is shown in the accompanying cut.

The bin is alongside the boiler house, and is of hopper shape, with the ends and one side inclined. The other side is open to the boiler house, and the bottom slopes to the level of the floor so that coal is handled directly to the boilers. Its sides and ends are supported by a framing of longitudinal and transverse concrete walls, having broad footings on the red clay soil. The ends and two intermediate concrete bents support a pair of track stringers of 20-in. I-beams, between which are framed 18-in. I-beams and 6-in. channels. Upon the stringers are bolted the track rails. This open construction provides for free flow of the coal from hopper cars. The bin has a capacity of about 100 tons.

The approach trestle is on a grade of 4%. It is composed of a pair of 10x32-in. girders in 12-ft. spans between concrete bents. Each bent has a broad footing 12x6 ft., with two 12x12-in. posts, the posts being connected by a cross wall at the bottom and a strut at the top. All of this is a monolithic concrete structure, as shown at the left of the cut. Anchor bolts embedded in the girders for securing alternate ties provide against movement of the track on the incline. The ties are 8x8 in., 9 ft. long, laid directly upon the girders, and carry outside guard timbers 5x9 in.

The work was done under the direction of W. H. Courtenay, Chief Engineer, and J. B. Lindsey, Superintendent of Timber Treating Plants.



Reinforced-Concrete Coal Bin and Trestle at Guthrie, Ky.; Louisville & Nashville R.R.

The Natural-Gas Gasoline Industry in this country has become of importance in the last three years. The production in 1913 amounted to 24,060,817 gal. valued at $2,458,443, an average price of 10.22c. per gal. as compared with a production of 12,081,179 gal. valued at $1,157,476, in 1912, and 7,425,839 gallons, valued at $531,704, in 1911. In 1913, West Virginia produced 7,662,493 gal., Oklahoma, 6,462,968; Pennsylvania, 3,680,096; California, 3,460,747; Ohio, 2,072,687; the balance was produced by Illinois, Colorado, New York, Kentucky, and Kansas.

Protecting Steelwork Against Locomotive Blasts

One of the greatest problems in the design of steel grade-crossing bridges is the protection of the floor systems and lower chords against the sand blast action of the locomotive exhaust and the corrosive effect of the locomotive gases. The requirements of grade are practically always such that the clearance above the locomotive stack is very small (in some well known instances less than 12 in.), so that the locomotive blast plays directly on the lower part of the bridge, and if it be not thoroughly protected, causes its very early destruction. In the cities of Buffalo and Cleveland, a great amount

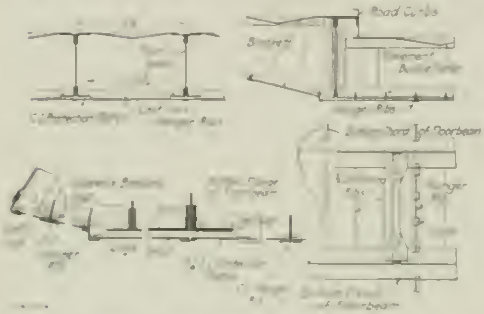


Fig. 1. Methods of Protecting the Under Side of Street Bridges against Locomotive Blasts

([illegible] Robert J. Reidpath & Son for the [illegible] Viaduct, Buffalo, N. Y.)

of grade-crossing work has been done, and a number of different methods of protecting the lower parts of the steel bridges have been tried.

In 1913, Robert J. Reidpath & Son, consulting engineers, made a report to the city of Buffalo on the condition of a number of the steel overhead grade-crossing bridges in that city. They found that a great number had been seriously affected by the locomotive blast and described their condition in the following paragraphs, which indicate the extent of such action:

[illegible]

where the locomotives are operated most frequently in switching, etc.

The trusses and floor-beams are eaten away in places where the [illegible] protection has been forced off by the action of the blast from the locomotives exhausting and by [illegible] chunks of this concrete varying in weight up to twenty-five pounds are [illegible] daily and endangering the lives of the [illegible] working below.

In the [illegible] St. Bridges, over the Pennsylvania, New York Central and Lake Shore tracks and the Hamburg St. Bridge over the same, the steelwork above the lower chords and the floor system is in fairly good condition although there is quite an accumulation of rust that should be removed and the steel painted.

The floor systems are in a very bad condition. The most important members, those supporting the ends of the floor-beams and their loads, will not last but a little while longer and are liable to fail at any time under an unusual load suddenly applied. Originally the steel in the flanges in these girders was [illegible]-in. thick. In some places nothing is left; in other places where it is not entirely gone it varies in thickness from [illegible]-in. up to [illegible] original thickness according to location. The webs of these girders were [illegible]-in. thick; they are now only [illegible] in. thick.

Many of the steel cantilever brackets that support the sidewalks are eaten away to such an extent that in places there is no steel left and what remains is only [illegible]-in. thick.

The flange angles of the floor-beams when built were [illegible] in. thick, many of them have been eaten away until there is only [illegible]-in. of metal left and in some places only [illegible]-in.

The short plate girders between the floor-beams over which the tracks of the street car [illegible] are laid, are in many instances almost eaten away. The web plates were originally [illegible]-in. thick, they are now less than [illegible]-in. thick. In some places one-half [illegible] of the flange angles are gone.

The [illegible] bottom chords of these structures were cleaned and painted in 1911-12; previous to that they suffered severely from corrosion and the effects of gas and smoke from the locomotives. Where they are subjected to the direct action of the exhaust from the locomotives, the paint is [illegible] and they are again badly rusted.

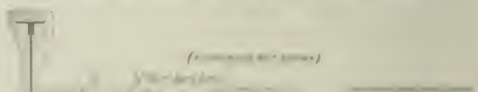

Fig. 2. Cast-Iron Plate Protection, Quincy Ave. Grade Crossing, Cleveland, Ohio

[illegible]

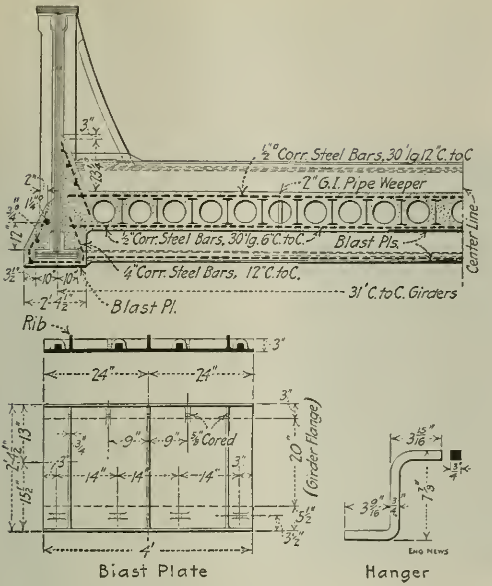

Fig. 3. Cast-Iron Blast Plate on Cleveland Short Line-Nickel Plate Grade Crossing, Cleveland, O.

many years, but the floor systems and parts of the lower chords and several of the piers and abutments must be rebuilt. In doing so, proper precautions should be taken to prevent the gases and smoke from the locomotives injuring them. The natural corrosion can be almost entirely prevented by properly and frequently painting them after they are once more cleaned.

This report indicates that there was a deplorable lack of inspection and maintenance in all of the structures mentioned, which accounts for the serious deterioration they suffered, but at the same time it is evident that the lower parts of the bridges, subjected to the locomotive blast, were affected more than the remainder of the structure.

To guard against this action, the several methods noted below have been tried:

Cast-Iron Plates—It is generally conceded that cast-iron plates withstand the sand-blast action of the exhaust as well as, or better than, any other material, but they are needed only in the path of the locomotive stack. A durable coating, light in weight, which possesses qualities of protecting portions of the structure adjacent to the tracks and between them against injury from steam and gas must be found if the cost of separating grades by carrying the streets over the railroads on long viaducts is to be kept down to what the city and railroads can afford to pay. The method of encasing or embedding the steel-floor system in concrete with cast-iron plates to take the sand-blast action is positive, but it adds considerably to the cost.

A very good example of the cast-iron plate protection is shown in Fig. 1, which is the viaduct across the New York Central, West Shore, and Erie railroads at Chicago St., Buffalo, one of the first crossings to be eliminated. This was closed to all traffic a shore time ago because of its dangerous condition, and to permit extensive repairs, consisting of reinforcing or replacing members damaged principally by locomotive exhaust. Reconstruction plans include the placing of a ceiling of cast-iron plates over the tracks according to design by Robert J. Reidpath & Son. It will be noticed that the lugs and hanger ribs as well as the plates are of cast-iron. Inasmuch as it will be difficult to inspect the steel after the plates are up, penetration of the gases through the interstices between them will be prevented by plastering them on the back with cement mortar. One thought was to fill the interstices with lead and oil.

Fig. 2 shows the method of applying cast-iron plates to the base of the concrete incasement of the girders in the Quincy Ave. grade crossing of the Nickel Plate R.R. in Cleveland. Here the minimum clearance is 16 ft. 3

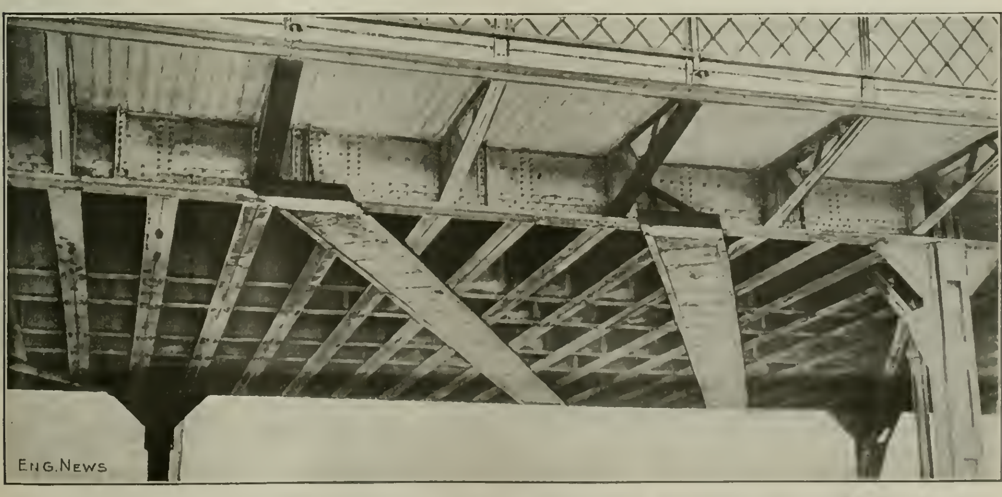

Fig. 4. Under Floor of Hamburg Turnpike Viaduct, Buffalo, N. Y., Showing Cast-Iron Blast Plates and Cement Grout over Red-Lead Oil Paint

in. To incase in concrete each floor-beam, which are about 3 ft. c. to c., on this bridge, required expensive forms and great care in placing concrete. The mix was quite wet in order that it would run from above and completely fill the form around the lower flange. Silica gravel, such as is used to finish parkways, was used instead of crushed stone for the aggregate.

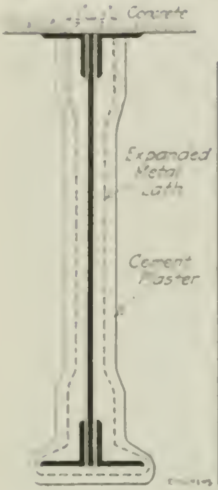

Fig. 5 Fig. 6

Figs. 5-6. Elk St. Viaduct over Railways, Buffalo, N. Y.

Fig. 5. Detail of floor beam showing concrete protection. Fig. 6. Underside of floor after concrete was removed. Cement mortar fell from dark spots. Light areas where concrete was taken off for safety.

Fig. 9 gives the details of the cast-iron protection plates on the Nickel Plate-Cleveland Short Line crossing at Cleveland.

Another instance of this cast-iron locomotive protection plate is shown in Fig. 4, which is the Hamburg Turnpike viaduct over the Buffalo Creek R.R., at Buffalo. Here, cast-iron plates carried by cast-iron hangers resting on the lower flanges of the floor-beams take the blast from the locomotive exhaust.

CONCRETE COATING.—One of the most popular methods of protection is to plaster a cement mortar coat directly onto the lower part of the floor girders, generally holding it on with a wire mesh or expanded metal reinforcement. This gives fair protection under certain circumstances, when the concrete is thick enough or the reinforcement far enough from the surface, but there have been some places where it has failed. Figs. 5-6, which show the Elk St. viaduct over a number of railways in Buffalo, illustrate one such case. About six years ago, floor-beams and stringers of this structure were incased in thick cement mortar plastered on expanded metal lath. It served its purpose fairly well for a time except over the center line of tracks, where it was rapidly cut away. Recently, the concrete protection began to fall in chunks from the lower flanges of the floor beams, endangering traffic and men passing beneath, and, at the request of the railroads, the city removed the portion from beneath the lower flanges.

The weak point was at the outer edge of the lower flange of the floor-beams, with which the metal lath was left in contact during construction. No space was left between the lath and the edges of the angles, with the result that rusting set up and destroyed the lath. Vibration, due to trains passing beneath and traffic overhead, broke the plaster at these lines of contact. The gases appeared to have no effect on the plaster other than to darken it about 1/4 in. deep. If the reinforcement were a little sturdier, and care were exercised to have it bedded in the mortar, this method of protection, in combination with cast-iron plates over the center of the tracks, would give satisfaction.

PAINT AND CEMENT COATING.—As noted above, that part of the floor not directly subjected to the sand blast usually requires some minor protection. A novel method of thus coating steel, applicable both to new structures and to old ones where no protection has been attempted other than painting, has been in use in Buffalo for a number of years. In principle, it combines in an inexpensive manner the properties of protection belonging to both paint and cement.

After the steel is erected, a coat of red lead and oil is applied, mixed in the proportions of 25 lb. of red lead to each gallon of linseed oil. While the paint is still wet, lake sand is thrown against it, so that the grains are embedded about half their diameter in the paint. After it is thoroughly dried, two coats of cement grout, creamy in consistency, and mixed in the proportions of one part of lake sand to one part of cement, are applied with brushes. The Hamburg Turnpike viaduct, shown in Fig. 4, has been treated in this fashion, outside of the cast iron plates over the track centers.

Costs of applying the sand blast and cement grout coats to the paint have not been kept separately, as the

Fig. 7

Fig. 8

Fig. 7. [illegible] Viaduct over Railways, Buffalo, N. Y. Fig. 8. [illegible] Beam Locomotive Blast Protection, [illegible] St. [illegible] Crossing, Buffalo, N. Y.

work was included in general specifications covering an entire job. Thus, at the Hamburg Turnpike, the contractor erecting the steel painted it and applied the cement grout. It is probable that the cement gun could be used to advantage to apply both the sand binder and the grout, guarding against getting the latter too thick.

On the Hamburg St. viaduct (distinct from Hamburg Turnpike), over the Erie, Pennsylvania, and New York Central railroads at Buffalo, the grout has been doing service for four years and is in good condition except over the tracks, no special provision being made to care for the sand-blast action. The method of combining paint and grout in a protective coating was originated by Capt. George H. Norton, deputy engineer commissioner.

Wood and Asbestos Boards—Another method of protection tried out was to ceil the underside of the viaduct with tongue and grooved boards nailed to 1x3-in. strips bolted to wood 3x3-in. hanger ribs resting on the lower floor-beam angles (Fig. 7). The boards shrunk in the dry summer months, admitting gases through the cracks. During the rest of the year they swelled so that the ceiling bulged and had to be taken down to keep it from falling on trains and men.

Still another method was to attach 1/4-in. asbestos lumber by means of 3/4-in. oak plugs to the under side of concrete encasing girders or floor beams. This method was first designed for the Amherst St. bridge over the New York Central R.R., at Buffalo, in 1908. A detail is shown in Fig. 8. This has been satisfactory except after several years the oak plugs become loose.

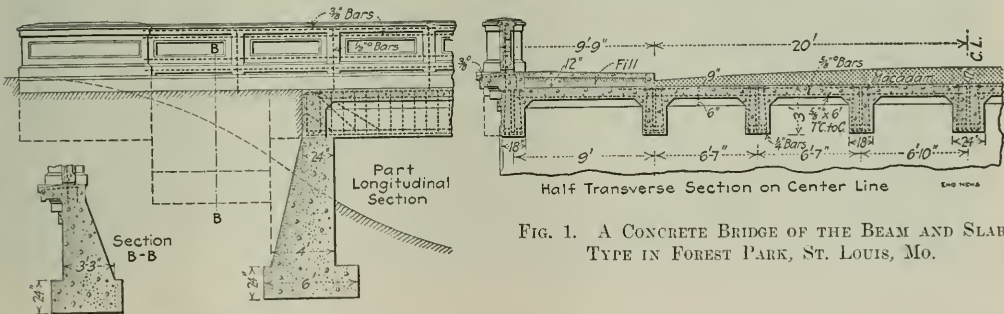

Fig. 1. A Concrete Bridge of the Beam and Slab Type in Forest Park, St. Louis, Mo.

A Park Bridge of Reinforced Concrete

Among the various engineering works for the improvement of Forest Park, at St. Louis, is a reinforced-concrete bridge carrying a main driveway over a storm-water channel. The clear span is 30 ft. and the length over parapet walls is 60 ft. The bridge has a 40-ft. roadway and two 9-ft. sidewalks. It is designed to carry a 10-ton steam roller and a load of 100 lb. per sq.ft. The bridge is of the beam and slab type, with nine beams 3 ft. deep (including the 9-in. slab). The concrete is a 1 : 3 : 4 mixture, made with broken stone, and the reinforcement is of deformed bars. The abutments and the side walls of the approaches are of gravity section.

A rough stucco finish was applied to the exterior, the forms being removed 14 days after the concrete was poured and the stucco coat (1 : 2) then plastered on a scratch coat over the concrete. This surface is relieved by a smooth brush finish for the concrete of the coping, string course, the panel moldings on the end pedestals, and the moldings of the open panels in the parapet wall. The contrast of the rough gray stucco with the smooth and lighter-colored concrete is very effective.

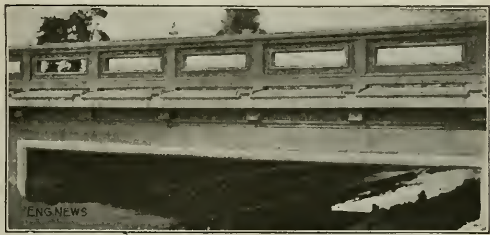

Fig. 2. Exterior Finish of the Park Bridge

(The darker part of the surface is a rough stucco; the coping, paneling, etc., are of smooth brush-finished concrete.)

The architectural details for the bridge were prepared by Geo. E. Kessler & Co., landscape architects, and the structural details by W. S. Will, of the Park Department of St. Louis. The bridge was built by the park forces under Nelson Cunliff, Superintendent of Construction, at a total cost of $4300.

The policy of the department is to do all its varied work by its own force rather than by contract. The force numbers some 125 men, engaged on concrete work of various kinds, paving and the multifarious items of work required in park improvement and maintenance. This force is under the direction of Mr. Cunliff. Dwight Davis is Park Commissioner.

Interior Fire Walls for safeguarding lives in hospitals and other public institutions, according to the plan developed by H. F. J. Porter, of New York City, have been adopted by the Department of Charities, New York City, and are to be installed in a number of the principal buildings. The department had requested from the Board of Estimate an appropriation of $200,000 to install on certain hospital buildings fire escapes and cylindrical chutes down which patients were to be slid in case of fire. Before action was taken by the Board of Estimate on this request, President McAneny had his attention called to the horizontal division fire-wall system described by Mr. Porter at the Baltimore meeting of the Society of Mechanical Engineers and in "Engineering News" of July 31, 1913. Expert investigation was made, and it was decided to install this system in place of fire escapes. The Department of Correction has also asked appropriations to construct similar walls in its institutions, which contain large numbers of inmates whose lives would be in peril in case of fire.

Flood Prevention Reservoirs in Bohemia

By Kenneth C. Grant*

Two [illegible] reservoirs for flood control are now nearly completed on the Elbe River, near its headwaters, in northern Bohemia. They are being built by the Commission for River Regulation in Bohemia. The Austrian government will pay 60% of their cost and the Bohemian government 40%.

Konigreich-Walde Reservoir

This project was begun in 1910, and in 1912 had reached the stage shown in Fig. 3, which was taken by

FIG. 1. GENERAL PLAN OF THE KONIGREICH-WALDE FLOOD-PREVENTION DAM, BOHEMIA

the writer in July, 1912. The dam is located on the Elbe River, just above Konigrinhof.

The annual rainfall over the entire drainage area above the dam averages 39.4 in. and varies between [illegible] in. and [illegible] in. The maximum 24-hr. rainfall occurred on July [illegible], 1897, and at one station, [illegible], reached 7.9 in., or 20.6% of the mean annual over the catchment area. The total rainfall at this station for this storm, July 27-31, was 11.1 in., or [illegible]% of the mean annual over the catchment area.

The maximum recorded discharge at the dam site, which occurred July [illegible], 1897, is [illegible] sec.-ft., or [illegible] sec.-ft. per sq.mi. The peak of the flood lasted for only [illegible] hr. The minimum discharge is [illegible] sec.-ft., or [illegible] sec.-ft. per square mile. The average low-water discharge is [illegible] sec.-ft., or [illegible] sec.-ft. per square mile.

The reservoir has a capacity of [illegible] cu.ft. and controls a drainage area of [illegible] sq.mi. [illegible] cu.ft., or [illegible]% of the capacity, will be kept empty for flood control. When full the reservoir extends 1.43 miles upstream from the dam and covers an area of [illegible] acres to a maximum depth of [illegible] ft.

The dam contains [illegible] cu.yd. of [illegible] masonry, and is [illegible] ft. high, [illegible] ft. wide on top, 184 ft. wide at the base and [illegible] ft. long on the crest. It is curved upstream with a radius of 656 ft. The great width of the base (91% of the height) is due to the fact that the dam is designed to take care of full uplift pressure. This was felt to be wise in view of the important towns, Konigrinhof, [illegible], etc., and the large industrial and other interests lying not far downstream. At the same time, every precaution has been taken to prevent any upward pressure due to the penetration of water into or under the dam. The upstream side has been provided with a watertight coating from the foundation up, and the interior of the dam has a complete drainage system. The maximum pressure at the toe of the dam, with full uplift pressure, is estimated to be about 12.8 tons per sq.ft. The borings and tests made of the sandstone upon which the dam is founded show that it will carry from 510 to 920 tons per sq.ft.

During construction, the river is being carried around the dam site in two tunnels, 19.7 ft. in diameter, bored through the solid rock of the hillsides. About 200 ft. above the main dam, and just below the upstream portals of the tunnels, is a low earthen diversion dam, 262 ft. long and 15 ft. high, with a masonry core wall. The tunnels empty into the river channel about 540 ft. below the main dam.

When the dam is completed, these tunnels will be closed by bulkheads, and through each bulkhead will pass three $15\frac{1}{4}$-in. pipes, provided with gates operated by spindles through a vertical shaft from a gate house above. With the reservoir full, these six pipes will discharge 3180 sec.-ft., which is the capacity of the channel below the dam. There are also two $13\frac{1}{4}$-in. pipes through the dam, provided with double gates, to supply water to the power house below the dam, where from 150 to 600 hp. will be developed by three turbines.

There are two circular spillways above the dam, one on each side of the valley, emptying into the tunnels below the bulkheads through downfall shafts. The crest of the spillway on the left bank is 853 ft. long, and is set at such an elevation that, with the reservoir full, or a quantity of 320,887,000 cu.ft., the discharge will be [illegible] sec.-ft. The spillway on the right bank (Fig. 3)

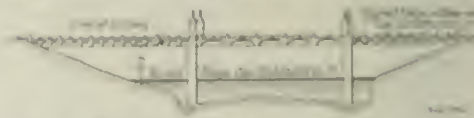

FIG. 2. ELEVATION OF KONIGREICH-WALDE DAM

is [illegible] ft. long and discharges [illegible] sec.-ft. with the reservoir full.

There is also a spillway 177 ft. long near the middle of the dam, consisting of five arched openings under the roadway across the dam, each [illegible] ft. long. The crest is [illegible] ft. below the crest of the dam proper, and [illegible] ft. below the level where the capacity is [illegible] cu.ft. The discharge over this spillway, with a depth of [illegible] ft., is [illegible] sec.-ft. With a depth of [illegible] ft., which will leave a freeboard of [illegible] ft., [illegible] sec.-ft. will discharge over this spillway. Thus if all the other outlets are out of order, the entire maximum discharge can be safely taken care of by this spillway.

Water passing over this spillway is received on a water cushion formed by a low masonry dam about [illegible] ft. below the foot of the main dam. A second water

*[illegible] Engineer [illegible], [illegible]

cushion, to receive the flow from the tunnels, is formed by a low masonry weir directly below their downstream portals. The bed of the stream is carefully paved for about 440 ft. below the dam.

Discharge Control

The discharging apparatus of the dam will be manipulated during a flood as follows: During the first part of the flood, as the reservoir is filling, the six tunnel pipes will be kept discharging at full capacity. When the reservoir is full these pipes will discharge 3180 sec.-ft., which is the capacity of the channel below the dam. If the inflow should still exceed this amount, the water would begin to flow over the spillways above described, and the maximum discharge would be taken care of as follows:

Through the six tunnel pipes	3,180 sec.-ft.
Over the left circular spillway	2,470 sec.-ft.
Over the right circular spillway	3,880 sec.-ft.
Over the dam spillway	2,120 sec.-ft.
Total	11,650 sec.-ft.

If the tunnel pipes were out of commission, the total maximum discharge could pass over the three spillways with an increased depth of only 0.75 ft., leaving a freeboard of 7.13 ft. If the two downfall shafts were also out of commission, as noted above, the dam spillway could carry the maximum discharge and still leave a freeboard of 4.7 ft. All the provisions for discharging more than 3180 sec.-ft. are considered by the designers of the dam to provide a very large factor of safety, because records show that the peaks of the floods last but a short time and will always have passed before the reservoir is full.

The total cost of the reservoir, including land, damages, etc., will be $965,000, or $3000 per mill. cu.ft. of storage.

Krausebauden Reservoir

The construction of this project was begun in 1910 and is now practically completed. The dam is located near the headwaters of the Elbe River, a short distance below the town of Spindelmühle, and 21.4 mi. above the Königreich-Walde dam.

The annual rainfall over the entire drainage area above the dam averages 47.2 in., and varies between 35.4 in. and 55 in. The maximum 24-hr. rainfall and the maximum rainstorm are as noted above for Friedrichsthal, which is near the dam site.

The maximum recorded discharge at the dam site, which occurred in July, 1897, is 7060 sec.-ft., or 315 sec.-ft. per sq.mi. The minimum discharge is 10.6 sec.-ft., or 0.472 sec.-ft. per sq.mi. The minimum low-water flow of long duration lasted for 100 days, and averaged 35.3 sec.-ft., or 1.58 sec.-ft. per square mile.

The reservoir controls a drainage area of 22.4 sq.mi. and has a capacity of 119,191,400 cu.ft., 105,900,000 cu. ft., or 88.5% of which will be kept empty for flood storage. When full, the reservoir is 1.12 miles long and covers an area of 71.7 acres to a maximum depth of 107 feet.

The dam contains 65,450 cu.yd. of broken-stone masonry and is 136 ft. high, 16.4 ft. wide on top and 118.2 ft. (87% of the height) wide on the base. It is arched upstream and has a crest length of 492 ft. The dam is designed for full uplift pressure. The greatest pressure

Fig. 3. Looking Upstream at the Site of the Königreich-Walde Dam during Construction

at the downstream toe of the dam with the reservoir full is 12.4 tons per sq.ft. With the reservoir empty, the pressure at the toe of the dam is 1.28 tons per sq.ft., and at the heel is 8.25 tons per sq.ft. The dam is founded on a hard gneiss, rich in quartz, which was reached at a

Fig. 4. Konigsreich-Walde Dam. Spillway above Dam on Right Side of Valley

depth of from 13 to 16 ft. in the bed of the stream and of about 3 to 4 ft. on the sides of the valley.

The foundation for the dam was prepared, after excavation, by filling all cracks in the rock surface with cement mortar. Twenty-three small springs which had been encountered were enclosed in vitrified clay pipe, from 6 to 8 in. in diameter, so that they could be safely conducted out of the dam by the drainage system. The whole bed of the stream was then leveled up with concrete of a 1:2:4 mixture in a terraced form to give a uniform footing for the dam.

To prevent the entrance of water into the dam it is provided with a reinforced-concrete facing on the upstream side. The Hennebique system was used in the construction of this facing. In addition, the upstream face has been given two waterproof coatings. The interior of the dam is provided with a complete drainage system.

The water was carried around the dam site during construction in a tunnel 13 ft. in diameter and 475 ft. long, bored through the solid rock of the hillside around the left end of the dam. The flow was diverted into this tunnel by a concrete dam 21.6 ft. high, about 210 ft. upstream from the main dam. This diversion dam is arched upstream and is faced with masonry about 20 in. thick on the downstream side.

The diversion tunnel is now closed by a bulkhead through which pass five [illegible]-in. pipes with gates operated by spindles through a vertical shaft from a gate house above. With the water 31.2 ft. below the spillway, at which level the flood-storage capacity of the reservoir is empty, these five pipes will discharge 2470 sec.-ft., which is the capacity of the channel below the dam. With the reservoir full these pipes will discharge [illegible] sec.-ft.

On the left side of the valley above the dam there is a circular spillway 197 ft. long, with its crest 9.52 ft. below the crest of the dam. This spillway discharges through a downfall shaft 16.4 ft. in diameter into the tunnel below the bulkhead. With a depth of 1.92 ft. on the crest, the discharge over this spillway is 1235 sec.-ft. With a depth of 3.61 ft., the discharge is 3530 sec.-ft.

There is also a spillway 131.2 ft. long over the main dam at the right end, consisting of four arches, each 32.8 ft. wide in the clear. The crest of this spillway is at the same level as that of the circular spillway above the dam, i.e. 9.52 ft. below the crest of the dam. With a depth of 1.92 ft. on the crest, this spillway will discharge 1235 sec.-ft.; with a depth of 3.61 ft., 3530 sec.-ft.; and with a depth of 5.58 ft., 7060 sec.-ft. The discharge from this spillway is conducted between training walls over a paved cascade on the rocky side of the valley to the paved stream-bed below the dam, where it falls into a water cushion, later described.

There are also two $13\frac{3}{4}$-in. pipes through the dam, with gates above and below the dam. These furnish water to a small power house below the dam where 120 to 150 hp. will be developed. They are not reckoned as a part of the equipment for flood-control manipulation.

Discharge Control

The manipulation of the reservoir during a flood takes place in this manner. During the early part of the flood, the five tunnel pipes are kept discharging at the rate of 2470 sec.-ft., the capacity of the channel below the dam. As soon as the inflow exceeds this amount, and the flood-storage capacity begins to fill, the gates are gradually

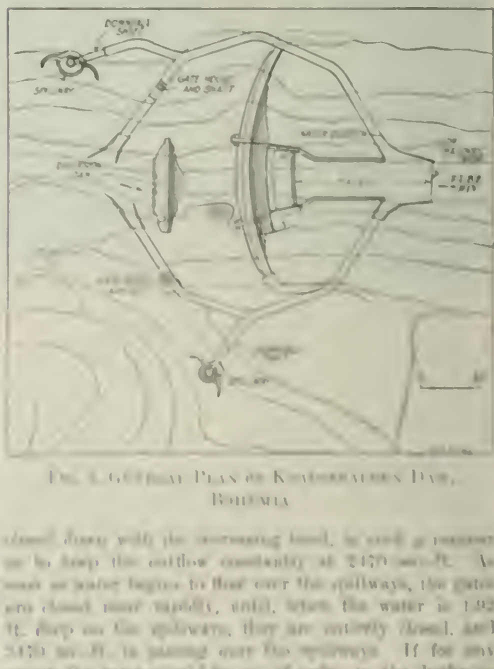

Fig. 5. General Plan of Konigsreichwalde Dam, Bohemia

closed down with the increasing head, in such a manner as to keep the outflow constantly at 2470 sec.-ft. As soon as water begins to flow over the spillways, the gates are closed more rapidly, until, when the water is 1.92 ft. deep on the spillways, they are entirely closed, and 2470 sec.-ft. is passing over the spillways. If for any reason the gates should be out of order, or the discharge pipes blocked, the maximum recorded discharge, 7060 sec.-ft., can be accommodated by the two spillways with a depth of 3.61 ft. on their crests. Further, if the circular spillway or downfall shaft or tunnel should for

any reason be out of commission, the entire 7060 sec.-ft. could be taken care of over the main spillway alone, with a depth of 5.58 ft., and still leave a freeboard of 3.94 ft. below the crest of the dam proper.

About 250 ft. downstream from the toe of the dam, a concrete weir, 4.3 ft. high, has been built to provide a

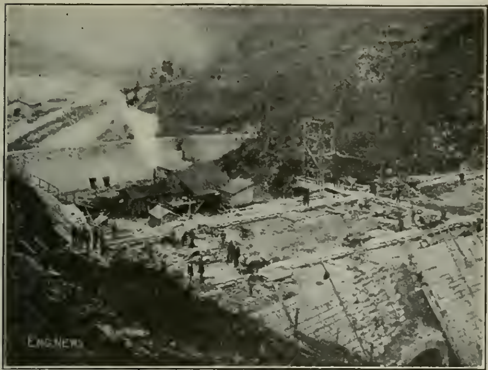

Fig. 6. Krausebauden Dam in Course of Construction (Looking Upstream, Showing Diversion Dam.)

water cushion to receive the discharge from the tunnel and the cascades leading from the dam spillway. The upstream training wall of the cascades is extended across the stream bed about 130 ft. above this weir, and joins the upstream side of the tunnel portal. With 2470 sec.-ft. discharging from the reservoir, a water cushion about 8 ft. deep is provided in the space between the training wall and the weir. This space and the streambed for about 25 ft. below the weir is carefully paved with masonry 3 ft. thick.

The Work of the River-Regulation Commission

The Commission for River Regulation in Bohemia has been in existence since 1903. Since that time it has been carrying out a well defined plan of river improvement, including reforestation, improvement of mountain torrents, regulation of stream channels and construction of flood-prevention reservoirs.

The Commission has investigated 103 sites for storage reservoirs on the Elbe Basin in Bohemia. These reservoirs would have a total capacity of about 20,000,000,000 cu.ft. and would control a drainage area of abut 5840 sq.mi., or about 30% of the Bohemian Elbe Basin, which has an area of about 19,800 square miles.

It is calculated that this system of reservoirs would have stored one-quarter the total flood run-off of the Bohemian Elbe in the flood of 1890. The maximum discharge of 158,800 sec.-ft. would have been reduced by 56,500 sec.-ft., or to 102,300 sec.-ft., a reduction of 35.6 %. The maximum stage of 26.2 ft. would have been reduced to 19.7 ft., a reduction of 6.5 ft. A stage of 19.7 ft. is not usual, and does little damage. Ordinary floods of 19.7 ft. would be reduced to 11.5 feet.

Of these 103 projects, 23 have been decided upon, and six have been built or are under construction, including the two above described. These 23 projects will have a total capacity of about 5,000,000,000 cu.ft., and will control a total drainage area of 1730 sq.mi. Comparing the greater rainfall over their catchment areas with the average over the entire basin, their controlled area is equal to 2420 sq.mi., or to 12.2% of the entire Bohemian Elbe Basin.

It is estimated that these 23 reservoirs will reduce maximum floods on the main Elbe, above the German border, by about 1.3 ft. The reduction further upstream will, of course, be considerably greater.

The total cost of the 23 projects is $12,100,000. The cost of the six now built or under construction is $2,503,000; leaving $9,597,000 to be expended for the other 17, which will be built in the next few years, as money is made available by the government.

About 20% of the total capacity will be used to retain flood water for the increase of low-water flow. The other 80% will be kept empty for flood control.

The studies of the Commission show that a total storage capacity of about one-quarter the total capacity of the 103 projects above mentioned would, if used for that purpose, raise the low-water stage of the lower Bohemian Elbe to navigable stage for a month.

The South American Field

By Cyrus T. Brady, Jr.*

SYNOPSIS—Many manufacturers and engineers in the United States are looking for opportunities to develop business in South America. The difficulties which must be met and overcome in order to do this are set forth by Mr. Brady from knowledge based on a personal experience of some years on engineering construction in various South American countries. He shows that while labor is cheap, materials are dear and the engineer from the United States must radically revise his standards of design and in many respects learn his business over again if he would succeed in South America.

There exists a widespread belief that South America is a continent of vast wealth in a sadly undeveloped condition, which awaits only the magic touch of the American engineer, or man of commerce, to pour forth streams of this wealth for their enrichment. This idea is very erroneous, at least in regard to the Argentine, Uruguay and Brazil, with the first of which this article is mainly concerned. The general conclusions deduced will, however, apply directly to the whole East Coast and in a less degree to Chile; or, in other words, to the great majority of the area and population of the continent. The information given will supplement the writer's letters published in Engineering News of Apr. 30 and Sept. 3 of this year.

As was stated in his last letter, the cost of living is very high in Buenos Aires. James Bryce, in his book on South America, has stated that he found it higher there than in

*615 Lake St., Elmira, N. Y.

St. Petersburg itself (or to be in fashion "Petrograd")—long known as the world's most expensive city. The cost is only slightly less in Montevideo and Rio. In some of the other cities of the three countries, the cost of food and lodging is lower, but clothing, amusements, books and other general expenses are on a par in all. The writer's personal experience extends to Salta, Tucuman, Santa Fe, Corrientes and Rosario, as well as Buenos Aires in the Argentine, to Montevideo in Uruguay, to Santos, Sao Paolo, Bahia and Rio de Janeiro in Brazil, and he has had many opportunities of conversing with men familiar with other cities.

Of course, in parts remote from the great cities, lodging and simple articles of food are cheaper; but all other expenses are greatly increased so that on the whole the cost of living with even a very modest amount of comfort is about a third higher than in the United States. The cost of living is but one factor which must be reckoned with. Accompanied by high custom duties, high rents, high wages of employees and the expenses attendant upon the giving of long-term credits, the cost of doing business is so high that only companies with large capital and with the most intelligent administrative ability are able to bear the burden of the development of their business. South America is slow to adopt new articles of commerce, and competition has been so keen that only the very best, considering both cost and quality, have established themselves. Yet, once established, it is difficult to dislodge them from favor. Many persons are apt to forget that there are already several American importing firms operating in South America in a more or less healthy economic condition and that they are much more likely to profit by our present lack of competition from Germany and Belgium than are newer organizations or representatives of manufacturers.

The average American engineer probably is not aware that some of the ablest European engineers have devoted much of their time to our sister continent and that many of their works will bear the closest scrutiny. To mention only one name: the Argentine Province of Mendoza years ago employed the famous Italian engineer, Cippoletti, to design a large number of irrigation works. Some of these works have since failed but the works which replaced them have profited by the dearly acquired experience. In this connection it should be noted that there are many irrigation systems built or building in Argentina, which, while not comparing in size with some of our gigantic Reclamation Service projects, will compare very favorably for detail.

The writer was employed by the Argentine Government on the design of the headworks for an irrigation system in the Province of Salta and was amazed at the thoroughness [illegible] in the well made topographical surveys of the irrigable lands, the general survey of the entire drainage area, the careful investigation and solution of the complicated problem of the [illegible] of the existing irrigation water rights and other details, legal or technical. Some of the existing irrigation systems have been in use for hundreds of years and [illegible].

In all the [illegible] cities the street railways are of the most improved types. Buenos Aires has a two-track subway line [illegible] miles long, provided with a station where electric trains of one of the railroads carrying much [illegible] traffic [illegible] passengers with the subway trains. Directly underneath the subway runs a single-track tunnel by which the freight trains of the same railroad reach the port. The construction of this tunnel is being carried out in the most satisfactory manner by C. H. Walker & Co., the great English contractors, while the engineers of the subway were German and the work was done by Philipp Holzmann & Co., also of Germany.

Of the ports it is unnecessary to speak at length as they have recently been described in ENGINEERING NEWS.* The port equipment is in general much superior to that of New York. Santos, Rio and Montevideo all have, in service or building, ports of the same excellence as those of the Argentine. Although much lighterage is done, especially in transporting goods from the steamers directly to factories or warehouses situated on water fronts, the great bulk of the freight is transferred by the most modern cargo-handling machinery. The ships tie up to massive masonry quay walls which are lined with extensive bonded warehouses, grain elevators, cattle pens and the like.

In the Argentine a type of river quay wharf which has given much satisfaction has been developed in timber or reinforced concrete. The accompanying sketch (Fig. 1) is merely diagrammatic but indicates the new type of construction in the Riachuelo of Buenos Aires, which is a [illegible] river with these quays facing the banks. The sketch also shows a part of one of the three large transporter bridges across this stream. The caisson was made in place as it was being lowered, advantage having been taken of the [illegible] to form a working stage. The piles were then driven and the caissons filled with a lean concrete. The work was designed and constructed by Messrs. Wayss & Freytag.

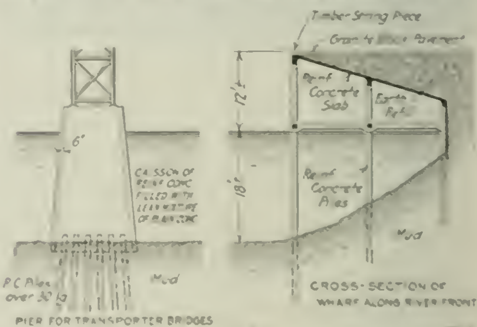

FIG. 1

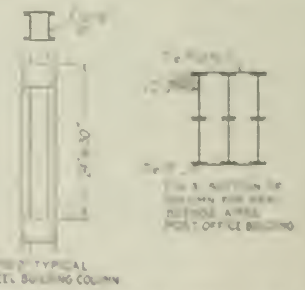

FIG. 2. TYPICAL STEEL BUILDING COLUMN

In reinforced-concrete building construction several bold projects have been accomplished, largely due to the initiative of the German contractors just mentioned and Philipp Holzmann & Co. In Buenos Aires, the latter firm has built an [illegible] building the general [illegible]

*[illegible] "Engineering News" [illegible]

of which rises to sixteen stories. There are three or four concrete buildings in service, eight to ten stories high.

Steel building construction is carried out by European companies and by the export branch of the United States Steel Corporation. In addition there are two large and several small structural shops in Buenos Aires where fairly good work is turned out (from German or Belgian material), at a slightly higher cost than for imported steelwork. The writer remembers that on one occasion when 250 tons of grillage beams, cut to length and part of them punched for separators, were required, both companies agreed to deliver the work within 48 hr. This was, of course, sooner than the material was needed, as the bidders may have known, but the job was never held up an instant waiting for delivery; whereas the shipments arriving irregularly from foreign countries often cause delays on the work.

These delays and similar unavoidable annoyances are of constant occurrence in the export field and the greatest energy and tact are necessary in dealing with them. Americans as a race are well endowed with the former quality but are often criticized for their comparative lack of the latter, and this is much to be regretted as it is the quality above all others necessary in dealing with the Latin-American temperament. The importance of tact, or better, of understanding of and consideration for the customer, is felt not only in personal relations but in all forms of commercial activity.

To present this point more clearly a specific example will aid. It is a matter of almost common knowledge that the invoices, packing lists and so on, which accompany export shipments, are prepared by many American manufacturers in the most slovenly manner. Sometimes they are quite unintelligible to the customs broker in South America whose knowledge of American technical terms is always weak. An item like

1 Cr. Mark 312. Containing one Type A Former with No. 3 reverse bar hoop spider

means absolutely nothing to anyone except to the manufacturer who supplied it. This should be billed on the manifest as "Repair part for barrel-making machine" or something of the sort. In one instance, an experienced customs broker called upon the writer to explain whether the item

40,000 ft. 2 in. ammonia piping, with screwed fittings

should be declared as wrought iron or as cast iron, this classification being compulsory in the formal declaration to the customs officers. Doubtless to anyone familiar with the pipe trade the answer is self-evident, but it is not so to a customs broker. Another very embarrassing experience of no infrequent happening is that a box, which has been declared through a misunderstanding of the invoice to contain iron screws, may be found full of copper bolts, or other articles equally difficult of explanation to the customs officer.

The same principles apply to technical matters. Thus in bidding on a steel bridge it is not sufficient to inclose a blueprint stress sheet in a letter offering to furnish the fabricated steel only, for a certain lump sum, c.i.f. South American engineers are not accustomed to receive designs or to prepare them in this manner, nor do they care to let the contract for steelwork to one contractor, the erection to another, masonry and foundations to a third, surfacing to a fourth, etc. What is desired is a price for the bridge complete and ready to be opened to the public, thus including every cost connected with the work. Even were they disposed to contract for the steel as a separate item, the stress sheet with its usual scale in inches to the foot and its meager detail would fail to satisfy them.

Engineers in Europe and South America know very little of the practically standard details which any American structural shop turns out, as a rule, so satisfactorily. "American Railway Engineering Association Specifications" naturally means next to nothing to them. When they prepare designs of their own, large scale general drawings are furnished and amplified by details of particular points. A thesis invariably accompanies the drawings. This will contain a general description of the whole work and will discuss in detail the loads and stresses to be used. Methods of computation and design will be described and what amounts to an elaborate specification for materials, workmanship and construction will be given, followed by carefully estimated weights and other quantities. All the drawings and the thesis are usually bound together in a portfolio.

The cost of preparing designs in this style is, of course, considerable; but if competition of other enterprising contractors is to be met, it must be borne without reluctance. In passing it might be mentioned that, in one way, the theses often seem rather child-like. They always assume, tacitly, that the work being described is the first of its type ever conceived, and many self-evident details and even the commonest engineering formulas are developed at great length.

In competitive bidding with European firms a point of some difficulty concerning the columns often arises. In the first place, the sections used are wofully deficient from our point of view. The sketch (Fig. 2) shows the type usually employed in buildings. Fig. 3 is one proposed for the new post office of Buenos Aires, and the engineer of the American company which furnished the steel had great trouble in securing approval for his substituted design which was more in conformity with our standards. A second difficulty is the constant European use of Euler's formula. This formula does not reduce the stress below the allowable value in pure compression, for bridge or even building members of ordinary length. In Europe itself the building ordinances specify loads and stresses which are safe when used in connection with it. In South America where the stresses are commonly taken much higher, it allows loads which are too great; and it is useless to object as European practice is instantly referred to as final; the differences in the allowed stresses in pure compression are dismissed as being of little importance.

It should be evident from the examples cited that in placing any new engineering materials, or types of construction, or machinery, or other manufactured commodity on the South American market, much study must be given to types already in use, which are in any way similar to the one proposed, and to the desires and habits of the customer. What he wants and how he wants it should be the aim of every investigation. Only by following this method will success attend the effort to win his trade.

We have discussed the methods to be adopted more from the viewpoint of the American exporter than from that of the engineer or capitalist interested in engineering works. One of the topics of most interest to these two classes is,

of course, the labor situation. It has been said epigrammatically that in the Argentine the labor of the country is Italian, the shopkeepers Spanish, the commerce English and German, the culture French, and that the only occupation of the natives is selling land to foreigners or borrowing money on what remains in their possession. Were this statement perfectly true, it would be a simple matter for engineering companies to carry on their work, for there seems no part of the earth where Italian labor is not familiar and appreciated.

Unfortunately, the situation is much more complicated since the laborers in fact come from all the nations, from Scandinavia to Asia Minor. A personal experience will indicate the complexity of the situations which must be met daily by an engineer on construction work. On a certain reinforced-concrete, steel-frame building, the foundation contractor was a Frenchman and his foreman an Italian; the concrete work was done by a German firm with German and Italian foremen; the structural steel was supplied by an English company and erected by a superintendent hailing from Gibralter, assisted by Spanish foremen; the electrical equipment was installed by an American concern under that great rarity, an Argentine foreman, and this variety of nationality extended to the other subcontractors.

Constant friction arose between the Germans and the Spaniards, and most of the writer's time was taken in smoothing out the differences and in trying to induce the disputants to apply the energy used in their quarrels to the furtherance of the job. This is a task which permits a man to make use of all the tact and knowledge of human nature which he chances to possess; and, in so far as he is successful, returns to him the greatest reward the engineering profession offers—the keen pleasure of the management of men.

It will be profitable to enlarge on the labor question and the following approximate list of the wages prevailing in Buenos Aires may be useful. All are given in American cents per hour. The common day's work on construction is 10 hours, although stevedores and some other trades work but eight.

[illegible]

In rural districts, where labor is largely agricultural, the day's wage is [illegible] $1.25 with food, or $1.75 without. In undeveloped districts, such as the province of La Rioja, the figures shrink to about [illegible] to $1.10.

[illegible]

tractor, without profit, of ordinary reinforced-concrete building work in Buenos Aires. The table is an average of several buildings and is rather low than high.

Cement, 1.5 bbl. @ [illegible]	$[illegible]
Gravel, 0.9 cu.yd. @ 3.50	3.15
Sand, 0.45 cu.yd. @ 1.[illegible]	0.7[illegible]
Labor mixing and placing	1.80
Superintendence	0.4[illegible]
Forms, labor and material	3.[illegible]
Reinforcement in place, [illegible] lb. @ [illegible]	3.[illegible]
Power, light, water [illegible]	1.[illegible]
Plant, development and depreciation [illegible]	1.[illegible]
Interest, insurance, clerical expenses	1.[illegible]
Cost, without profit, per cubic yard	$21.70

It will be noticed that the labor costs are much lower than those of materials, and this will explain why many of the devices and methods used in other countries to dispense with extra labor have not come into general use here. The lessons drawn from the two tables may be extended to other fields of engineering work. Hand labor and horses are so cheap that, regardless of their rather low efficiency, machinery must be of a very exceptional usefulness to supplant them.

Even in the field of railroad construction, hand labor and horse-drawn vehicles or equipment are the rule. The vast plains of Argentine are broken by so few hills or elevations that large cuts and fills are far apart and steam shovels would soon "eat off their heads" in general charges while moving long distances to excavate but small yardages in any one spot.

On the other hand an enterprising American contracting engineer has had much more work offered him in Santa Fé province than he is able to carry out with his American ditch-digging machine. There are enormous tracts of semi-swamp lands along the Rivers Plate and Parana, which only require drainage to be most productive, and here this type of machine has proved more economical than hand labor.

One or two makes of concrete mixers are already in use, and their sale and that of other good types can be extended. Concrete distributing machinery could also be introduced with profit to replace the present method of heavy $\frac{1}{2}$-yd. skips running on 24 or 36-in. gage track. Large automobile trucks are rapidly increasing in number in cities, for there the cost of maintenance of horses is greater. A few road rollers are to be seen, naturally only in the cities, as the country roads are almost entirely unsurfaced. Scrapers and drags might be introduced to care for these. Small pumping plants could be installed in many places where the omnipresent windmill does not render sufficient supply. Taking advantage of the present cessation of German and British competition, our trade in electrical supplies and in light, power and street-railway plants and equipment can be increased. Many inquiries for structural steel and cement have already been received. We have developed a healthy commerce in steam-railway equipment, and it can be increased. The [illegible]

[illegible]

omy of labor, rather than of material, and we have seen that practically the reverse is true in Latin-America. Still it is patent that where engineering competition is so keen, any saving in labor would be of value. A few months since, shortly after the writer's return home, he was privileged to inspect closely a concrete warehouse being built by the Turner Construction Co. His instant remark was, "If you chaps were to go to South America, you could put every other contractor there out of business." Whether such a prophecy could be realized would depend very largely on the successful solution of many of the administrative matters mentioned in this discussion and on others, such as ability to play politics, or to keep out of them, when necessary.

The North American product which will prove of greatest value in South America is not some special type of machinery, but rather the type of man who can understand the character of its people.

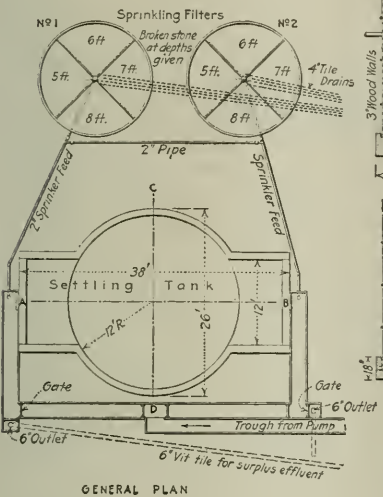

Fig. 1

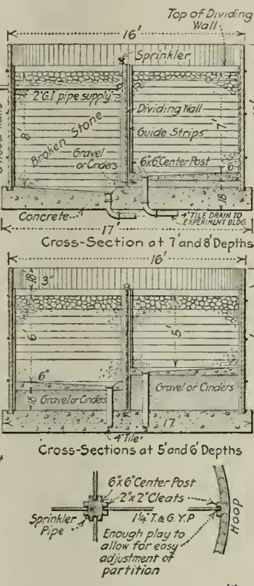

Fig. 2

EXPERIMENTAL SEWAGE-TREATMENT PLANT, INDIANAPOLIS, IND.

Experimental Sewage Treatment Plant at Indianapolis

The city of Indianapolis, Ind., has for some time been considering the question of sewage treatment in order to avoid the present pollution of White River, and during 1913 an experimental plant was built. This consists of an Imhoff settling tank, two sprinkling filters, an electrolytic tank, and a laboratory building. This plant is located near a 6-ft. sewer, from which the sewage is taken as required, and to which the effluent is returned. The electrolytic process was found unsuitable to the character of the effluent and has been abandoned.

The city, with a population of 250,000, has an average total daily discharge of 11,000,000 gal. of sewage and trade wastes (into White River), and the experimental plant has a capacity for treating 240,000 gal. daily. It was put in service in March and will be operated for about 12 months, after which the question of a permanent plant will be considered. The fact that the sewage contains a rather high percentage of trade wastes is a special factor in determining the most satisfactory treatment.

A plan of the plant is shown in Fig. 1. The 6-ft. circular sewer is divided into two rectangular channels 3 ft. wide. One of these has a double set of inclined bar screens to remove the solids, and from this the sewage is pumped. This channel can be shut off by a gate, and the other channel serves as a bypass. The sewage is pumped to a wood trough fitted with gates, and is delivered first to a settling tank of the Imhoff type, rectangular on top (36x24 ft.) and having a circular sludge chamber 24 ft. diameter. The total depth is about 33 ft. An 8-in. pipe extends to the bottom of the chamber. The tank is of reinforced concrete, but considerable trouble was experienced with leaks, and extra time and work was necessary to get it watertight. The upper portion is fitted with steel baffle plates.

The effluent from the settling tank flows by gravity through 2-in. galvanized pipes to the sprinkling filters, 8 ft. diameter, shown in detail in Fig. 2. They are of wood construction, each divided into four compartments filled with broken limestone of 1½-in. size in one filler and 2-in. in the other. The depth of stone varies from 5 ft. to 8 ft., to determine the effects of different depths. The bottom is of concrete with gravel fill and concrete floor for the shallower compartments. The two tanks are identical in construction and are used alternately. The 2-in. supply pipe ends in a sprinkler head, and each compartment has a 4-in. vitrified tile drain leading the effluent to a sampling tank in the laboratory building, which is built over the sewer.

A typical analysis of the sewage is as follows: organic nitrogen, 21.4 parts per million; free ammonia, 6.6; nitrite-nitrate, 1.0; oxygen, 34.0; chlorine, 122.0; suspended matter, 200.

The plant was designed and built under the direction of H. W. Klausmann, then City Engineer, but has been modified by B. J. T. Jeup, the present City Engineer. When put in operation it was inspected by Geo. W. Fuller, as consulting engineer for the city, and he will make the necessary study of the results in relation to the design of the permanent plant. The operation is under the charge of H. C. Underwood, City Chemist.

A Wireless Telephone System is being installed by the Union Pacific R.R. for communication with its overland trains. There will be stations at Grand Island and North Platte, Neb., Cheyenne and Green River, Wyo., and Ogden, Utah. High towers and heavy sending equipment (5- and 10-kw.) will be used to overcome communication difficulties in the Rocky Mountains.

The Relation of Geology to Railway-Tunnel Location*

By Edwin C. Eckel†

Most railway tunnels are so located as to pass through a barrier range at some relatively low point. The railroad was headed for a gap or pass through the range in order to secure as low a crossing point as possible, and the tunnel represents an effort to make a little farther reduction in the elevation of the crossing point.

The fact that a gap or pass exists at a certain point in a mountain range is not a matter of accident; there is always a cause for its location at that particular point.

Fig. 1. Gap Caused by Erosion of Softer Rock

Fig. 2. Gap Caused by Erosion of Weak Crest of Arch or Anticlinal Fold

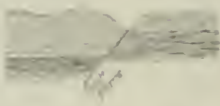

Fig. 3. Gap Caused by Erosion along Weakened Fault Plane

Fig. 4. Gap Due to Overlapping Folds

In most cases, it is possible to say, after study of the case in the field, that the pass owes its location to some peculiarity in the structure or composition of the rocks at that point.

Other things being equal, depressions along a mountain ridge are likely to occur where soft or soluble rocks reach the ground surface. If the rocks of the range are so placed that a depression of this kind extends at right angles to the range, it may in time be extended entirely across it, giving rise to a gap. Fig. 1 illustrates a hypothetical case of this kind, where a series of limestones, inclosed by harder rocks, have been worn down below the general crest level. On a small scale, gaps owing their origin to this cause are fairly common.

A second cause is erosion of the crest of an arch or anticline. Fracturing is common at this point during the folding of the rocks, and the weakness thus induced may at a later date give rise to deep erosion along the weakened zone, and the ultimate formation of a gap across a ridge. This is illustrated in Fig. 2, showing a condition which could be readily duplicated in many parts of the South.

Faulting on a large scale also causes zones of weakness and easy erosion, and gaps may arise from this cause as shown in Fig. 3. In many cases, where a gap or pass is located along a fault zone, we have to deal not only with such weakness as may have been the direct result of faulting, but with the fact that the fault may have brought into contact at the surface two sets of beds differing widely in hardness and resistance to weathering. In such cases, the gap is due to the indirect effects of the fault, rather than to the direct structural weakness.

Another very common type of gap, particularly in certain portions of the southern Appalachian region, is that caused by the arrangement of the rock folds and, consequently, of the mountain masses. This can be seen best along the line of the Chesapeake & Ohio R.R. in the section near the Virginia-West Virginia state boundary, where examples are encountered at frequent intervals. The rocks of this area are arranged in steep folds, and in most cases the mountain ridges represent actual arches or anticlines in the underlying rocks. Cross folding at intervals causes an echelon arrangement of the ridges, and the roads and streams follow through around the ends of these ridges at relatively low crossings. Fig. 4 is an attempt to suggest the main features of this sort of topography.

If the entire ridge which has to be tunneled were composed of one kind of rock, if the structure of this rock were everywhere uniform, and if no faults or other dislocations existed, it would, of course, make little difference where the tunnel was driven. Such homogeneous rock-masses are frequently found in textbooks, but they are really quite rare in the outside world. Usually the engineer will find, on examining the ridge which faces him, that it is made up of several distinct kinds of rock, that these kinds of rock differ in hardness and other physical characters, and that different portions of the ridge probably show differences in the formation of the rocks. All of these facts will have some bearing on the cost of driving and operating the proposed tunnel; and it will be well to get some idea in advance as to how the ground conditions can be made to fit in best with the other requirements of the line. If a relatively slight shift in alignment is going to give cheaper work, either in construction or operating, without bringing in any serious new difficulties, it will certainly pay to make the change.

Shale—Cutting through shale usually means fast driving and cheap extraction, for the material breaks so readily that the quantity extracted per man or per pound of powder is commonly far higher than in any other rock. But when this is said, all the advantages have been mentioned. The final completion of the tunnel may be dangerous and expensive, and the cost of maintenance may turn out very high unless it is completely lined at once. In some cases, timbering must follow up close behind the heading, in order to prevent falling fragments and to retain the roof lines. Shale is ordinarily full of closely set joint planes. On a freshly exposed surface, these may not show markedly, but exposure to the air induces "slaking," the joints open, and the shale breaks into fragments. Further than this, water is apt to be carried in quantity along some of the more strongly marked joint planes.

Slate—The material reported as slate in the progress of the work may be a real roofing slate, but it is more apt to be a dense shale, breaking out in tabular masses instead of irregular fragments. In either case the driving is easy if the bedding or cleavage are at such an attitude that advantage can be taken of them, but easily becomes difficult and expensive. There is less frequency of falls of roof during working than in dealing with other shales, but on the other hand the use of the

*Abstract from a forthcoming book on "Geology as Applied to Engineering Work."

†Geologist, [illegible], Washington, D. C.

falling masses makes the matter more serious when it does happen. If the bedding is vertical or nearly so, lining will usually be unnecessary; if the bedding is horizontal, falls may be expected to occur at intervals. The importance of the tunnel will then have to determine whether all of these should be guarded against from the outset.

Sandstone—Sandstones vary widely in physical properties, from thin-bedded fragile materials that can be readily broken with a pick up to dense vitreous quartzites that will wreck all the tool steel on the job.

Quartzites are sandstones in which the original quartz grains have been cemented together by infiltrating silica. They are dense, resistant to physical and chemical changes, difficult and expensive to excavate. Fortunately, they occur principally in regions of extreme metamorphism, and are therefore common only in certain mountainous portions near the eastern and western coasts, and in the Lake Superior region. In steeply folded regions, the quartzites may be barely jointed. In this case their excavation is easier, but at the same time the joint planes give access to water.

Throughout most of the central and eastern United States, the sandstones found are reasonably dense, varying from stones like the Berea stone up to the much denser and tougher bluestones or flagstones. They give fairly cheap driving, especially where the bedding is in a favorable attitude, and make excellent roofs and sides. Taken as a group, sandstones of this intermediate type probably furnish the cheapest tunnel work, when construction and maintenance both are considered.

West of the 95th meridian, most of the sandstones encountered in the plains region and along the immediate Pacific coast are fragile, thin-bedded materials, readily excavated and yet commonly strong enough to hold position after the cut is driven.

Gneiss—The banded metamorphic rocks, such as gneiss, schist, etc., will differ greatly in difficulty of treatment, the variations being due not so much to differences in mineral or chemical composition, as to the attitude of their banding or apparent bedding planes, the thickness of the plates or beds into which they are separated, and the presence and relative importance of joints. A gneiss lying horizontally or nearly so, and without frequent joints or thin banding, is perhaps more expensive to handle than any granite. On the other hand, a gneiss or schist whose banding is at right angles to the course of the heading will commonly break almost as readily as flagstone. In any case, except where joints are very numerous and open, the roof and sides will be secure. Water softening with lime and then allowing the turbidity to settle out, along with the precipitated carbonates. Turbid water has never been successfully disinfected with hypochlorite, because the bacteria imbedded in the suspended matter are not destroyed.

(7) The sterilizing action persists indefinitely. In a paper on water disinfection by chemical methods, Samuel Rideal states the advantages of using chemicals that persist in their disinfecting action, in the following words: may enter either along the apparent bedding planes, or along joint planes; but ordinarily the quantity will not be serious.

Granite—For convenience, all of the massive igneous rocks may be included here under this heading, and as a matter of fact most of them will be true granites or closely allied. Under ordinary circumstances, rock of this type will afford very expensive excavation, but good sound roofs and sides, and practically no water troubles. One point is worth bearing in mind. Granites do not have any bedding planes, and ordinarily show little banding or foliation. But even the densest and most massive looking granite will break with considerably greater ease in one direction than in another. This direction can only be found by experiment in each case, but it is worth going to this trouble early in the work in order to secure extra efficiency in drilling and blasting operations later.

Limestone—Limestones differ from all the roofs which have heretofore been mentioned, in a very striking and important way. The other rocks, from shales to granites, weather chiefly or entirely from an exposed surface, so that if the rocks exposed on the ground above the tunnel alignment seem fresh, there need be little fear of striking decayed rock in the headings. But limestone acts differently. It is very soluble, and water penetrating along joint planes or through the mass of the rock itself will gradually work out large channels or cavities to a great depth. These may remain open, or be partly filled up by "clay seams."

Limestone is an easily handled rock, and a sound thick-bedded limestone will make for cheap driving and good roofs and sides. But in driving a limestone tunnel there is always the chance that the next blast will play havoc with all calculations by opening up a clay seam, a cave, or a water channel. The difficulty is not so much the increased expense, as the fact that the interruptions are unexpected and so hard to guard against in advance.

Owing to differences in composition, texture, bedding, position and climate, limestones show wide differences in solubility and cavity formation. Other things being equal, caves and large water channels are most likely to occur in a limestone lying horizontally or nearly so. On the other hand, steeply dipping limestones will frequently show clay seams extending from the surface downward for 50 ft. or more.

These facts may be used for guidance. If the ridge consists partly or entirely of flat-lying limestone beds, the presence of known caves in the same general region, or the existence of exceptionally large springs breaking out along the flanks of the ridge, should serve as a warning. On the other hand, if the beds dip at angles of 35° or more, attention should be paid to their appearance along a line across the ridge over the tunnel alignment. The occurrence of bands of red or deep yellow clay, apparently interbedded with sound limestone, will in that case suggest that these seams may go deep enough to be encountered in the tunnel work.

Rock Folds—It is but rarely that a tunnel passes through rock beds lying flat or nearly so, because low points in ridges do not usually occur in areas of horizontal and undisturbed rocks. Normally, the rocks will be dipping at fairly high angles, which may indeed approach the vertical. Normally, also, the strike or trend of the rocks will be more nearly at right angles to the course of the tunnel than parallel to it. These conditions arise from the general modes of origin of mountain ranges and passes

Whatever the angle of dip, the rocks will break most readily from a bedding plane, slips and falls will commonly originate on such planes, and the chief water flows may be expected along them. The presence of numerous

or very open joints may, however, operate to modify these conditions. So far as work is concerned, if the rock beds dip parallel to the axis of the range, the blasting will be less effective, and the water troubles greatest; if the beds on the contrary dip into the mountain, the excavating work will be cheapest, though perhaps more dangerous, while the chance of heavy water flows will usually be slight. The chance of falls or slips will be least with horizontal or vertical rocks, and greatest with rocks dipping between 35 and 70° or thereabout. Of course, allowances must be made, in reaching conclusions, for variations in the thickness of the individual beds, and for differences in the tightness or openness of the bedding planes.

CONTACT PLANES.—All of the features which characterize ordinary bedding planes are emphasized on those planes where two different kinds of rock are brought into contact. The chance of slipping and the possibility of water troubles are both present at such points. This is true even where the contact is an ordinary conformable one, both rocks having the same dip; it becomes still more important where the contact plane is marked by faulting.

FAULT PLANES.—Since the existence of a fault implies that there has been movement along its plane, the rocks on one side having been raised or lowered relatively to those on the other side, it can be seen that the fault plane and the zone of rock in its immediate vicinity are likely to offer engineering difficulties. When fracturing or brecciation of the rocks has accompanied the faulting, the effects may extend over a considerable zone, and their technical importance may be heavily increased. But even where there is no serious rock fracturing, the fault plane itself offers opportunities for easy rock movement, which may vary in intensity from simple roof falls to serious slips. And, in addition, the plane of the fault is likely to offer an easy passage for surface and subsurface waters.

For these reasons, a faulted zone is not likely to give cheap and safe tunnel driving, or cheap maintenance, and if it is possible to detect the presence of fault in advance, and locate its position on the ground, it will pay to go to considerable trouble to avoid its neighborhood, by shifts in either alignment or level.

The Reclamation of the Zuider Zee

By J. M. [illegible]*

The long contemplated reclamation of the Zuider Zee, the inland sea reaching into the north coast of Holland, was just about to be started when the present European War broke out. Whether it is to be carried out now or whether it is to wait for another 20 years while Europe regains its balance, it remains a most interesting engineering problem. The first complete plan for the project was made in 1866, and this was supported by the government to the extent of appointing investigating committees in 1870. There followed then a series of plans culminating in those of 1877 and 1891,[1] since which time the project has been constantly growing in favor until on September, 1913, the Government announced its intention to begin the work along the plans suggested in the 1891 report, with the necessary modifications of detail. This final scheme will be described below.

*[illegible]

[1]See "Engineering News," [illegible]

Details of Scheme

The Zuider Zee (Fig. 1) covers a total area of 2600 sq.mi. The plans approved by the Government provide for a main dike across the mouth of the sea, with a number of subsidiary dikes inclosing 770 sq.mi. of "polders,"* which will be drained and used for agricultural purposes. Between the polders and the main dike is to be formed a fresh-water lake of 800 sq.mi., to serve as a reservoir for the Yssel River.

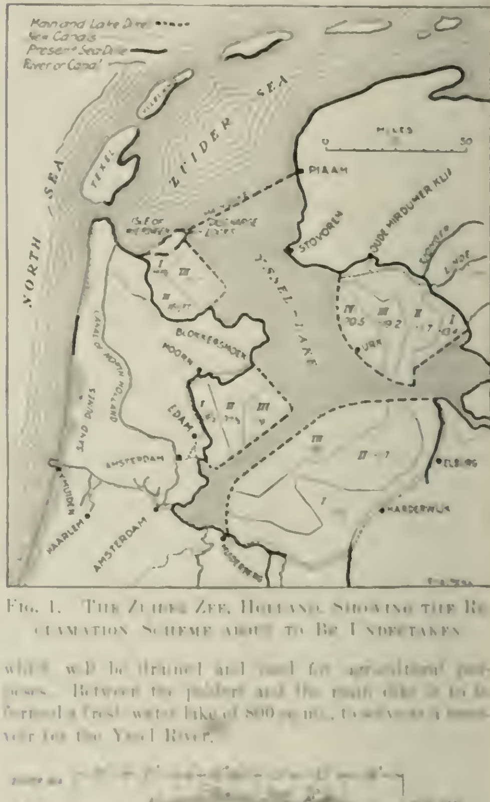

Fig. 1. The Zuider Zee, Holland, Showing the Reclamation Scheme About to Be Undertaken

Fig. 2. Section through Main Dike across Mouth of Zuider Zee

The main dike, separating the lake from the sea, will have a length of 18 mi. and an average width of [illegible] ft., with a height of 17 ft. above the Amsterdam water mark (Fig. 2). This dike will be in water of an average depth of 16½ ft. below Amsterdam water mark, while the deepest place will be as much as 20 ft. below that datum.

Thirty-three years will be required to complete the work, at a cost of $[illegible], not including the interest, or $[illegible], including the interest. Instead of the present annual revenue of $[illegible] derived from the Zuider Zee fishing industry, it is estimated that agriculture will yield a revenue of about $[illegible] annually.

*Polder, a Dutch word which has been anglicized and which is defined as "a tract of low land reclaimed from the sea by dikes."

Main Dike

The main dike will connect Ewykslnis, in the province of North Holland, with the Island of Wieringen, and from there will go northeast to the little city of Piaam, in the province of Friesland. The deepest channel is 35 ft., between Wieringen and North Holland, while the deepest place between Wieringen and Friesland is 20 ft. It is planned to construct a little island of brushwood, revetment, and stone half-way between Wieringen and Friesland on the sandbank Breezand, with a berm of 250 ft. The connection of this island with the coasts of Wieringen will be the next undertaking.

The dike is to be constructed with its toe against a dam (Fig. 2), a necessary means to assure the best possible footing for so long a dike. This dam, which will be built in layers, will have its crest at low-water mark. The toe will assure a solid footing for the main dike, which, with the layer of stones and the anchoring with piles, makes it impossible for it to wash away.

The base of the toe dam will be approximately 100 ft. On and against this dam will be built the actual dike, with sand which will probably be dredged from the Zuider Zee. The outer slope, 1 on 4, will have a solid stone paving up to a height of +15½ ft. A. P.; then a layer of clay 3½ ft. thick to the top of the dike, which will have a width of 7 ft. Then will follow the first inner slope, 1 on 2½ (no stone covering), a driveway of 23 ft., a double-track railroad requiring a width of 33 ft. and a second inner slope 1 on 3, having a heavy stone paving and a 3½-ft. layer of clay to 1 ft. 4 in. below A. P., the adopted water level of the Yssel Lake.

In building the main dike, it is proposed to first fill up all the lower part; which preparatory work of evening up the bed of the dike should be accomplished without any difficulty. The sand being dumped out in large quantity at several places at the same time, will fall with its natural slope forming a very wide base, which certainly will increase the solidity of the foot of the dike. Two continuous layers, forming a so called sinkplate, will anchor the base permanently. Then while the dike is being built up on top of this anchored base, the outside scope will be protected against the onrushing waters of the sea with large stones.

The most difficult part will be in the meeting of the four dikes, built from the temporary island half-way between Piaam and Wieringen, to either side, and also from Wieringen and Piaam toward that island. When a certain opening is reached, the head ends of these dikes will be protected by a massive concrete block. The next problem will be the placing of a number of concrete boxes measuring 160 ft. long by 16 ft. wide and 16 ft. high, about 115 ft. apart. These boxes, which will be made with partitions, will be towed to the proper place, then filled with sand, and in this way lowered to the bottom. Sand will be deposited on both sides. The weight of each will be approximately 2000 tons. In this way the opening will be reduced by about 50%. A second row of concrete boxes of the same dimensions will be deposited beside the first ones, but in such a way that they cover the open spaces of 115 ft. left by the other row of boxes, and also overlap about 7 ft. on each side. In this way, by means of this massive row of concrete boxes, the opening between the dikes will close up.

In order to prevent the forming of dangerous rapids when closing the last few openings, it will be necessary to wait for a very quiet day to close up the last twenty or so openings, and even then it is very doubtful if the remaining opening between the dikes can be filled up in one season. A great many concrete boxes will have to be used, and there is a possibility that the closing up of the opening will not be completed before fall and winter set in, which may result in the wrecking of some of the work. But once the concrete blocks are all set in their right place, the completion of the remainder of the dike is merely a matter of time.

Polders

There will be four polders within the dike. They will be known as the Northwestern Drainage or the Wieringer Lake, with an area of 80 sq.mi.; the Southwestern Drainage or Hoornsche Hop (120 sq.mi.); the Southeastern Drainage (405 sq.mi.); and last the Northeastern Drainage (195 sq.mi.). Each will be subdivided into smaller areas, as shown in Fig. 1, with varying depths for each subdivision. These subpolders, as one might call them, will be separated by dikes or quays, with locks where various canals intersect these quays. This division has a great advantage, in that it will be possible to first drain the most shallow subpolders and get them properly treated and prepared.

Each subpolder will have its own steam pump, the capacity of each being calculated as follows: 12 hp. per 1000 hectares (2470 acres) for each meter (3.28 ft.) lift (approximately 1.15 hp. per 1000 acres for each foot lift). Considering the fact that the water must be pumped up to 16 in. above the normal water mark of the new lake, the combined power of the various steam pumps for the four main polders will be approximately 17,000 hp. These pumps will have to be kept in perfect condition at all times, owing to the fact that they must do continuous duty, especially during the rainy season in spring, in order to keep the level of the various canals of the subpolders up to the proper height. The total area drained will be 800 sq.mi., of which 725 sq.mi. is first-class clay ground. Fifteen steam pumps will be required, one for each subpolder.

A fresh-water lake will be formed within the dike, known as the Yssel Lake, thus solving the hard problem of what disposition to make of the River Yssel, which will flow into this lake. Thirty discharging sluices, each having a width of 33 ft., will form the connection between the lake and the Zuider Zee. It is proposed to build a discharging canal, 3200 ft. wide, at the east end of the Island of Wieringen, increasing to 3930 ft. at the Zuider Zee side, with a depth of 16 ft., while near the Yssel Lake, the width will be 1875 ft. At the Zuider Zee end, there will be located five groups of six discharging sluices each, with lock sills at a depth of 13 ft. below the water mark of the lake. Besides this discharging canal, there will be a canal 500 ft. wide, with two locks, one 35 ft. wide, and the other 20 ft. wide. The size of the lake is calculated to give ample storage room for Yssel water even if high seas and a high river level render it impossible to open the discharging sluices, for three days, a combination of circumstances which is not likely to occur.

The dikes along the lake, which will not be of such massive construction as the main dike, will have their crests at from +8 ft. A. P. to +11½ ft. A. P.

A very careful examination of the water level of the

Zuider Zee was necessary before it was possible to place the proposed normal level of the Yssel Lake at −16 in. A. P. Of course, it will not be possible to always keep the water level to the normal mark, because of various natural conditions, such as high winds or unexpected high water in the River Yssel, but the variation will never amount to much. It will always be possible to prevent a lower level than the proposed by a well regulated valve system in the discharging locks.

New Canals

On account of the location of the main dike and the four main polders, it is necessary to provide for new discharge canals in a few provinces. These are shown on the map in Fig. 1.

Benefits of Scheme

Navigation on the Zuider Zee will be greatly benefited by the diking, as the proposed water level will insure a level high enough to make navigation safe. It will also be a great benefit by facilitating the discharge of most of the rivers and polders, which in some depends entirely on a low level of the Zuider Zee, with the result that these are overflowed during high water, and are damaged by the Zuider Zee water which is harmful to grass land. Then again, in the course of a few years, the Yssel Lake will have fresh water, which will mean that the small streams and canals will also contain fresh water, especially in Friesland. Furthermore, there will be a short railroad connection between the northern part of North Holland and Friesland.

The main gain will be a very fertile piece of ground with an area of approximately 8[illegible] sq.mi. Figuring about ¼ sq.mi. for one farmer and his family, this new province will give homes to not less than 10,000 families, or about [illegible] people. To this can be added about [illegible]% to take care of the tradespeople of various classes, doctors, teachers, etc., who will make this new province their home. In all, this reclaimed land should furnish homes for between [illegible] and 100,000 people.

It is calculated that the main dike will be completed in 9 years. From the fifth to the ninth year, improvements will be made on several harbors, and the Zuiderzee dikes with the two draining locks, as well as the canal from [illegible] to Harlingen in the province of Friesland will be completed.

In the 15th year, the Northwestern Drainage will be completed, in the 2[illegible] year, the Southeastern Drainage, some years later the Southwestern Drainage, and in the 32nd year, the final work on this great project will be finished. The government, however, will hold the reclaimed land for two or three years before leasing it out to farmers.

A Large Hand-Built Earth Dam, "Mammoth Reservoir," Price, Utah.

By [illegible]*

Mammoth Reservoir, which supplies the [illegible] water for the Price River Irrigation Co.'s [illegible] in Carbon and Emery counties, Utah, is situated in San Pete County, 3[illegible] miles east of the town of [illegible], and is up in the mountains at an elevation of [illegible] ft. above sea level. The basin in which the waters are impounded, lies in the apex of the Wasatch mountains, at a point where this range forms the divide between the Great Salt Lake basin and the Great Colorado River watershed, and of which stream the Price River is a tributary. The waters released from this reservoir travel down Gooseberry Creek 24 miles to the town of Colton, on the Denver & Rio Grande R.R., and thence down Price River to the diversion dam, some five miles above the city of Price.

Dam Site—The dam, which is being constructed to impound the waters of Upper Gooseberry Creek, is located in a cañon, the side slopes of which are composed of a glacial flow. The clay and rocks seem to have moved but a short distance as the rocks are worn but little and ledges of some extent are almost intact. The clay and fine gravel have formed a soil covering on the cañon slopes and is of fine quality for use in the construction of an earthen dam. The bed rock is found only a few feet below the bed of the creek and upon this the discharge tunnel, 5x7 ft. in section, was built, connecting the feeding tower in the reservoir with the creek on the downstream side of the dam.

General Design—The dam is designed to be 125 ft. in height, eventually, and is built of earth on both sides of a concrete center core wall. The core has buttresses on both sides opposite each other, starting 20 ft. wide at bed rock and tapering on a batter to zero at the top of the dam, and spaced 20 ft. apart along the wall. The dam is being built only so fast as the irrigation demands of the farming district require; it has been six years under construction; and, is now at the 67-ft. level. The present area of the dam covers [illegible] of an acre.

Peep Wells—Two peep wells, composed of 7[illegible]-in. casing pipe, are carried up through the dam, one on the upstream side of the core wall and one on the downstream side, each about 6 ft. from the core and near the center of the dam. The bottom end of each starts at about the 30-ft. level. They were started by placing a pad of sand and gravel of the proportions for concrete but without the cement or water. This pad was made 1 ft. thick by 6 ft. square on the earth dam. A grillage of ½-in. rods, 3 ft. long, was laid on this pad, the rods being set 2 in. apart. Upon this grillage, the open end of a section of pipe was set, the top being braced in a vertical position; then, as the earth was spread up the next lift, the pipe was filled with the sand and gravel to about 1 ft. above the lower end. From this point on, the earth was tamped up to the outside of the pipe the same as on any other portion of the work. These wells will be carried to the top of the dam, and each will be fitted with cap and float. These wells are designed to indicate the line of saturation in the interior of the dam.

Springs—Several springs were encountered during construction. Those in the bottom of the gulch were tapped with concrete and the water conducted to the outlet tunnel in tile pipe, while those encountered up the hill slopes were excavated so the cavity could be filled up with gravel, capped with concrete and conducted in [illegible] drains laid in trenches in the natural hill ground and carried out below the area covered by the dam. Those springs which developed on the upstream side of the core wall were conducted to and through the core wall in a concrete-covered gravel filter, and thence to the outlets, as above described.

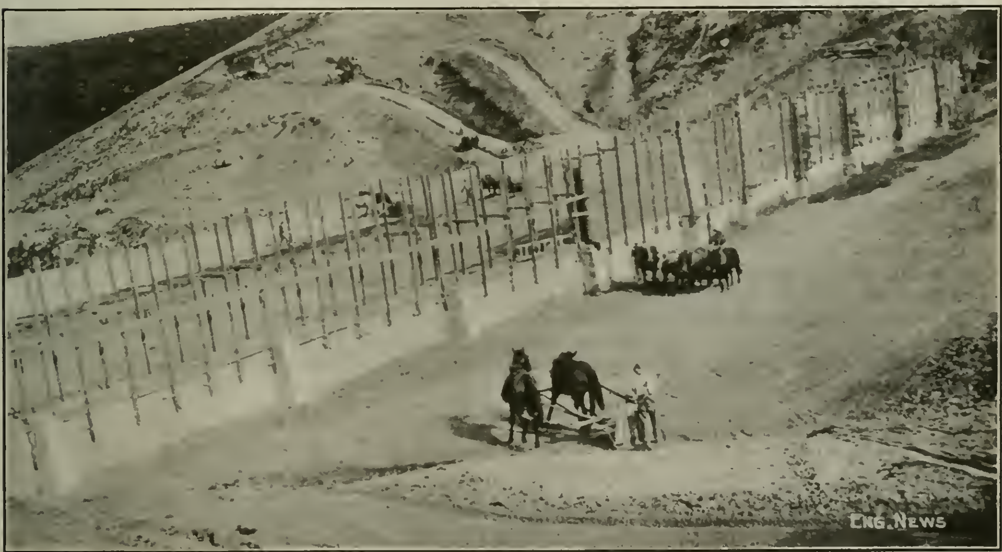
*[illegible]

EARTH FILL—The first work on the earthen fill was carried to the 15-ft. level by dump wagons, the earth being rolled with a corrugated roller of eight tons weight, drawn by four horses. The next 25 ft. was carried on by water. A ditch carried water along the brow of the hillside 150 ft. higher than the work. Teams and plows would make furrows straight down the hill slope from the ditch to the work level on the dam. A small quantity of water released from the ditch into the furrow washed the entire furrow upon the dam, while the teams were coming back up the hill to engage another furrow. The free water was carried off the work in an improvised culvert through a dike at the extreme up- and downstream faces of the dam, which was carried a few feet higher than the puddled lobe and thus impounded it. This method was found objectionable because the heavy and coarser material, weighing 2100 lb. per cu.yd., dry, would repose next to the hillside, while the very fine clay, weighing 1500 lb. per cu.yd., dry, would carry in suspension to the center lobe of the work. It was found so difficult to extract the water from this fine clay that the sluicing process was abandoned and rock and gravel were thrown into this puddled and bottomless mass from the edges until men and teams could travel over it. The work is being finished by the use of scrapers and wagons.

CORE WALL—The core wall is built up in 10-ft. levels ahead of the earth work. First the materials are brought upon the work and are distributed along a strip of the dam about 20 ft. wide next to the wall. Then the forms are erected, a steam concrete mixer is brought on and a platform is built at intervals of 100 ft. The concrete is pulled up an inclined plane, by horses working on a block and tackle system. Three-wheeled cars are used, holding 1 cu.yd. of concrete, and these are dumped over the edge of the forms into place.

OUTLET TOWER—The circular tower, or valve pit, is erected at the upper end of the outlet tunnel and is made of concrete reinforced with heavy steel bars and rods. The tower is 6 ft. in diameter inside of a 24-in. wall. A system of valves, 28 in number, is being built into this tower spaced vertically and horizontally to give a helical course up from the bottom of the tower and in order that every one can be operated from the top of the structure when this is completed.

The tower is up to the 67-ft. level now, and has been constructed by the use of a trestle work extending from the hillside at the regular 10-ft. levels. At this level the trestle was so high that when the reservoir is filled, each spring, the timber work attempted to float. This work therefore has been taken down and built into a circular barge. The tower will be erected to the yearly 10-ft. levels from this barge while the reservoir is full in the spring. The barge will lower with the surface of the water as the same is drawn out and will rise to the upper level the next spring when another 10-ft. level will be built.



CONSTRUCTION WORK UNDER WAY AT "MAMMOTH RESERVOIR" DAM, PRICE, UTAH

ORGANIZATION, ETC.—This is an example of doing work under difficulties, yet the work does not suffer in consequence. The dam should be of interest as one of the largest earthen dams in the United States, and as it is being built without any modern machinery, except the smallest steam concrete mixer made. A 12-mile dug-way through a precipitous cañon renders the hauling of heavy freight very difficult. The roller was cast in seven sections so that, with the frame, eight loads could be made of it.

The earth fill is costing 38c. per cu.yd., and the concrete $9.87 per cu.yd. The overhead charges are very nominal.

The work is visited annually by the State Engineer and the State Land Board. The report of the State Land Board after a recent visit to this dam went so far as to say that this work was, without question, the best of its kind in the State of Utah.

The New York Rapid Transit Railway Extensions*

By F. Lavis†

III--General Arrangements for Construction

The Operating Contracts

[illegible] the original contract‡ for the present subway provided for its construction by the city or with the city's money, its equipment of power stations, electrical apparatus, signals, telephones, rolling stock, etc., being furnished by the operating company, which had a lease for 50 years, with privilege of renewal for 25 years. Contract 2, Brooklyn extension, 35 years and 25 years. These two contracts with the renewals would, therefore, run to 19[illegible] and 1965, respectively. The operating company was to pay a rental sufficient to cover the interest and amortization on the bonds issued by the city in payment of the cost of construction. At the end of the lease, the city to own the structure free and clear, with the right to purchase the equipment.

The elevated lines in Manhattan have a perpetual franchise, so that under the new arrangement, the lease for the extensions to these lines and the third tracks was made to run for 85 years, and is not included in the agreement covering the other lines, which is as follows:

By the terms of the new contracts, the leases of all the *new* lines as well as those of the existing subway are to run for 49 years from Jan. 1, 1917, and provide that the city shall share in the profits of operation, which are to be determined in the following manner:

The revenues of all operated lines of each system will be pooled, the two companies will be allowed to retain all the earnings (after payment of rentals, interest, amortization, etc.) on the lines they now operate, and the city will share in the profits of the rest. The contracts provide for quarterly settlements, which will provide for the following payments:§

1. To the city (in the Interborough contract only) rentals now received [illegible]

2. Taxes and governmental charges of every description [illegible] with the system.

3. All [illegible] in the operation of its system.

4. Twelve per cent. of the quarter's revenue for maintenance exclusive of depreciation. "Maintenance" shall include repairs and replacement of [illegible], but not the replacement of [illegible] equipment. If the maintenance cost in any quarter [illegible] shall be less than 12 per cent. of the revenue the unexpended balance shall go into the depreciation funds and if [illegible] excess occurs, it may be withdrawn from such funds.

5. (Interborough Contract). For the first year of operation an amount equal to 5 per cent. of the revenue for depreciation of such portions as are not repaired or replaced through expenditures for maintenance. Two depreciation funds are established—one for the existing subway, and one for the new lines, and they will be under the control of the Depreciation Fund Board. Depreciation for future years to be agreed upon.

5. (Brooklyn Contract). For the first year of temporary operation an amount equal to 3 per cent. of the year's revenue for depreciation of such portion of roads and equipment as are not repaired or replaced through expenditures for maintenance. This amount for each year will be paid into three depreciation funds—"Depreciation fund for the railroad and equipment," "Depreciation fund for the plant and property of the extensions and additional tracks," and "Depreciation fund for existing railroads." Such funds shall be under the control of the Depreciation Fund Board. Depreciation for future years to be agreed upon.

The Depreciation Fund Board is to consist of three members—one to be chosen by the company, one by the Commission and the third by both jointly, or in case of failure to agree, by the Chief Judge or an Associate Judge of the Court of Appeals, or by the President of the Chamber of Commerce.

6. (Interborough Contract). One-quarter of the sum of $6,335,000 to be retained by the company as representing the average annual income from the operation of the existing railroads.

6. (Brooklyn Contract). One-quarter of the sum of $3,500,000 to go to the company as representing the average annual income from the operation of the existing railroads during the two years prior to the beginning of [illegible]

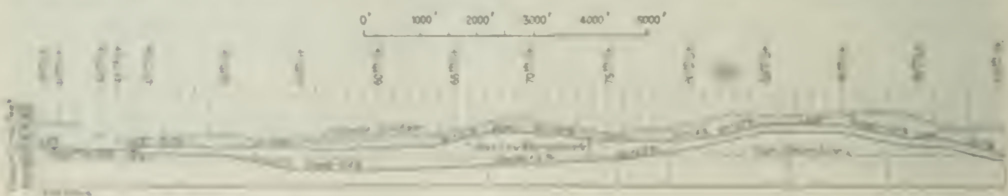


Fig. 7. Profile of [illegible]

[illegible] out of which the lessee shall pay interest charges on obligations representing the capital investment [illegible] the date of this contract) on the existing [illegible]."

7. One-quarter of an amount equal to 6 per cent. of the company's contribution toward the cost of construction and equipment for initial operation. Out of this payment the company [illegible] sufficient, with interest and [illegible], to [illegible] within the terms of the lease such [illegible] cost.

8. If additional equipment is provided an amount to be retained by the company equal to one-quarter of the annual interest payable by it upon the cost of such additional equipment together with a sum equal to ¼ of 1 per cent. for the amortization of such cost.

9. (Interborough Contract). If the company shall share the cost of construction of additions to the [illegible] system, an amount equal to one-quarter of the annual interest payable by the company upon its share of such cost, together with ¼ of 1 per cent. for amortization.

9. (Brooklyn Contract). To be paid to the city an amount equal to one-quarter of the annual interest payable by the city upon its share of the cost of construction and ¼ of 1 per cent. of the city's share of such cost.

*Steel †Reinforced Concrete.

10. (Interborough Contract). An amount to be paid to the city equal to ¼ of 8.76 per cent. of that portion of the cost of construction paid by the city.

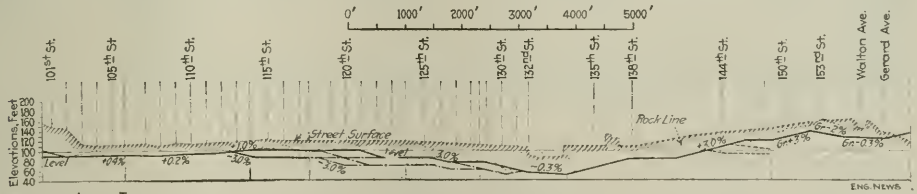
11. An amount to be paid to the city equal to one-quarter of the annual interest actually payable by it upon its share of the cost of construction of additional lines, together with ¼ of 1 per cent. for amortization.

12. One per cent. of the revenue to be paid into a separate fund under control of the Depreciation Fund Board to be invested and reinvested to provide a contingent reserve fund. When such fund equals 1 per cent. of the cost of construction and equipment, payments to it shall be suspended and interest on it shall be included in the revenue. If it falls below 1 per cent., payments shall be resumed until it again equals 1 per cent. This fund shall be used to meet deficits in operation and other purposes.

13. The amount remaining after making the foregoing deductions, shall be divided equally between the city and the company.

Route and Section Numbers

The custom was established in the days of the old Rapid Transit Commission of assigning a number to the various different routes proposed from time to time for new lines, and this has been perpetuated, as, for instance, the Lexington Ave. route is Route 5, etc. It seems hardly necessary, however, for the purpose of these articles to enumerate these in detail.



LEXINGTON AVE. LINE

For construction purposes, each route is divided into sections, numbered consecutively from the beginning and usually from the south toward the north in Manhattan and the Bronx, from west to east in Brooklyn. The sections vary considerably in length, but are generally about half a mile, and the bids so far obtained range from about $800,000 to $1,000,000 per section. The cost of structure and per foot of track is shown in the accompanying table, which also shows the per cent. of work completed on each section on Mar. 1, 1914, and the names of the contractors. The prices given in this table do not include station finish, such as tiling, stairways, ticket offices, railing, etc., or any track or equipment.

There is very little comment which can be made on these figures. The work is so varied that there is, as will be seen, a wide variation in the prices either per lin.ft. of track or per lin.ft. of structure. The Lexington Ave. line is perhaps fairly typical of normal conditions. (See profile, Fig. 7.) From 53rd St. to 129th St. the price is fairly uniform at about $225 per lin.ft. of track. Sections 9 and 10, however, have two tracks in tunnel which can be built with little or no interference with subsurface structures and no street

[illegible], and this is included in the lower price. Section 12 has a high price per lin.ft. of structure, as this, as will be noted later, provides for a very elaborate system of track crossings. Section 14 is the Harlem River crossing. The sections north of the Harlem, Route 5, Section 15, Routes 19 and 22, Sections 1 and 1a, where only part of the street is proposed to be decked and where the street cars are operated on the overhead trolley, show a considerable decrease in the cost per lin.ft., as do also the elevated structures on Jerome Ave. and White Plains Road.

On the down-town lines, Route 5 (Broadway), Section 1 involves the support of the elevated railroad structure; Section 1a the two reversed curves driven in tunnel; Section 2a the crossing of Canal St., where the underground conditions are very bad. The other sections, which are perhaps more nearly normal, show approximately an approach to the commonly accepted rough estimate figure of $1,000,000 per mile of track, built in subway.

Equipment

There has been no announcement so far of any change in type of rolling stock of the Interborough, but the B. R. T. has had a larger type of car designed, Fig. 9, providing considerably greater capacity, which will, it is thought, owing to the arrangement of the doors, permit

There have been many difficulties to overcome in connection with the design of these larger cars. Axle loads of 51,000 lb. cannot be exceeded, as this is fixed by the bridge department for the East River bridges. The motors are arranged one on each truck, instead of both on one truck, as on the present Interborough car, thus, of course, giving a better distribution of the weight and taking care of some of the increase in the weight of the body and number of passengers. The limitation as to the axle loadings could not be overcome by the adoption of six-wheeled trucks, even though their use were not prohibited by the sharp curvature, as this would only involve a heavier truck with practically the same concentration of load so far as the bridge structures are concerned.

Some important improvements are to be introduced in the equipment of the cars. The combined car and air-line couplers (described in Engineering News, Feb. 29, 1912) have proven very satisfactory, and in addition to these couplers a device is to be installed in the new equipment which will also permit the automatic coupling of the electrical connections (10 in all). The coupling and uncoupling will be entirely under the control of the motorman in the cab and be governed by an interlocking device so that the electrical connection cannot be made until the air-line coupling is complete and the

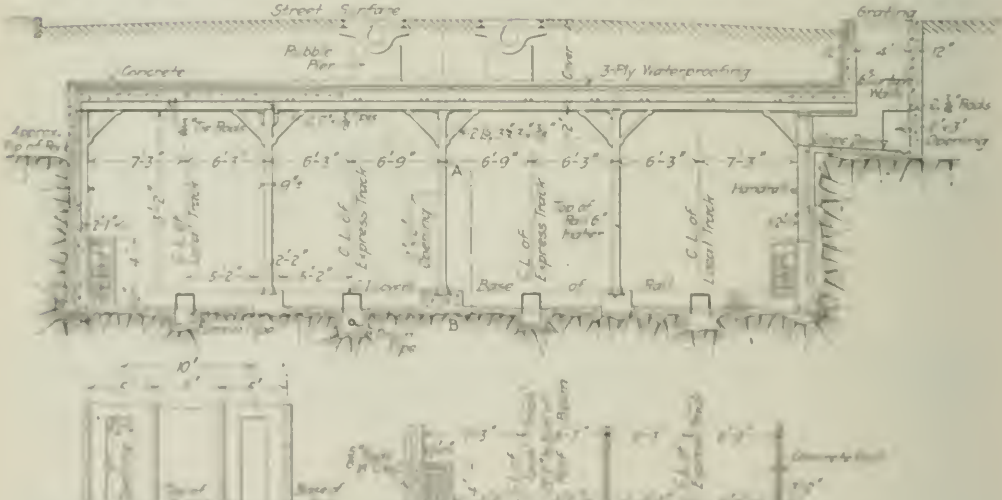


Fig. [illegible] Typical Section of Rapid Transit Subway on Seventh Ave. at [illegible] St.

[illegible] passengers and [illegible] that there will be no more delay in loading and unloading than there is with the small [illegible] now in use. The principal dimensions of these two cars are as follows:

	Interborough	B. R. T.
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]

[illegible]

brakes are under control. Similarly, to uncouple, the release of the electrical connection by the motorman permits him to release the devices so that the air and train couplings will part. It is hoped by these devices to materially decrease the number of accidents to men in coupling cars, and also to reduce the time and expense of making up trains.

Before the introduction of this automatic coupler the link-and-pin type had been in general use, but even with eight-car trains on the Interborough, the breaking in

two of the trains was frequent enough to show that the limit had been reached for this type of couplings. Automatic stops in connection with the signals are in use in the present subway, and the sudden setting of the brakes produces heavy stresses on the couplings. The new coupler has satisfactorily stood all the strains due to these causes, and the introduction of 10-car trains made it almost an absolute necessity. Electric pneumatic brake control will be used on the new equipment, insuring more nearly simultaneous action of the brakes on all the cars.

The signal to the motorman is given by the closing of an electric circuit when all the doors of the train are closed. This has been in use successfully for some little time already, and not only saves the delay due to transmitting the signal from car to car by hand, but also acts as a safety device in preventing the starting of the train while any door is open.

A species of weighing device has been introduced in connection with the air-brake system to maintain the same ratio of braking power on loaded and empty cars. As the car is stopped at the station, the variation in the load due to the discharge or receipt of passengers, actuates a piston in an auxiliary air cylinder, directly connected to the jam-cylinder. The variation in the position of this piston in the auxiliary cylinder regulates the volume of the jam cylinder, thereby regulating the effective pressure obtained from a given amount of air; thus when the car is fully loaded the volume of the auxiliary cylinder is at its minimum, and when the car is empty it is at its maximum. When the doors are closed it is automatically locked in this position until they are opened at the next station, thus preventing any change from variations in the loading due to the vibration and oscillation of the moving train.

A similar device is to be applied to the accelerating system. At present this has to be adjusted so that it will not slip the wheels of an unloaded car. With the proposed device, however, it will be so adjusted that it will be increased under load.

By these various devices it is expected to save six minutes in time between 59th St. and Coney Island. Deceleration from 50 miles per hour will be accomplished at the rate of 3 mi. per hr. per sec. (on the emergency) as compared with the present maximum of 2 mi. per hr. per sec., and from the lower rates of speed at higher rates of deceleration, while acceleration will be at the rate of 1½ mi. per hr. per sec.

Comparison of this with some comparatively recent practice on electrified steam railroads is of interest.

N. Y., N. H. & H. R.R.—Multiple unit trains 1 motor 2 trailers acceleration 0.5 mi. per hr. per sec. Schedule speed from Grand Central Station to Mt. Vernon, 13½ miles, with 1 stop in 23 minutes.

Lancashire & Yorkshire R.R., England—Acceleration to 30 mi. per hr. in 30 sec. Schedule speed, 18½ miles with 14 stops in 37 minutes.

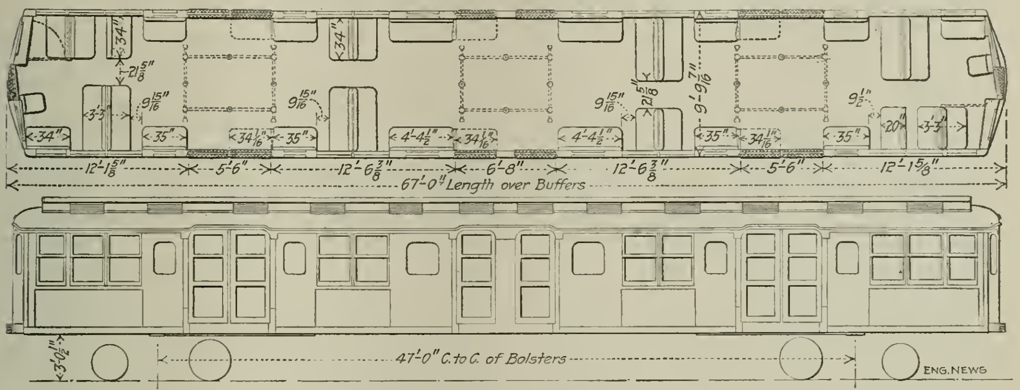

FIG. 9. DESIGN FOR STEEL CAR; BROOKLYN RAPID TRANSIT SYSTEM

POWER

Power for the Interborough system is to be furnished from the power houses at 59th St. and the North River and at 74th St. and the East River. The former, built to furnish power for the present subway, was originally equipped with nine reciprocating units with a total normal capacity of 7500 kw. each. This was increased later by the addition of five low-pressure turbines each having an additional capacity of 7500 kw. and using exhaust steam from the original units to a total of 105,000 kw. This plant is now to be enlarged by the addition of two 30,000-kw. turbine units, each unit consisting of a high-pressure high-speed set exhausting into a low-pressure low-speed turbine, making the total normal capacity about 165,000 kw.

The 74th St. power house was built only 13 years ago when the elevated lines were electrified, but owing to the rapid change and improvement which is continually taking place in electrical machinery and apparatus, part of this plant is to be replaced. The old equipment consisted of eight units (reciprocating) and one turbine unit of 7500 kw. each. Four of these are to be taken out and three turbine generators of 30,000 kw. each are to be installed, which, with the five old units remaining, will make a total normal capacity of 127,500 kw.

The contracts between the operating companies and the city call for an average speed on express tracks between main-line terminals of 25 miles per hour, including stops of 30 seconds at each intermediate station, and an average speed on local tracks between terminals of 15 miles per hour, including stops of 20 seconds at each intermediate station.

GRADIENTS AND ALIGNMENT

Unlike the location of steam railroads, the location of such lines as those under consideration is governed only to a comparatively small extent by questions of gradient or alignment as they affect economy of operation. The primary consideration, of course, is the general location of the lines through or under streets in those sections of the city where the service is needed. The second consideration is the location of the various stations, which, in the lower part of Manhattan (below 42d St.) are about five or six blocks (1000 to 1500 ft.), and in the outlying sections about 2500 ft. apart, and which is generally arbitrarily fixed by local conditions. Then the grades and alignment (within certain fairly wide limits) are made to fit these conditions. At present, owing to the fact that some sections of the line are not definitely designed, it is not possible to make an exact and complete statement covering the gradients and alignments of the whole system, but the following is approximately correct.

GRADIENTS—Gradients up to 3% may be considered normal, this upper limit being used with considerable frequency, though generally in comparatively short stretches. Some of the longest are nearly 1500 ft. in length, and in a very few cases 3% grades, as long as this occur as ascending grades immediately beyond a station stop on the local lines. There are gradients in excess of this up to 4.5%, and in one case where the Centre St. loop connects to the old Brooklyn Bridge it has been necessary to use 5.4%. The higher rates of gradient occur mostly in connection with the approaches to the East River Bridges or the tunnels under the rivers, the grades on the former being 3.4% on the three newer bridges and 3.75% on the old Brooklyn Bridge.

With electrical operation and especially with the dense traffic conditions which exist or which will exist on the Rapid Transit lines in New York, the question of gradients is not so important as it is in connection with the locations of railroad lines for operation by steam locomotives, or where continuous sustained effort is required on long supported gradients.

For short sections of heavy grade, extra power is supplied through an additional feed wire, or wires to the points where it is needed. The electric motor as is known can stand a heavy overload of as much as 100%, or even more for short periods, the amount of the load and the time which it can be carried being limited by the heating which takes place under these conditions. Short stretches of steep gradient are not, therefore, limiting or so important as longer ones would be. Considering the requirements for some reserve power for ordinary operation (which have to be fairly liberal on account of the great carrying capacity of the lines as well as the short distance between stations), it may be seen that the limits controlling the gradients which may be used are rather wide.

In the operation of self-contained motor cars also, there is the advantage over trains hauled by locomotives that all additional load increases the adhesion and, therefore, permits application of the power necessary to haul it. It must also be noted that the new motors are to be [illegible].

The general procedure has been that the gradients are fixed by local conditions within the limits given above, then the motors are designed to carry the load. Momentum is availed of whenever possible, where under normal conditions trains may be expected to utilize it in overcoming ascending gradients, and this can be quite safely done, because in case a train is stopped on an up grade, the motors can be relied to start it and move it along, even though at low speed, on account of their great capacity for overload. The original subway equipment was designed on a basis of about 60% motors and 40% trailers, but the tendency is toward the equipment of all cars with motors.

On the underground lines so far as possible, stations have been located at summits of gradients, both in order to get them as near the surface as possible and also that the ascending gradient may be utilized in braking, and the descending grade to help acceleration. While, however, these two purposes mutually help each other on the subway lines, and the rise and fall involved is, therefore, not an operating expense, this is not the case on the elevated lines. These latter, of course, must maintain a certain minimum elevation over summits, but the comparatively slight additional cost of longer columns is so little, that there is every inducement to avoid dipping down into depressions even, or perhaps especially, if stations happen to be located at such points, and it has seemed better to put in escalators or elevators than to drop the track grade down, involving braking on a descending grade and acceleration against an opposing grade.

In one instance at least, on the original subway (at 33d St. and Park Ave.) on the four-track section, the two center tracks, which are used for the expresses, are carried through on an even grade, while the outer two local tracks are raised up at the station. On the new lines the tracks generally all follow the same grade except on Lexington Ave., where the express tracks are located on a lower grade in tunnel through the hill; but here, on account of the necessity of having an express stop at some point as nearly as possible midway between 42d St. and 125th St., it was necessary to bring the express tracks up near the surface at 86th St., as shown in the profile, Fig. 7, which is very typical of the way local conditions absolutely control the profile. From an operating standpoint, of course, it would have been much better to have run all the way through the hill on the lower grade.

On account of the capacity of the electric motor for overload also, there is little necessity for, or benefit to be derived from, the compensation of grades for curvature, although it is not uncommon to find the heavier rates of gradient combined with quite sharp curvature, as for instance, at Vesey St. and Broadway, where there is a 4% grade on a curve of 200 ft. radius.

By reference to the profile of the original subway line (Eng. News, Feb. 25, 1904) it will be seen that much steeper gradients have been found necessary on the new routes than are used on the present line, but this, as is explained above, has virtually been forced by the conditions which have had to be met, which are more onerous in many cases on the new routes than on the old.

On the old line, the Broadway section had no gradient in excess of 1.5%, and the Bronx branch has 3% grades only at the crossing of the Harlem River and 3.3% just beyond where the line comes out on to the elevated structure.

In a way the profile given, Fig. 7, of the Lexington Ave. line from 86th St. to 138th St. may be considered fairly typical, though on the other hand, the Varick St.-Seventh Ave. line from the Battery to 42d St. has light grades

throughout its length, comparing favorably with the old line, with which it will connect at 42d St.

ALIGNMENT—The alignment, of course, is governed by the same considerations of the necessity of following the streets, and so far as possible, avoiding encroachment on private property. This is especially difficult in the lower part of Manhattan where the streets are narrow and crooked, and where it is especially difficult to turn the curves, so that in some instances, notably at St. Paul's Churchyard, at Vesey St. and Broadway, and also at 42d St. and Lexington Ave., it has been necessary to acquire easements under private property at considerable expense. On the new lines all stations are to be located on tangents, to avoid the difficulties found on the original subways with stations on curves.

On the present subway in which cars 51 ft. long and 9 ft. 0½ in. wide are operated, there are the following sharp curves:

	Ft. rad.
City Hall loop	147¼
Forty-second St. and Park Ave	180
South Ferry loop	191
Main express tracks	225

The outer rails on curves were elevated for speeds of 30 mi. per hr. with a maximum of 6½ in., and this practice is followed in designing the new lines, though in some cases the operating company has increased the elevation in the old subway to permit speeds of 40 mi. per hr., on some of the curves of large radius.

On the new lines 500 ft. has been considered the minimum radius for ordinary cases, 200 ft. the absolute minimum, except that there is one curve of 150 ft. radius. On the B. R. T. lines additional clearance has to be provided on curves to provide for the extra overhang of the larger cars, 67 ft. long and 10 ft. wide, which that company proposes to use.

Transition curves of a uniform length of 150 ft., irrespective of the degree of curvature are used, wherever it is possible to get them in. Crandall's formulas and tables are used. It may be noted that curves are usually laid out with radii of even feet instead of with even degrees of curvature.

CONTRACTS AND SPECIFICATIONS

GENERAL CLAUSES—The clauses of the specifications indicating the character of the work to be performed under each item or type of construction, will be discussed or quoted under each separate heading, together with the descriptions of the work. The general clauses of the contract and specifications where they differ from ordinary practice, or where they have particular applications on this work are briefly noted below.

The contracts are printed in pamphlet form, letter-size sheet (8x11). There is a table of contents at the beginning and a complete index at the end. Plans were published originally on large sheets about 22x30, lithographed and bound together, but this has been changed for smaller-sized plans which are lithographed on thin paper uniformly 11 in. wide, and bound into letter size (8x11) pamphlets the same as the contracts, thus making them very easy and convenient to handle.

The contracts for the general construction do not include any station finish of any kind, nor the track, ballast, or electrical equipment except such parts as necessarily have to be incorporated in the main structure, such as conduits for electric wiring, power cables, etc., and the ducts or pipes for lighting wires at the stations. The automatic pumps at the pumping stations are included as, of course, the drainage has to be taken care of from the beginning. The contract drawings usually include enough plans showing the general scheme of station finish, so that the contractor may have this as a guide in carrying out his work and that he may make due allowances for it. All necessary changes in location of sewers, water and gas pipes, electrical conduits, etc., required by the construction of the subway are included in the contract, the principal changes of the larger structures are shown on the plans, but exact details of smaller pipes, conduits, etc., are left until the existing pipes are uncovered, and all subsurface structures definitely and exactly located.

Approximate quantities of each item are given for the purpose of comparing the bids on a basis of total cost. The time may be extended or diminished if there is any material change in total quantities.

There are provisions calling special attention to the necessity of compliance with state and city laws, especially the eight-hour law and the requirement that contractors shall pay the union scale of wages.

As the work is to a large extent to be carried out in residential districts, there are provisions which give the engineers adequate control of night work of any kind which might disturb people living near the line. Blasting is not permitted between the hours of 11 p.m. and 7 a.m. There are strict provisions (regular city ordinance) for the storage of explosives, the maximum capacity in any magazine being 250 lb., and in most of them not over 100 lb.

BOND—A certified check for a stated sum, varying from \$10,000 to \$25,000, according to the size of the contract, is required with all proposals and a bond of a stated sum of approximately 10% of the amount of the contract from the accepted contractor, 15% is retained from the monthly payments up to a total of about 10% of the amount of the contract, after which only 10% is deducted.

TIME—The following clause is of interest in the provision for completion within the specified time:

> In the event of delay . . . . . the city . . . . . shall be paid damages for such delay. Inasmuch as the amount of such damages will be extremely difficult to ascertain, especially in view of the fact that the railroad herein contracted for is only a part of a complete system, the remainder of which is to be constructed under other contracts, it is hereby expressly agreed that damages shall be liquidated and paid by reducing the price to be paid the contractor as follows:

The provision then is for the retention of 1% of the amount due for the work done in the first month, after the time elapses, 2% for the second month, and so on.

The following "blanket" clause is of interest in connection with works of large magnitude, where the subsurface conditions are as uncertain as they may be in a city:

> The specifications and contract drawings hereinafter mentioned and taken in connection with the other provisions of this contract, are intended by the Commission to be full and comprehensive, and to show all the work required to be done. But in a work of this magnitude it is impossible either in advance to show all details, or precisely to forecast all exigencies. The specifications and contract drawings are to be taken, therefore, as indicating the amount of work, its nature and the method of construction so far as the same are now distinctly apprehended. The railroad is intended to be constructed for actual use and operation as an intraurban railroad of the highest class, adapted to the necessities of the people of New York, in the best manner, according to the best rules and usages of railroad construction, and in the event of any doubt as to the meaning of any portion or portions of the specifications or contract drawings, or of the

[illegible] of the contract, the same shall be interpreted as calling for the best construction, both as to materials and workmanship, [illegible] under the then [illegible] conditions. All the [illegible] of the specifications and all the terms of the contract [illegible] are therefore to be [illegible], construed and interpreted as [illegible] to [illegible] the [illegible].

MONTHLY ESTIMATES—The engineer shall make an estimate of the amount and value of the work done as [illegible] shall be just and [illegible], but shall not necessarily be [illegible] by the unit prices contained in the contractors' proposal, and provided that such estimate shall be withheld [illegible] if in the opinion of the engineer the work is not proceeding in accordance with the contract.

An allowance is made for structural steel delivered, at the rate of $40 per ton.

The contracts provide that the city shall make payments on estimates within 30 days after a certificate is issued by the commissioner. As a matter of fact, payments are usually made within 30 days of the end of the period covered by each estimate. Final payments are to be made 30 days after the filing of a certificate of completion.

SHAFTS AND OPENINGS—Plans showing the location of all shafts, plant to be erected in the streets, supports of street decking, openings in decking, etc., must be submitted to the engineers, and receive their approval before work is commenced. This, of course, in addition to the regular permits to be obtained from the city.

LIABILITY—The contractor admits (under the form of contract) that if the work be done without fault or negligence on his part that the plans, etc., do not involve any danger of foundations, walls, or other parts of adjacent buildings, etc.

Soldiers of Peace

BY LESTER C. G[illegible]*

[illegible]

In the heart of the sunny Southland
  Where the sultry breezes sigh,
The song of their panting dredges
  Flings [illegible] against the sky,
And the lazy water gurgles
  As it [illegible] at its earthen chains,
As the levee walls rise [illegible]
  A guard for the sheltered plains.

Through the everlasting mountains
  Their pounding rock drills bite,
And the yawning tunnels open
  To the smash of their dynamite,
Or a water pathway lengthens
  O'er the brink of a great divide,
Where their huge locks [illegible]
  Up the frowning mountain side!

On the floors of the [illegible] waters
  Through the [illegible]
Seeking their steel-shod [illegible]
  To the yieldless rock beneath,
Digging down through the [illegible],
  Fighting the flood [illegible]
Till the bridge piers [illegible] the torrent
  And carry a pathway there!

When the flickering shadows lengthen,
  And the glowing embers [illegible]
Their toil-scarred veterans gather
  On many a lonesome trail,
Snatching a moment's freedom,
  Ere break of [illegible] dawn,
With a thought of the deeds of [illegible],
  A sigh for their comrades gone.

On the stretches of far Alaska,
  On isles of the restless deep,
On the prairies of Central [illegible],
  Their unknown heroes sleep,
Where the Congo seeks the ocean,
  By the Orinoco's [illegible],
'Neath the skies of a hundred nations,
  Slumber their nameless dead.

By a boiler's wild explosion,
  By the [illegible] feathered dart,
'Mid the [illegible] of twisted girders
  When the great bridge trusses part,
By the burn of the [illegible] fever,
  With a [illegible] on the pale lips [illegible],
A curse that their work is finished,
  A prayer that the job goes through!

[illegible]

Eastward across the [illegible]
  Where the Old World [illegible] lie,
Westward [illegible] the mountains
  That [illegible] the sky,
[illegible]
  In the [illegible] light,
The Soldiers of Peace are fighting
  Their never ending fight.

Editorials

Opportunities for Engineers

Those of our readers who find themselves open for professional engagements on account of the war and its backfire in American financial circles, might move to Detroit. If their experience has been along mechanical lines, with an effective disguise in speech and appearance, they should be able to get from $5 a day up as a cog in the Ford machine. If, on the other hand, their training has been structural, a few weeks' study and labor should make them eligible for membership in the local bricklayers' union and then their fortunes would be made. Just now ordinary bricklayers in Detroit are being paid $1 per hour and on one sewer job—a good clear free-air 10-ft. tunnel —bricklayers are drawing $10 per shift, which rarely exceeds 8 hours and is sometimes much less.

Safety First at the Elevator Door

In our last issue we commented on the excellent work being done in the promotion of general public safety by the American Society of Mechanical Engineers through its efforts to draw up standard specifications for the construction and operation of steam boilers and to formulate a model state boiler law. It seems worth while to point out another field where concerted action by some equally disinterested association would be productive of almost as great public benefit. We suggest that provision for increased safety in the construction and operation of elevators be similarly studied—though not necessarily by this same society, for there may be others in even better positions to take up such a work.

Our attention is repeatedly called to the needs in this field by various insurance bulletins on industrial accidents, where the comparatively large number of elevator accidents are noteworthy. For instance, a statement before us of the Fidelity & Casualty Co., gives statistics of individual accidents during July, 1914. There were 66 elevator accidents during the month, but only 16 boiler explosions and 5 flywheel mishaps. Thirteen falling elevators caused the death of 3 persons and the injury of 31; 12 people were killed by falling down elevator shafts and 12 were injured; there were 31 accidents in which 9 persons were crushed to death and 22 were injured by moving elevators.

Study of such figures confirms the opinion that a comparatively high degree of protection has been secured against serious accidents due to the fall of elevators, since the number of cases is small and the casualties not severe. The figures do show, however, that great risks still prevail at elevator-shaft doors and elevator gates. In a year, upward of 200 people are killed at these danger points and upward of 300 are injured. Any engineer who has attentively observed elevator operation in New York City, which offers a good chance of intensive experience, must have been impressed with innumerable cases of unlatched and unguarded shaft doors and failures to provide or use safety gates on the car openings. Here then seems to be an important field for the "Safety-First" enthusiasts.

A Chance for Economy in Public-Utility Service

Why should gas-, electricity- and water-supply and even telephone-service companies continue to send out bills every month, or twelve times a year, when quarterly meter reading and billing, or only four times a year, would save from 25 to 40% of the amounts of the smallest bills rendered and from 10 to 15% of the annual cost of serving a very considerable proportion of its patrons? This question is naturally raised by the letter published elsewhere in this issue, criticizing the Cleveland Municipal electric plant and our recent analysis of its probable operating results. The writer of the letter calls attention to the small consumers who do not use enough current at times to make their bill equal the minimum charge imposed, and argues that they do not really have the advantage of the low rate advertised. This effect has been incidentally noted by commissions and courts, and in one case the Ohio Supreme Court held that minimum charges were illegal because they brought unit prices to small consumers above the limit fixed by franchise.

That such a large saving as we have noted above is possible on much of the business of gas, water and electric companies may be shown by a few figures. In 1909, the Massachusetts Board of Gas & Electric Light Commissioners inquired into the minimum monthly charges of the Boston Edison Co., and the company submitted the following as its actual cost per month of supplying each consumer paying the minimum rate:

Meter interest and depreciation	$0.232
Testing and repair	0.064
Meter reading	0.035
Accounting, billing, postage and stationery	0.245
Energy supplied (4.5 kw.-hr. at 3c.)	0.135
	$0.711

In 1912, the New Jersey Public Service Commission inquired into the monthly minimum rates of the Public Service Corporation and made up from the books of the company the following table of monthly costs per customer:

Meter and connection interest and depreciation	$0.295
Meter and connection maintenance	0.112
Distribution expense	0.090
Indexing meters	0.023
Office salaries and expenses	0.225
Expense collection	0.055
Expense	0.065
Energy loss in transformers	0.090
Energy supplied (6 kw.-hr. at 3c.)	0.180
	$1,135

In both tables the last item has been added from data accompanying the tabulation and assuming a total cost of energy alone at the customer's premises of 3c.

In the case of the Boston company 28c., and in the case of the New Jersey company 37c. represents the actual cost per month of meter reading, billing, etc. These items could be reduced to one-third this amount by reading the meters and rendering the bills quarterly instead of

monthly. The total annual saving per customer in these cases would range from $2.25 to $5. Besides this saving to the company, there would be an additional saving to the customers in postage and time in paying bills, which would add a considerable amount to this total.

It is argued that the companies must make monthly collections to meet their current expenses. But labor is the one important item which is really paid for in cash. Fuel and other supplies going into operation and maintenance are generally purchased on credit, running as high as 90 days. It would seem quite fair if the payments from the customers could justly be made to correspond with the payments which the company has to make—semi-annually in the case of interest and up to quarterly on supplies, especially if rate-basis valuations carry a certain amount of working capital to cover payments between quarterly collections.

By cutting down the cost of collection, the minimum charges and effective rate prices can be lowered to attract the small customers who are desirable additions if they pay their cost, since they increase the diversity of load and the popularity of service. It is a matter of recorded experience that the generating capacity needed to carry the small electric-light customers' load may be only about a third that indicated by the sum of their maximum demands and a fifth that shown by their installed fixtures.

It cannot be said that reading meters and rendering bills quarterly instead of monthly is impracticable, nor that it would impair the finances of the companies, since many prosperous water companies follow this plan and have always followed it.

There is, however, a large opportunity for saving in the waterworks field also, for we have been surprised to find that even here a considerable number of the works are incurring the expense of rendering monthly bills. A committee of the American Water-Works Association, which compiled data on American waterworks rate [illegible], secured information on 447 plants out of the 5000 odd probably in existence. The committee's tables show that of 276 of these works operating on a meter basis, 111 render accounts for the most part quarterly and 165 monthly. The figures for the quarterly and monthly arrangements, respectively, are proportioned as [illegible] for the New England and North Atlantic States, 54 and 51 for the Central and Middle West, 7 and 20 for the Far West, 11 and 39 for the Southern and South Atlantic. Probably in a majority of the remaining waterworks, which are the smaller ones of the country and in which presumably meters are the exception rather than the rule, the payment takes the form of an annual assessment or "tax," so that the actual proportion of monthly bills to quarterly or less frequent ones for the whole waterworks industry is insignificant.

The Prospects for South American Trade

The number of engineers and business men who on account of the current depression of industry in the United States are looking for openings in South America [illegible] the article by Cyrus Townsend Brady, Jr., published elsewhere in this issue, is particularly timely. Mr. Brady writes with an intimate knowledge of South American conditions and his statements are corroborated also by other well known engineers who have had experience there.

It is to be borne in mind, however, that Mr. Brady writes of South America as he has known it during the past dozen years, while during the past two months the most revolutionary change that history records has swept over the financial and industrial world. The question what effect this change is to have on the commercial relations of the United States with South America is an exceedingly difficult one.

Broadly speaking, South America imports all its manufactured goods. In 1913, its total imports were valued at $1,304,000,000, of which $417,000,000 came from the United States. The exports of France, Germany and Belgium to South America were valued at $568,000,000, and Great Britain's, $322,000,000. The great bulk of the exports from France, Germany and Belgium are now cut off and if South America were to continue to purchase at the same rate as in 1913 it would probably tax the surplus capacity of the factories in both England and the United States to supply the demand.

At present, however, all accounts agree that the European war and its accompanying financial stringency has paralyzed commerce and industry in South America. Business conditions appear to be worse there even than in the countries of Europe outside the immediate zone of military operations.

South America has long been accustomed to do business on very long credit. It is claimed that one of the methods by which Germany has secured so large a portion of South American trade is by the cooperation of the German banks and trading companies with German manufacturers, so that orders have been secured in competition with manufacturers of other nations largely on the basis of the long period of credit extended. Very few American manufacturers are willing to do business under such conditions, nor are their banking facilities such as would permit them to do so.

Traders in South America, while they would be glad to purchase American goods when their supply from Europe is cut off, have not the money to pay for the goods and have, moreover, no way of obtaining the money. They can no longer borrow from their European connections, and, worst of all, the exports of raw materials to Europe, on which in the end South America relies to finance its imports of manufactured goods, have been cut down to very small proportions by the paralysis of European industry. The whole situation furnishes in fact an object lesson of the economic truth that international trade after all rests on the basis finally of barter. The transfer of gold is only a means of settling trade balances. In the long run a country can only import large quantities of manufactured goods by sending abroad a volume of exports of substantially equal value.

That was a most interesting incident in international trade that occurred last month when a vessel arrived in the port of New York from Iceland, commissioned by the government of Iceland to purchase wheat and other foodstuffs required by the inhabitants of that far northern land for their winter consumption and bringing to pay for them not gold coin or bullion, or drafts on European bankers for gold, but a shipload of fine wool, [illegible] fish, and other marketable products of the far north.

In order to increase our export trade to South America, therefore, the first step will be to increase our imports of South American products, the European market for which has failed. This can be done to some extent without doubt; but we are already South America's largest customer, buying over $500,000,000 worth from her last year. But South America exports to other countries over a billion dollars worth per annum. Any increase in our purchases would be only a drop in the bucket compared with the vast amount that Europe normally draws from South America.

Much of the South American export trade to Europe, however, must be soon reëstablished. The meat and grain of Argentine are essential to Europe's food supply; the nitrates of Chile are essential to maintain the production of European farms. It is equally true, however, that with the resumption of South America's export trade to Europe will come the reëstablishment in large part of the supply of European manufactured goods. British manufacturers are eager to recapture the world's markets which they have lost under stress of German competition.

At present, on account of the enormous number of men withdrawn from active production for military service, industry is stagnant in all European countries, except in industries directly connected with the supply of articles for military use. This worldwide paralysis of trade and industry cannot long continue. While the destruction of capital and the consequent financial stringency the world over resulting from the war are indeed of prime importance, it is to be remembered that the area over which actual military operations have extended is after all of trifling extent. Were hostilities to cease tomorrow, practically all of Europe's factories would be ready for operation for the world's supply of goods. The shortage of capital and of employees will have a certain effect it is true; but there is a large surplus population available to draw upon, the lines of trade are already established, and with the absolute necessity of the export trade to prosperity, it may well be believed that Germany will again be a strong competitor in the export trade not long after peace is declared.

While, therefore, the European war does unquestionably offer certain opportunities never before presented to American manufacturers and exporters, the business will have to be conducted with intelligence of a high order in order to win and hold the customers.

It must be said with great regret that the immediate opportunities for employment in South America of engineers who seek employment solely and have to live on their salaries are anything but encouraging. In fact, while steamers are taking from the United States to South America certain hustling manufacturers' agents and fortune seekers, returning steamers are bringing back to the United States engineers and skilled workmen who were engaged on South American enterprises a few months ago and were thrown out of their positions by the suspension of all industry when the war broke out.

It has been often and truly said that South America is a land of enormously valuable natural resources. There are without doubt a great number of opportunities for men with capital and brains and a knowledge of the country to build up various lines of profitable industry. The drawback to such ventures is the uncertainties as to governmental stability in the various Spanish-American countries. The losses suffered during the past three or four years by Americans who had money invested in Mexico have been extremely discouraging to those promoting investments in the countries farther south. With the high rates which capital can command in the United States on perfectly safe investments under conditions which are likely to prevail for some time, it must take very dazzling promises of profit to induce American capitalists to venture upon South American enterprises.

The Progress of the Steam Turbine Driven Centrifugal Pumping Engine

The City of Philadelphia was recently awarded a contract for two 20,000,000-gal. steam-turbine driven, geared centrifugal pumps to operate against a total head of 330 ft., under a duty guarantee of 145,000,000 ft.-lb. per thousand pounds of steam. The firm which is to build these machines, the De Laval Steam Turbine Co., Trenton, N. J., has also orders on hand for two 24,000,000-Imperial gal. pumps of similar design for the Toronto water-works, operating against a 268-ft. head, and two 6,500,000-gal. pumps operating against a 273-ft. head, for the water-works of San Antonio, Tex. A half dozen other machines of similar large power and capacity, built by the same company, are already in operation in a number of city water-works. These installations are of much interest, as indicating the strong position which the centrifugal pumping engine has already attained as a competitor of the reciprocating pumping engine. The probabilities seem strong that the centrifugal pump is destined to triumph over the reciprocating pump, just as the steam turbine has triumphed over the reciprocating steam engine and well nigh driven it from the market.

It seems no very long time ago that the centrifugal pump was first developed for use against high heads. At the Paris Exposition of 1900, Sulzer Bros., of Zurich, Switzerland, had a notable exhibit of multi-stage centrifugal pumps designed to operate against heads of several hundred feet. The claims for high efficiency made for these pumps were received at the time with a good deal of skepticism. The centrifugal pump was at that time a well known machine, but it had always been designed by rule of thumb, its use was confined to low heads and it was never expected to give high efficiency. The European designers applied scientific principles to the construction of centrifugal pumps, and revolutionized the machine. Pump builders in the United States promptly followed the lead of the Swiss and German designers, and high-speed high-head centrifugal pumps were shortly attainable in the American market.

It was not, however, until the steam turbine was developed to be a machine of high efficiency as well as high speed that the possibilities of the centrifugal pump began to be realized. Development in the steam-turbine field has been so rapid in the past seven years that it has been difficult to keep pace with it. The steam turbine is a machine demanding high-class workmanship and most careful and scientific design. The early steam turbines were prone to serious trouble from stripping of the blades, and were very apt to be extravagant in steam consumption. The steam turbine of the present day has attained

a very creditable degree of economy, and what is still more important, it retains its original economy in service very much better than does the average reciprocating engine. From the commercial point of view, the centrifugal pump is aided in taking the lead because steam-turbine construction has now been reduced to such a system that high-speed machines can be turned out at a cost far below the cost of building a reciprocating engine of the same power. Such high-speed machines are not only peculiarly adapted to driving electric generators of low cost, but also to the driving of high-head centrifugal pumps.

The high-duty reciprocating pumping engines of large size may well be called a monumental triumph of mechanical engineering. Its full efficiency is still materially higher than the best that the turbine-driven centrifugal pump can show, but a high-duty reciprocating engine of large power is an enormous machine, which requires a costly foundation and a huge building to house it. The steam-driven centrifugal pump of the same capacity is a machine with hardly a tenth part of the weight and size of its giant competitor. All the progress in mechanical engineering in numerous fields during the past half century has been toward the adoption of high-speed rotary motion and the abandonment of slow-speed reciprocating motion. There seems good reason to believe that the steam turbine will eventually win out over the reciprocating steam engine in the pumping-engine field as it has in so many other fields where the reciprocating engine was formerly the only type of prime mover.

Letters to the Editor

On Engineering Opportunities in South America

Sir—I have just read the letter of Cyrus T. Brady, Jr., published in ENGINEERING NEWS of Sept. 3. For some time I have had in mind the desirability of writing something very similar, but owing to press of other work have put the matter off. The case is stated so well in the letter referred to, that there is little to add to it, but I have had so many letters from engineers and others who think there are great opportunities in South America, that I think it is worth while to ask you to publish this, in confirmation of what Mr. Brady has said.

I do not mean to say there are no opportunities at all, but that they are comparatively few, whether for the professions or for commercial enterprise and require trained and experienced men to take advantage of them. It seems particularly necessary at this time to warn against too much optimism in regard to any great expansion of American trade with South America, which it is entirely improbable will take place, though we may be able to lay the foundations for expansion along certain lines of industry, if the situation is properly handled.

F. LAVIS.

New York City, Sept. 16, 1914.

Sir—The two letters of Cyrus T. Brady, Jr., in your issues of Apr. 30 and Sept. 3 are so inexplicably carried on all the [illegible] contained therein that the writer did not feel the necessity of commenting on them, [illegible] E. L. Verveer's letter in your issue of Sept. 17, criticizing Mr. Brady, the writer has thought that the testimony of an engineer who lived 15 years in Argentina would be welcome to Mr. Brady and interesting to your readers [illegible].

Mr. Brady has given a short [illegible] account of conditions in Argentina and the cost of the various articles he mentions are given undoubtedly in U. S. dollars and cents. The writer never wore a pair of boots while in Argentina that cost less than 14 or 16 paper dollars, or about 7 or 8 U. S. dollars, nor a suit of clothes that cost less than 60 paper dollars, or 30 U. S. dollars. The same quality of goods would cost in this country just about half those prices.

It is true that food stuffs raised in the country are not very dear—Mr. Brady didn't say anything to the contrary—but, what sort of a house would Mr. Verveer get in Buenos Aires for, say, \$70 U. S. currency per month?

Mr. Verveer seems to have an exaggerated idea of the role the French have played in Argentina. With the exception of a short narrow-gage railway in the north of the province of Santa Fe and the port of Rosario, which, curiously enough, is also in the same province, the writer does not recollect any other big engineering enterprise carried out by the French.

As pointed out by Mr. Brady, most of the engineering enterprises are English, while the Germans have also a good share. The fact of the matter is that Argentina, with true business instinct, always tries to secure the best talent regardless of nationality. And so it happens that when the magnificent port at Bahia Blanca was constructed the job was put in the hands of Senor Luiggi, an Italian engineer of international reputation.

That "so many Argentines have [illegible] sent their sons to France to study engineering" is far from being the case. If Mr. Verveer goes into statistics he will probably find that there are at Cornell more Argentine students than at any engineering college in France, and that by far the largest number of students go to Britain, Germany and Belgium, in normal times, of course. In the latter country, it may be remarked en passant, the University of the unfortunate Louvain granted degrees [illegible], that is to say, which were of no use whatever in Belgium itself.

British influence has been infinitely more powerful than that of the French. In spite of the difference in religion, there are several British schools in and around Buenos Aires which are largely attended by the natives. British sports have become all the rage and in the comparatively short time of 20 years Association Football—thanks chiefly to the efforts of A. W. Hutton, Esq.-

tor of the English High School—has become a national pastime.

Apart from his ideas as to the cost of living and as to French influence in Argentina, Mr. Verveer is quite correct in his assertions, and any engineer intending to go to that country would do well to read his interesting letter.

M. J. LORENTE.

Stone & Webster Engineering Corporation,
Cambridge, Mass.

The Cleveland Municipal Electric Plant

Sir—I have read, in your issue of July 30, the editorial article on Cleveland's new municipal electric plant. I have much interest and complete sympathy for some of the general observations contained therein on relations between electric central stations and the public which they are supplying. I am disposed to believe, however, that the editorial in question falls into error by comparing a utility having a restricted supply with one supplying, and under obligation to supply, an entire community.

It will be conceded generally that an electric central station which is privileged to limit the scope of its operations and to select its territory and customers can show more favorable results than one which is under obligation to supply an entire community. The Cleveland municipal plant is not embarking on the business of supplying the entire people of Cleveland with electricity. It is undertaking to supply a few people and it is in a position to pick its own territory and its own customers. From all that appears, the problem of the management is not to limit the number of customers whose rates will be less than the assumed average cost of 1.96c. but to prevent an influx of customers who will pay the maximum rate of three cents.

The editorial states (p. 261) that "the new municipal electric plant can serve only a small part of Cleveland's great area and seven hundred thousand population." The maximum station capacity is stated to be 25,000 kw. This plant is compared with a company having 100,000 hp. in station capacity and a "distribution system covering nearly the entire city." It does not appear that the municipal plant will reach any considerable proportion of the consumers in Cleveland who, because of their small lighting loads would be confined to the 3-c. maximum rate. Consequently the 3-c. rate is of little if any advantage to the residence lighting consumer.

Your criticism of private company rates, be it noted, extends not to rates afforded power consumers but to what you would have considered a traditional 10-c. maximum for residence lighting. In a city the size of Cleveland, the actual cost of reading and maintaining the average consumer's meter, of keeping his account and of collecting his bill is probably no less than 50c. per month. At the 3-c. rate it would require a consumption of 16⅔ kw.-hr. per month to pay the consumer's cost alone, not to speak of direct and fixed charges on the current consumed and its distribution. A company supplying the entire city at a maximum rate of 3c. would have thousands of customers whose monthly bills would range between 25 and 30c. and $1 at the outside. The company could better afford to give its service gratis to many of these than attempt to collect the small bills resulting from a reading of meters. As originally announced, the rate schedule for the Cleveland municipal plant contained no minimum charge. If a fair minimum is applied, the maximum actual charge in the case of those for whom the greatest solicitude is shown would greatly exceed 3c. The fact seem to be that the 3-c. maximum rate is a fiction in that its application is to be restricted by limiting the customers to whom service is rendered; some selective device must be employed as admittedly there is not enough capacity for the entire city.

The editorial carries its own refutation in the extracts previously quoted therefrom of its characterization of the Cleveland enterprise as "businesslike municipal competition." It is not competition for a municipality to set up an electric plant to take the cream of the business of a private company. Rather is it a modern form of highway robbery. The average railroad rates in the densely populated trunk-line territory are much lower than average rates in the sparsely settled Western classification territory. British tramways have lower nominal rates of fare than American street railways but the miles of track per unit of population are far less. The duty to serve entire communities is a heavy responsibility resting on central-station companies which must inevitably affect the rate so long as there are material differences in the use made of the facilities by different classes of consumers. Your editorial says: "If, however, a city like Cleveland can supply its citizens with electric current produced at lowest cost from an uptodate plant there is no need of interference by commission or courts." By your own admission the city of Cleveland is attempting to do nothing of the kind. On the contrary, it is imposing a heavy responsibility on all of its citizens for the supposed benefit of a favored few in an enterprise which will redound ultimately to the disadvantage of all through the violation of an economic law that monopoly most advantageously can conduct a business characterized by increasing returns.

As your editorial states, the Cleveland experiment is one of national importance. If it were conducted under laboratory methods, and with supervision not tinged with the suspicion of political motives, one would be obliged to accord it full and complete approbation—but for the fact that it does not attempt to solve the really important problem of furnishing electricity to all of the people of the city, including those residing in outlying and sparsely settled sections as well as those affording the best load conditions. As it is, however, Cleveland's experiment deserves nothing but severe condemnation, for, even if experience demonstrates that this small plant can be operated under ideal conditions at extremely low rates, the world will be no wiser as to the exact cost of caring for the needs of entire communities and Cleveland will be paying in the aggregate more for an inferior divided service than it would be required to pay under conditions of closely regulated monopoly.

WILLIAM D. KERR.

Director, Bureau of Public Service Economics.
17 East 38th St., New York City.
Aug. 29, 1914.

[Opportunity was extended to F. W. Ballard, Commissioner of the Cleveland Division of Light and Heat, to

comment on the foregoing criticisms. This he has done in the following letter.—Ed.]

Sir: I have read with much interest the letter of the Director of the Bureau of Public Service Economies of New York City in reply to your editorial on the Cleveland Municipal Electric Plant.

It is quite evident that he is not well informed in regard to the conditions in Cleveland, particularly as to the amount of territory which is being served by the municipal light plants. He draws some very odious comparisons tending to show the small and restricted area which is to be furnished by the new municipal plant as compared with the territory which is furnished by the privately owned plant in Cleveland. As a matter of fact, the amount of territory covered by the distribution system of the municipal plants is very much greater than that furnished by the privately owned plant, when considering the relative size of the stations. The small Brooklyn station, which has been in operation for about ten years, and which has only a capacity of 150 kw., or 1½% of the capacity of the large privately owned station, has a distribution system covering some ten square miles of territory. Instead of being the "cream" of the business, this territory is almost entirely the residence sections of the city, and largely consists of the suburbs. The privately owned company's distribution system covers the business part of the city, and has all the large customers, and in reality has had the "cream" of the business, or in other words, that part of the business which really pays the best profit. This small plant is the one which secured the good results set forth by the figures in the editorial of the Engineering News referred to.

Also I note that in Mr. Kerr's letter he states that the rate schedule for the Cleveland Municipal Plant contains no minimum charge. He seems to be misinformed on this point, as there is a minimum charge of $.50 for each customer, intended to cover the cost of billing and collecting.

As all the arguments set forth in his letter are based upon these two assumptions, which are entirely erroneous, very few will agree with him in his conclusion that "Cleveland's experiment deserves nothing but severe condemnation."

F. W. Ballard, Commissioner and Chief Engineer,
Division of Light & Heat.

Cleveland, Ohio, Sept. 26, 1914.

A New Harbor Map of Philadelphia has been prepared by the Department of Wharves, Docks and Ferries, and is now ready for distribution. It is [illegible] in. and shows the Delaware River and the navigable section of the Schuylkill within the city limits with all wharves, bulkhead and pierhead lines and channel and [illegible], as well as the present depth of water in the channels and at the docks.

A Bill Requiring Engineers in Pennsylvania to be [illegible] [illegible] in order to practice their profession has been drafted by a committee of which Prof. John P. Jackson, of State College, Penn., is the chairman, and the other members are [illegible] A. Taylor, George S. Webster, F. Herbert [illegible] and J. [illegible]. The bill requires every [illegible] [illegible] of the engineering profession other than [illegible] engineers [illegible] after June 30, 1914, to be registered as a professional engineer, and provides for examinations by a [illegible] board of [illegible]. A fee of $[illegible] is [illegible]. [illegible] on the proposed bill were held by the [illegible] of the [illegible] Society in Pittsburgh, Oct. 15 and [illegible] the Engineers' Club of Philadelphia, on [illegible] [illegible] and [illegible] at the Engineers' Club on Oct. [illegible]

A Humphrey Direct-Acting Explosion Pump for Irrigation Service at Del Rio, Texas

The first installation in this country of a large-size Humphrey direct-acting explosion pump, now being made on a Texas irrigation project, is of unusual interest. It will be used by the G. Bedell Moore Estate, which has planned for some time the irrigation of a tract along the Rio Grande, of twelve thousand acres, between Del Rio and Eagle Pass.

Alexander Potter, Consulting Engineer of New York City, was retained to pass upon the most economic plan of development and recommended pumping, preferably by Humphrey pumps, instead of a long and hazardous gravity canal. The Moore Estate commissioned Mr. Potter to study the European installations of this type and the detail plants of the immense Mix (Egypt) plant now under construction. As a result of these investigations, together with a study of the original research work done by the American company, the Moore Estate has purchased Humphrey pumps and Akerlund-type producers for wood and coal burning.

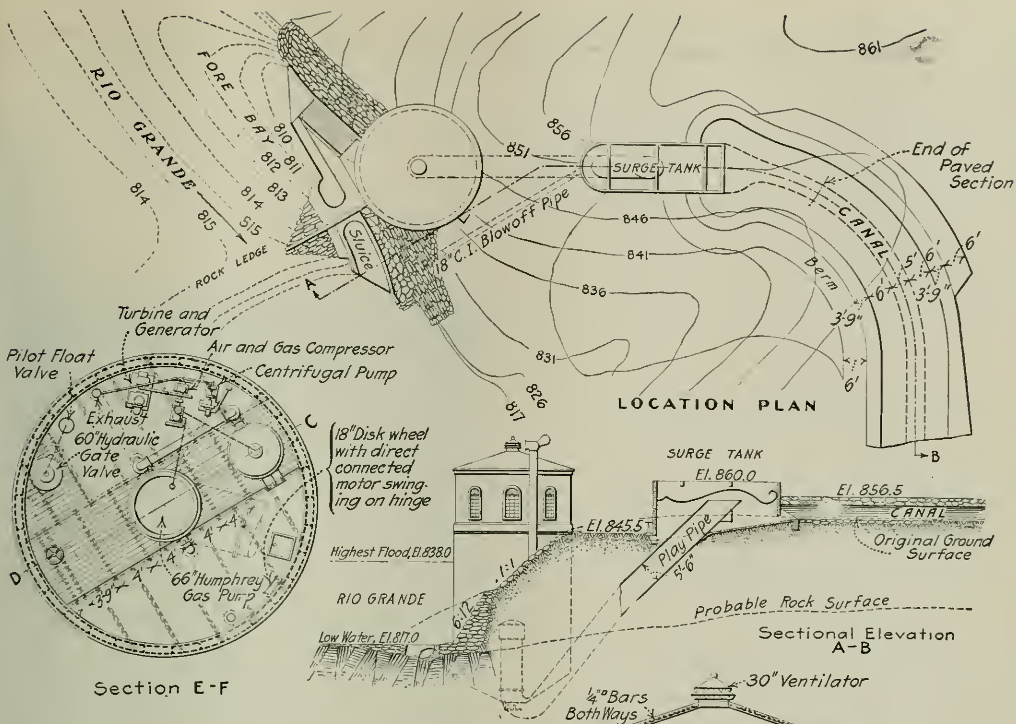
Use of Humphrey Pump.—In designing the pumping plant, two types of machinery units were studied: (1) A centrifugal pump driven by an internal-combustion engine; and (2) a Humphrey direct-acting explosion pump. In the decision to use the latter, the kind of fuel that could be obtained at the pumping station played an important part.

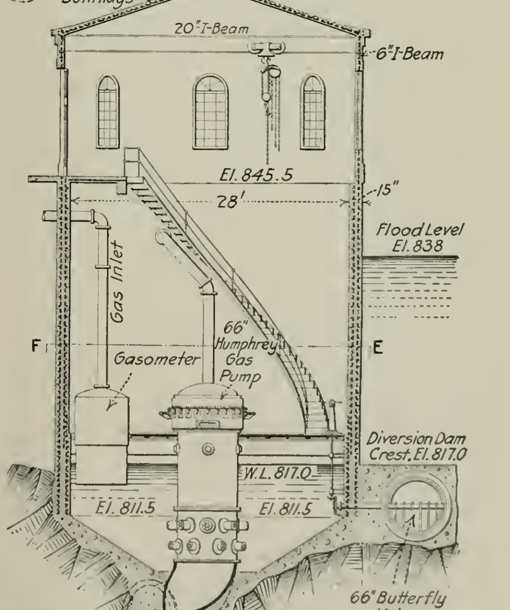
The pumping station is located some 15 miles by road from Del Rio, the nearest railroad station; Eagle Pass bituminous coal could be delivered at the plant for $4 per ton, while fuel oil would cost some $2 per bbl. Much of the land is covered with mesquite wood and will have to be cleared before cultivation. Therefore, the use of this wood as fuel until clearing was completed seemed attractive and its possibilities in gas producers has been fully investigated with highly satisfactory results to the purchasers. The estimated fuel consumption per 24 hours and fuel cost per acre-foot for a plant of 67 sec.-ft. capacity under 37 ft. lift, was as follows:

	Fuel	Consumption per 24 hr	Fuel cost per acre-ft.
Humphrey pump and gas producer	wood	[illegible] cords	$[illegible]
	coal	[illegible] tons	$.1[illegible]
Centrifugal pump and Diesel engine	oil	11 bbl	0.311
Centrifugal pump, gas engine and producer	wood	11.[illegible] cords	0.1[illegible]
	coal	[illegible] tons	0.1[illegible]

Thermal efficiencies: Humphrey pump [illegible], gas engine, [illegible]; Diesel engine, 32%; gas producer on lignite fuel, [illegible]; gas producer on wood fuel, [illegible]. Mechanical efficiency of centrifugal pump, 65%. Coal of [illegible] B.t.u. per pound at $4 per ton. Fuel oil of 19,000 B.t.u. per pound at $2 per barrel. Mesquite wood at $1.50 per cord ([illegible] lb.), [illegible] B.t.u. per pound.

Pumping Station.—The pumping station, as shown in the accompanying general plan is located directly upon the banks of the Rio Grande River at a point where a rock ledge extends entirely across and creates a slight fall. A forebay is being excavated in the river bed adjacent to the pumping station and just above the ledge. At the downstream end, the forebay is being closed by a small concrete dam and in this is placed a 66-in. circular sluiceway which can be closed by a [illegible]-in. butterfly valve operated from the interior of the station. Normally, this valve will be kept open so as to keep the forebay free of silt deposits, as the river is very muddy. The intake to the pumping station is 5 ft. in diameter. At its outer





Irrigation Pumping Station of Moore Estate, Del Rio, Texas

end it is protected by a screen inclined at a slope of 1 on 3. It has been assumed that no trouble will be experienced in keeping the screen free of floating débris as this will have a tendency, because of the flat slope, to work upward and gradually clear itself.

The Humphrey pump is now nearing completion by the owners of the American patents, the Humphrey Gas Pump Co., of Syracuse, N. Y. It is guaranteed to pump a minimum of 28,000 gal. per min. against 37 ft., though the designers are confident of showing 30,000 gal. on test and the hydraulic works have been designed for the latter figure. The guaranteed thermal efficiency is 20% when using producer gas of over 100 B.t.u. per cu.ft. The pump and play-pipe are 66 in. in diameter, the latter being 100 ft. long.

The pump is housed in a reinforced-concrete well, 34 ft. deep, shown in the accompanying figure, designed to resist the full hydrostatic pressure of flood waters. The operating floor is 3 ft. above the lowest river level. The water level in the pump well is maintained at constant elevation, irrespective of the river stage, by a float-controlled hydraulic gate valve operated by pressure from the high canal.

A gasometer is placed in the gas main leading from the producer to the pump. This, for safety in case of backfires, is a steel tank with the lower end open but sealed by the water in the pump pit.

The following accessories are also to be installed in the pump pit: (1) a 1-kw. electric generator direct connected to a small turbine operated by water from the canal; (2) a two-cylinder air compressor which can be driven either by the turbine or by an explosion engine operated

or producer gas or gasoline, and a small centrifugal pump belted to the gas engine of the air compressor for draining the pump well.

Special attention has been given to ventilating the pump house. The top of the conical roof of the superstructure is provided with a 30-in. exhaust cowl. Fresh air is admitted to the pump pit at the operating floor level through a 24-in. pipe with a top cap designed to force air down by wind action. The pipe opening into the pit carries an 18-in. motor-driven blower on hinges so as to be swung into place for service when the wind velocity is too low to secure sufficient natural ventilation.

The play-pipe discharges into a reinforced-concrete surge tank 36x12 ft. The discharge pipe extends 9 in. above the normal water level in the canal. The guaranteed lift of the pump is fixed at 37 ft., as this is not sufficient to irrigate a tract of some 500 acres in the immediate vicinity of the pumping station, it is intended to use the wave action in the surge tank to raise a small quantity of water 4 or 5 ft. above the elevation in the supply canal. The arrangement for this is not shown on the accompanying figure. The surge tank is also designed to act as a grit chamber, the grit to be washed in to the river through an 18-in. cast-iron pipe.

PUMP OPERATION—The operation of the Humphrey-type pump has been noted in ENGINEERING NEWS from time to time (particularly in the issues of Dec. 2, 1909, p. 601; Apr. 17, 1913, p. 764; Dec. 25, 1913, p. 1331) so that it will be but briefly noted here. A charge of gas-air mixture is exploded in a chamber above the water surface, no piston being used. The explosion drives the water downward, closes the water inlet valves and sets the whole water column in the play-pipe in motion. The inertia of the moving column of water permits the burned gases to expand below atmospheric pressure when both exhaust and water valves open. There follows a return surge of the liquid column until the water reaches the exhaust valves and closes them by impact. There is a second forward surge set up by the trapped and compressed gases and when the pressure again falls below atmospheric a fresh charge of gas and air is drawn in. This is finally compressed by the second return surge and exploded, when the cycle repeats. The inlet and exhaust valves are interlocked so that the proper sequence of operation is maintained.

In the American adaptation of the Humphrey design, the complicated arrangement of rods and bell cranks by which the interlocking is accomplished on the large Chingford pumps in England, has been superseded by a simple eccentric chain [illegible] around the valve belt engaging ratcheting studs and moving a short distance first in one direction and then in another to shift the lock from one set of valves to the other. The period of oscillation is about proportional to the square root of water column length; in this case the pump will have approximately 18 cycles per minute.

There will be two types of ignition equipment: (1) Jump-spark (high tension) from storage batteries and coils, and (2) "wipe-spark" or arc ignition taking current from the [illegible] generator. To start, an initial charge of gas and air will be forced in by compressed air, all the valves being held shut. After explosion the play-pipe oscillations thus initiated are strong enough to work the valves and make the pump begin regular operation.

GAS-PRODUCER PLANT—The producer house will be located very close to the pump house on higher ground.

The producer system is that of the Standard Gas Power Co., of New York. It comprises a vertical down-draft generator with a water pan on top and a vapor ring around the combustion belt; air is admitted to the vapor ring and the mixture of air and steam enters the fuel chamber above the green charge. The gas is led off through a spray-cooler, a wet scrubber, exhauster, dry purifier and delivery pipe. The following figures were obtained on trial runs of the producer with mesquite wood:

Average wood burned per hour	416 lb.
Average gas made per hour	[illegible] cu.ft.
Average gas made per lb. of wood	[illegible] cu.ft.
Average B.t.u. per cu.ft. of gas	111.5
Average lb. of wood per sq.ft. of fire area	[illegible]
Lb. of wood per horsepower-hour	1.76

The pumping plant will be completed by Jan. 1, 1915. The construction of the pumping station, intake works and canal is being executed by company forces. Mr. J. H. Savage is General Manager of the Moore Estate. Whiteaker & Washington, Engineers, San Antonio, designed and are in charge of the canal work.

Water Disinfection by Liquid Chlorine at Wakefield, Mass.

BY EDWARD C. SHERMAN*

The water-supply of Wakefield, Mass., is taken from Crystal Lake, in the outskirts of the town, and pumped directly into the mains, a stand-pipe serving to take the excess and to afford a night supply. The lake, although fed by many springs, receives considerable surface water which, with increase of population on the watershed, caused the quality of the supply to become unsatisfactory at times.
